DR. E. L. PARKS stated that he passed the winter of 1877–78 in Santa Barbara, which proved to be a most delightful place of residence. There is no malaria in the town or neighborhood. The extreme between the coldest temperature of winter and the warmest of summer is but forty degrees. These statistics are thoroughly reliable, as they were taken by a gentleman, a physician, who was advised to go there for the benefit of his health, which was fully restored. He remained perfectly well as long as he resided in this place, but he could not live elsewhere, and as a pastime he made a series of careful observations upon the meteorological conditions of the place. The relative humidity is a thing which is a source of the greatest disturbance to many delicate patients. Often a patient who cannot live at the level of the sea will be perfectly comfortable at an elevation of 400 feet above the sea.

In a case of this kind the humidity alone is variable, all else remains unchanged. Another thing which is often a cause of disappointment in the effect produced by residence at any health resort is the way in which patients are allowed to make the journey to the new abode. Very frequently a sick person arrives without an attendant, he is not welcome, he may not be able to secure good or comfortable accommodations, and he is entirely at the mercy of those who may be willing to receive him. A case of this kind was known to the speaker, in the person of a gentleman from Boston, now deceased. He came unattended and unknown, he was unable to secure good accommodations, and was not comfortable during his short stay there. Aside from this, he was in a condition quite unsuited to travelling, and should never have been sent from home. A patient may go to Santa Barbara at a certain stage of pulmonary disease, and by a prolonged residence, never less than a year, may quite recover. It is, however, worse than useless to send a patient to Santa Barbara after all the other resorts have been tried. These cases will not be benefited by the climate of Santa Barbara or that of any other resort. When a patient has reached a certain stage of the disease, there is no benefit in change to any other climate.

DR. E. W. CUSHING said that the peculiar geological formations at many of the resorts for invalids, such as various parts of California, Nice, Cannes, etc., allow the patient to choose exactly the situation and the surroundings adapted to his comfort. The country rises rapidly from the seashore to the hills, so that an elevation of considerable magnitude may be attained at a short distance from the town, and within a short time from the sea-level. That it is not the "humidity" alone, or even to any great extent, is now generally admitted. The change of scene, the entire rest, the out-of door life, and the relaxation from all labor, are important factors in the amount of benefit to be obtained from a stay at any health resort. One of the most useful adjuncts to all the other measures which may be adopted is exercise on horseback. Given good food, rest, trees, music and suitable companionship, with the advantages of good society, a sick person will often obtain great benefit from a stay at any proper resort. Throughout the South, however, the boarding arrangements are bad and the accommodations wretched. Another objection to many, if not most "health" resorts is the fact that one place after another fills up with phthisical patients, there is often no suitable water supply, and even more frequently no suitable provision for drainage, and the entire place at length becomes charged with the disease, the rate of mortality rises, and the place is ruined as a health resort

Dr E I Eastman thought that the most important object to be attained is the comfort of the patient A sick person who is sent to a place where many consumptives are herded together, is quite easily depressed, and may die from the moral effect of such melancholy surroundings No doubt each year many persons die in such places who might recover under more cheerful circumstances Above all, in the present state of our knowledge of pulmonary disease, we should avoid the crowding of phthisical patients

Dr Knight said that it was gratifying to see that physicians had begun to use some discrimination in recommending climates The discussion had been mostly restricted to the benefit of change of climate in pulmonary disease, but of course there were many other diseases which might be benefited by an appropriate change

A great and beneficial modification of the custom of sending all cases of pulmonary disease to warm climates has taken place in recent years, a custom which has arisen from giving too much consideration to what might mitigate the concomitant bronchitis There is no doubt of the great difference in the physical properties of different climates, and no doubt that we can favorably modify pathological conditions by taking judicious advantage of them

In selecting a climate for consumptives, the peculiarities of each patient should be considered, his temperament, the stage of his disease, complications, etc If permanent arrest of the disease is hoped for, Dr Knight said that he was always glad if the patient's condition is such as to allow of the selection of a dry mountain climate of considerable elevation If his peculiarities will not admit of this, then a lower altitude, but still a dry and tonic climate, should be chosen It was unfortunate if a warm, moist climate had, for any reason, to be adopted

Dr Herman F Vickery read a paper entitled

ENLARGED CERVICAL GLANDS

(See page 313)

Dr John Homans thought that many other causes may exist for enlarged glands besides those mentioned in the paper Thus, rhinitis, pharyngitis, and tonsillitis may cause enlargement of the cervical glands These are, however, the expression of a general systemic condition, and are not dependent upon the local state of the neck

Dr Barker mentioned the enlargement of the glands of the neck following surgical operations as illustrating another causation of this condition

Dr Vickery said that the enlargement of the glands seems often to be secondary to other conditions Thus, a child pricked the neck with the tine of a fork, to a moderate extent The prick healed quickly, but soon after there was noticed a distinct enlargement of the glands of the neck which proved to be not adenoma, but scrofulous in character

Dr Edward B Lane read a paper entitled

TWO CASES OF CEREBRAL TUMOR, WITH AUTOPSY

Case 1 —James M , 37 years old, was admitted to the Lunatic Hospital August 3, 1885 Married, policeman, was born in Ireland Very little is known of his family, since none of his relatives are in this country Used alcohol daily, would occasionally drink more than he ought, but never incapacitated himself for duty on the Boston police force Is not known to have had rheumatism nor any severe illness previous to last January No specific history could be obtained

In January, 1885, he fell on the street, becoming unconscious and remaining so for half an hour Became conscious soon after reaching home but for more than a week his speech was thick and he swallowed with difficulty No other paralysis was known. Went on duty a month later Then his speech was much improved, but not quite clear Continued to perform his duties as usual until May, when he had a second attack, this time in the house Fell, but did not become unconscious He got up unassisted and sat down It was found that his right side was affected, the hand and leg of that side being weak but not completely paralyzed He was able to walk. His speech was not affected nor his ability to swallow impaired No facial paralysis was noticed He had no headache, either before or after this attack Slept well and ate well Regained the use of his limbs to a certain extent, but could not light a match with his right hand, could write, but his hand was tremulous Returned to patrol duty in two weeks and remained on duty until the middle of July, when he had an attack of vertigo while on the street Was sent home in a horse car Felt ill and stayed at home until admitted to the hospital a fortnight later After the second attack (in May) became irritable, and memory failed somewhat Became suspicious that men talked with his wife, and that she had had visitors

During the last two weeks at home his mental condition degenerated rapidly Memory grew weaker He was anxious to go to the Station house, and would become angry, though not violent, when restrained Delusions of suspicion developed Thought there were men concealed in the house and he procured a pistol and billy to defend his wife On admission, was seen to be a well developed man of medium size Too dull to respond to questions Was able to get about and use his hands fairly well Right eyelid drooped Pupils were equal, tongue protruded to right (probably accidental, as it afterward came out straight), not retracted Eats when fed but will not feed himself Will not stay in bed, and soils the floor Pulse 60 Patella reflex present No enlarged glands Denied syphilis Eyes examined Nothing unusual seen beyond a fulness of the veins of the fundus During the first week at the hospital, condition did not change much Would answer simple questions Had considerable difficulty in swallowing About this time he became comatose, with a temperature of 102 6, and respiration 44 Left pupil dilated He rallied to his former condition in the house He then gradually improved mentally[1] until at the end of the second week he knew his wife and conversed with her, and signed some documents But at no time did he realize where he was nor avoid wetting his bed When asked to put out his tongue would do so after waiting nearly a minute Memory was very weak, would not know his room but would wander about, upsetting furniture, etc After being in hospital a month was able to be dressed, saw an old acquaintance and chatted with him Told him that he had been on his beat that day Difficulty in swallowing almost entirely disappeared and he ate heartily At this time patellar reflex was found to be excessive and ankle clonus present Said he was "first-rate" About the middle of September (six weeks after admission) rapidly grew dull, swallowed liquid with difficulty In a few days febrile action appeared Was very obstinate, resisting everything done for him, fumbled the bed clothes and handled his genitals constantly Temperature varied from 99° to 103° Respiration persisted rapid, gradually rising from 30 to 50 Was very helpless, could scarcely swallow, and was so dull he would not speak, and in eighteen days from the onset of the stuporous condition died

Autopsy twenty hours after death by Dr Gannett Ratio of head to body and cranium to face, normal Calvaria thin The dura everywhere translucent and the sinuses contained dark fluid blood The pia slightly opaque about the convexities Its meshes contained a small amount of clear fluid The brain filled the cavity of the skull and weighed 1402 grms The vessels at the base and in the fissure of Sylvius showed nothing remarkable The pia anterior to the optic commissure showed a slight snuff-colored appearance, and on section showed several opaque grayish yellow globular nodules, varying from one to three mm in diameter, and each surrounded by a grayish-red translucent tissue for a distance of three to four mm These were directly continuous with the pia On the under surface of the right frontal lobe, adjacent to the pia, was a nodule the size and shape of an almond, except not quite so long, having an opaque grayish yellow centre the size of a large pea, and surrounded by a reddish gray translucent material like that already described In the lowest portion of the left temporal lobe at anterior extremity were several yellowish nodules about two mm in diameter, surrounded by a reddish gray translucent tissue At the junction of the anterior and middle thirds of corpus callosum and on the adjoining convolution in the anterior fissure were a series of yellow nodules of two or three mm in diameter arranged antero posteriorly, forming a line about four cm in length These were in turn surrounded by a similar reddish gray translucent material The lateral and fourth ventricles showed in the ependyma numerous fine granules presenting a warty appearance The floor of the left lateral ventricle over the basal ganglia showed two depressions about twenty mm in diameter On section in the left *nucleus caudatus* and in the left *thalamus opticus* were cavities the size of small filberts, formed by a mesh-work of fine lines and containing a snuff brown fluid In the posterior portion of the right *thalamus opticus* were two cavities each about the size of a filbert-meat, and presenting the same characteristics as those described The section of the hemispheres, pons, medulla and cerebellum showed no appearance worthy of special note The pia everywhere readily separated from the brain substance Heart and pericardium showed nothing worthy of note Examination of the other organs showed little of interest beyond diffuse bronchitis and tracheitis, chronic pleurisy and a nodule in the mesentery There was a scar on the penis

Diagnosis of lesions found in the brain Chronic lepto meningitis and œdema of the pia, each to a slight degree only Multiple gummata So called "apoplectic cysts" of the basal ganglia Chronic ependymitis

Case 2 —Mary J , 64 years old, of American parentage, a cloak room attendant, was admitted to the Boston Lunatic Hospital September 3, 1885 With her was sent the statement that she had been hemiplegic for nine days That she was at times incoherent and confused Was helpless and needed hospital care After her death the following history was obtained Family history unknown Seventeen months ago her husband died and his loss caused the patient much grief and worry Since death of husband she has been in very straitened circumstances

For the past six months has complained of severe headache and loss of memory, and when alone in her room would continually talk aloud to herself Appetite was good When not mindful of her loss was as cheerful as ever Continued to attend to her duties in a cloak room and to her household duties until eight or nine days before admission No serious sickness was suspected until she was found one morning to have right sided hemiplegia, to be almost speechless as well as perfectly helpless, having been apparently as well as usual the day before On admission to the hospital was seen to be a very large, well nourished woman She was helpless, having right sided hemiplegia Was very dull, but would answer a few simple questions

For four days after admission was dull and gave unintelligible answers Took a small amount of liquid food when it was placed in her mouth Could not eat, and swallowed liquids with difficulty Was noticed to call things by wrong names At the end of this time she became brighter, was not quite as helpless, could swallow a little better and could speak more distinctly It was now seen that she was partially amnesic, more accurately speaking, she was almost totally unable to recall names It was usually impossible for her to name objects She could not even recall her husband's name Was aware of her defect and seemed much annoyed by it When asked to name a bunch of keys she said "I cannot," then made an effort and pronounced "boots," and laughed at her failure Was then told to say "keys" She made another effort and said, "that is right, skewers," and laughed again But on being prompted a second time she pronounced "keys" properly Physical examination showed the right sided hemiplegia to persist, mouth was drawn to the left, tongue was protruded, straight, however, left eye was turned in, showing probable paralysis of the sixth nerve on that side from pressure, pupils were even, plantar reflex present Ophthalmoscopic examination was impossible Remained in this condition, conscious, but dull and listless, for two days Did not ask where she was nor seem disturbed by her new surroundings She continually complained of thirst She became more dull on the ninth day, and on the morning of the tenth was found comatose Had been vomiting Made automatic movement with left hand only Pupils were much contracted and pulse was 96, temperature 101 5 (P M) Coma lasted only twenty-four hours, and during the following day she gradually grew brighter and was as well as before the attack Condition of side, however, did not improve She gradually grew more intelligent and for a short time knew where she was, but probably did not realize the significance of it Remarked that she must be a difficult patient to care for, she was so heavy and helpless She became more restless, and would kick the bedclothes off with left leg Could use both hands a little Required to be watched or she would lie uncovered Gave no reason for it Was at this time asked if she were hungry and she replied "yes," was asked if she were thirsty and she said "yes," and to test the truth of her statement was given bread and milk Declined it saying she wanted something "brighter" She seemed aware she had not said what she meant When asked if she would prefer water seemed pleased and assented At another time asked for "fire," and then shook her head When asked if she meant water, said "yes, fire," and laughed at her blunder When "water" was slowly pronounced she repeated "w-water" Memory was much impaired, she could not remember whether she had eaten two hours after doing so On the seventeenth day, and a week after the brief period of coma, the patient grew more dull and helpless Would not swallow liquids, and gradually became comatose, sweating profusely and occasionally vomiting a greenish watery fluid Pulse was strong, but uneven and rapid Respiration was labored and noisy, tracheal râles persisting until death She continued in this coma five days, death being hourly expected Died on twenty-third day

---

[1] His mental condition was that of contentment. Speech was that of a general paralytic No delusion of grandeur was expressed

Autopsy was made twenty-two hours after death by Dr Gannett Nothing unusual was observed about the calvaria or dura Sinuses contained soft coagula The convolutions of the brain flattened and sulci obliterated, surface of pia dry The brain completely filled the cavity of the skull and weighed 1550 grms At a point in the left fissure of Sylvius where the middle cerebral gives off its numerous branches was a dilatation the size of a pea At a corresponding position in the right side was a parietal dilatation the size of a pin's head In the basilar artery was an opaque yellow patch in the intima about three mm in diameter The right lateral and fourth ventricles showed nothing remarkable The floor of the posterior portion of the left lateral ventricle was elevated, rounded and quite tense to the finger On section of the hemispheres there was found in the white matter of the left hemisphere posteriorly a rather firm opaque grayish-yellow nodule, the size and shape of a medium sized peach, showing on section here and there spaces filled with a thin cream like fluid The brain substance on the periphery of the nodule for a distance outward of about four mm showed to a very slight degree a punctate appearance The white matter lying just beneath the nodule was of soft consistency and grayish white color The white matter in general was rather pale, surface of usual degree of moisture, the cortex not remarkable Section of the basal ganglia, pons, medulla and cerebellum showed no appearances worthy of special note Examination of the other organs revealed nothing of interest beyond a large cyst occupying the upper third of the right kidney, pelvic calculi, and two firm gray nodules the size of a pea in the wall of the uterus A pedunculated polypoid tumor in the cavity of uterus Microscopic examination of the tumor has been begun by Dr Gannett, but owing to the hardening not being yet completed, he is unable to give a definite opinion He has kindly consented to offer the *probable* diagnosis of *vascular glio sarcoma*

Summary —In the first case, we have a young man with cerebral syphilis resulting in paretic dementia From the onset of mental derangement the course of the disease was unusually rapid The hemiplegia and the mental condition of hebetude and delusions cannot be said to follow the presence of the gummatous tumors, as the hæmorrhage in the caudate nucleus and the lepto meningitis are the lesions more usually associated with such symptoms No special set of symptoms can be referred to the tumors

The second case was remarkable in the fact that a large tumor must have been gradually developing in the mass of the cerebrum, causing for a long time only minor symptoms A woman able to do her daily work, neither general nor mental health being sufficiently impaired to attract attention, suddenly becomes comatose and hemiplegic She recovers consciousness and suffers two more relapses of coma and dies During the intervals of consciousness she is seen to be suffering from a partial amnesia Amnesia (oftener partial than complete) has been found to be associated in cases reported by Werwicke and others, with lesions in the occipital lobe The question might arise as to the possibility of there being an aneurismed dilatation causing the symptoms This is hardly tenable when we consider the great extent of pressure required to cause both hemiplegia and amnesia The vascular changes in the tumor must explain the suddenness of symptoms

Dr J J Putnam stated that cases of tumor of the brain often present no definite or recognizable group of classical symptoms, by which their location, or size, or frequently their existence, even, may be determined Dr Putnam mentioned a case seen in consultation with Dr Adams, of Watertown, in which almost all the tissue of the pons was replaced by a large vascular glioma

Dr P C Knapp asked the seat of the tumor?

Dr Lane stated that it was seated below the basal ganglia, and was evidently pressing upon the crus cerebri

Dr Cushing asked if the early recognition of the disease and its treatment by anti syphilitic measures is of any avail in cases of cerebral syphilis?

Dr Lane stated that no case is known in which the syphilitic lesion in the brain has been benefited by any form of treatment

Dr Goldsmith has never seen a case of improvement in such cases

Dr Putnam remarked that probably that does not mean that no case may be relieved by treatment

Dr Lane stated that no case in which the disease was of a sufficient degree of severity to require treatment in an insane asylum had ever been known to be benefited

Dr Putnam added that in the early stages of congestion, before deposits of syphilitic growth have taken place, it may be possible to improve the patient's condition When chronic paralytic dementia has occurred there may well be no improvement from any mode of treatment

Dr Knapp added that in cases in which any mental derangement exists there is no hope for any form of treatment

CHICAGO GYNÆCOLOGICAL SOCIETY

Stated Meeting, Friday, January 15, 1886

The President, Daniel T. Nelson, M D, in the Chair

W W Jaggard, M D, Editor

(*Continued from page 304*)

Dr E J Doering read a report of

A CASE OF HYDATIDIFORM PREGNANCY

After a brief discussion of the etiology and pathology of cystic degeneration of the chorionic villi, Dr Doering related the history of the following case

Mrs W D P, a cultured lady, of slender physique, 21 years of age, was attended by me in labor fifteen months ago, and delivered by instruments of a healthy boy weighing ten pounds Her general health has been good She has had no miscarriages either previous to or since the birth of her child Her last period occurred during the latter part of October, 1885 During the month of November the catamenia remained absent, which she attributed to a cold, the idea of pregnancy not occurring to her, as she had none of the usual symptoms During the month of December, and particularly during the week preceding the holidays, she was on her feet constantly although not feeling well, having sensations of chilliness, followed by a feeling of heat and general depression On the Sunday before Christmas a slight and painless flow of blood commenced, believed by her to be the period, now four weeks overdue The flow continued several hours and then ceased On Christmas day, while seated at the dinner-table, she was suddenly attacked with a profuse hæmorrhage, the blood saturating the floor, and continuing until a degree of faintness was produced, in which condition I found her on my arrival a few minutes afterwards The hæmorrhage, which had been entirely without pain, ceased suddenly A careful examination confirmed my suspicion of pregnancy, although I was much surprised at the size of the uterus, corresponding to a four and one half months' pregnancy, the fundus rising nearly midway between the symphysis pubis and the umbilicus There being no further hæmorrhage, no pain and no dilatation of the os, an expectant plan of treatment was pursued by instructing the patient to keep in bed, enjoining absolute rest, and giving her a few doses of morphia On the following night another hæmorrhage occurred, but of not much consequence, and requiring no interference Two days later, on the morning of the 28th of December, another hæmorrhage took place, more copious than the last one, but still unaccompanied with pain An examination showed slight dilatation of the os, but not sufficient to permit the recognition of the contents of the uterus As the patient was beginning to show decided symptoms of anæmia, the vagina was tamponed and ergot administered to check the hæmorrhage and favor uterine contractions

Uterine pains soon commenced, accompanied by considerable hæmorrhage, the os dilated fully one inch, the presenting part giving the sensation to the finger of a blood clot This was soon expelled in detached portions, and on removal from the vagina was readily recognized as a hydatiform mole, having all the characteristic appearance of a grape bunch, composed of a mass of translucent vesicles, about the size of currants, containing a clear, limpid fluid After inserting two fingers into the uterus and emptying it as thoroughly as possible of all the diseased tissue, the hæmorrhage promptly stopped The entire mass removed equaled about the size of a large orange Some febrile reaction occurred, but for several days the temperature did not exceed 100½F° and the pulse 95, the treatment consisting of quinine and ergot, internally, and the use of uterine and vaginal injections of carbolized water

On the beginning of the fourth day the patient was suddenly seized with a severe chill, followed by the usual symptoms of septic poisoning, high temperature (104½°F), rapid and feeble pulse, superficial respiration, great tympanites, thirst, vomiting, and arrested lochia, with no pain or tenderness over the abdomen The outlook was anything but promising, but the prompt administration of large doses of quinine, combined with diaphoretics, turpentine stupes, warm fomentations, and the continued use of antiseptic injections was followed by the most gratifying results, and after four days of great anxiety the patient had recovered sufficiently to be declared out of danger At the present time, eighteen days since the expulsion of the mole, the patient is up and about the house, with a good appetite, and making preparations to leave in a week or two on a journey to the South

Dr C W Earle had seen two cases of this kind, and while he had been surprised a great many times in his practice, he was never more so than upon one of these occasions He had been in practice about two years, when he was called to attend a lady in confinement near his residence He placed himself at her bedside, found the *os uteri* well dilated, with the membranes intact and well down in the vagina, when all at once there came a gush of something, and a large quantity of these grape-like bodies made their appearance He immediately gave ergot and cleared out the uterine cavity, and took the first opportunity to repair to his study to seek an explanation of this, at that time, to him a strange phenomenon The case was eventually made the subject of a short article which appeared about that time in the *Chicago Medical Examiner*

The lady was anæmic, and made a slow but perfect recovery She has enjoyed good health since, but has never again become pregnant

Dr Henry T Byford had had an opportunity to see this specimen, and it was very much like a bunch of grapes in shape, although Barnes, he believes, claims there is no such resemblance But he bases his views upon the fact that the vesicles are developed from each other instead of from the common stem

In regard to the treatment, he thinks it would now be considered best to scoop out the uterus to prevent septicæmia, and so it would be, if that could be easily done From inquiry of Dr Doering, he understood the opening in the cervix was rather small, the body anteverted, and it would have been necessary to use an instrument in removing the mole He had seen severe inflammation, in the broad ligaments, result from curetting the uterus after abortions, with the dull curette Therefore, he thought it was a point of interest well illustrated in this case, that it is not in every instance the proper thing to do, especially when so much has been passed that there is pretty firm tonic contraction of the uterus

Dr H P Newman I understood Dr Doering to say he used ergot This might explain the fact of finding the cervix closed

Dr Doering I would like to ask Dr Earle whether he discovered any trace of the fœtus

Dr Earle I did not in my case, but there is a specimen in the museum of the College of Physicians and Surgeons in which the fœtus is one and one-half inches long

Dr Charles Caldwell I met with one case in my practice last fall October 10, I was called early in the morning, the messenger informing me his wife was having a miscarriage I found my patient flowing quite profusely She supposed herself five months pregnant, as she had not menstruated since May The last week in July, she flowed slightly for two days The 12th of August, the flow commenced again, and was so profuse that she went to bed and called a physician, who diagnosed her case threatened abortion, and treated her accordingly, keeping her in bed two weeks From that time until the hydatidiform mole was expelled the flow never stopped completely, for a single day, but she passed no pieces of the mole The os was soft and easily dilated I introduced two fingers into the uterine cavity and removed its entire contents The mass was too large to be removed intact, and the os was not sufficiently dilated As I removed each piece the uterus contracted well and firmly, diminishing the size of its cavity rapidly, so I was sure when it was empty

The lochial discharge kept up for three days She remained in bed one day, but the next morning prepared her husband's breakfast, and has attended to her household duties since There were no symptoms of septicæmia following The broken mass would have filled a two quart measure Some of the cysts were as large as a bean I gave Dr Jaggard a specimen to show to his class No fœtus could be found in the mass Small doses of ergot were given for a few days Menstruation was established in December, and the patient is now strong and healthy

The inaugural thesis of Dr F E Waxham, (Chicago Medical College, 1878), entitled

"INTUBATION OF THE LARYNX, WITH HISTORY OF CASES,"

was read by Dr Edward Warren Sawyer

Dr Waxham described Dr O'Dwyer's method of intubation of the larynx, narrated the histories of seventeen cases, in which the method had been employed, and drew the following conclusions

"Intubation of the larynx possesses many advantages over tracheotomy

"1 No opposition is met with on the part of parents and friends, quite a contrast to the difficulty with which we usually meet in obtaining the consent to tracheotomy

"2 It relieves the urgent dyspnœa as promptly and as effectually as tracheotomy, and if the child dies there is no regret that the operation was performed, and no discredit is attached to the physician

"3 There is less irritation from the laryngeal tube than from the tracheal canula As the tube is considerably smaller than the trachea, it does not press upon it firmly at any portion excepting at the chink of the glottis

"4 Expectoration occurs more readily than through the tracheal tube

"5 As the tube terminates in the throat, the air that enters the lungs is warm and moist from its course through the upper air passages, and there is less danger of pneumonia

"6 It is a bloodless operation

"7 It is more quickly performed and with less danger

"8 There is no open wound that may be the source of constitutional infection

"9 Convalescence is more rapid, as there is no ghastly wound to heal by slow granulations

"10 The patient does not require the unremitting care of the physician, as in tracheotomy

"11 I believe it to be a more successful method of treating croup, either diphtheritic or membranous, than tracheotomy

"The only objection to the operation of intubation is the difficulty of its performance"

Dr Christian Fenger said that this was a subject of exceeding interest, and deserves great attention Tracheotomy was one of the few operations that always made him nervous That this operation is attended with some danger there is no question There is danger from hæmorrhage during and after the operation, and there is some danger of shock, which, in cases where there is no membranous laryngitis, sometimes can be traced only to the operation. For instance, he years ago went to make an examination of an old man who had swallowed a little fish bone, that had got into the mucous membrane in the entrance to the larynx, during dinner. Œdema of the glottis necessitated tracheotomy, which was performed without an anæsthetic. There was no hæmorrhage, the dyspnœa was relieved, but the man died about twenty-fours afterwards from the shock and disturbance attributable only and alone to the operation. In other cases hæmorrhage, even under great care in the operation, cannot always be avoided. He has had two cases of such hæmorrhage where the patients have died, one in two hours and another in five hours subsequent to the operation, not on account of the amount of hæmorrhage, but on account of the disturbance in the lungs, caused by a moderate amount of aspirated blood. So, if it is possible to get around the tracheotomy in some other way, then he for one would embrace it with the greatest of pleasure. However, when he saw Dr. Waxham's intubation—which he looked forward to with great interest—he was afraid of the tubes slipping into the air passages, so that the operator could not get hold of them again. That is one thing, and another that came into his mind was the small calibre of the opening in the tubes. He had an opportunity to see a little child that he operated upon where the operation was easy, and relief was instant, and that is all he has seen as yet of the matter. Then, of course, he read the paper. There is one thing that he would be rather afraid of,—but that is a theoretical objection only,—that is, to leave the child without taking the tube out. It seems from the cases reported, however, that in those cases there has never been much trouble of this kind, and theory of any kind is of no value whatever compared with facts.

He believes that this matter is very worthy of careful consideration, but, on the other hand, not until a larger number of cases have been tried will we be able to form any definite opinion about it. But we know enough from the cases recorded here to be desirous of having this new matter tried.

Dr. F. E. Waxham was then elected Fellow of the Society.

FOREIGN CORRESPONDENCE

LETTER FROM NAPLES

(FROM AN OCCASIONAL CORRESPONDENT.)

The Hospitals and Clinics of Naples—The Medical Students—The Cost of Medical Education—Operations in the Hospitals—Systems of Medicine—Development of Blood Crystals—The Cholera Bacillus—Neapolitan Medical Men.

Medically and surgically Naples is in many respects very interesting to a physician. She has hospital capacity for from 3500 to 4000 patients divided into 14 different hospitals, besides the greatest abundance and variety of clinics supplied from a population of city and suburban villas of near 800,000 souls. Her hospitals are not to be commended for beauty of architecture nor for convenience and well ordered appointments internally, but for room I have seen nothing in America or Europe equal to them. There are medical students here from all parts of the world, many of them being able to speak several languages. This is really by position, one of the best centres in the world, and should command a very high position in point of education as well as commerce. There are over 300 professors in the university, and the medical faculty represents the very best of professional talent and experience. I am informed that students pay 40 francs ($8.00) each year to the government for tuition, and, at the end of 6 years, 20 francs additional for tickets of examination and graduation—the professors being employed at stated salaries by the government. A group of students with a professor lecturing to them, all with their hats on, seated on benches arranged in a square in the wards among the patients, is to be seen almost every morning. Separate lecture rooms, however, are furnished for teaching the scientific branches.

With few exceptions, operations are performed in the wards, and on a bed (instead of a table), drawn out in the middle of the room. This is, of course, very awkward and embarrassing to the patient, who sees and hears everything about the preparation for the operation, and in a Listerian consideration of antisepsis is not commendable. Although antiseptic treatment is recognized and seems to be appreciated, in application it is not at all understood. To give an instance. Dr. Dattelo, one of the finest operators I ever saw handle a knife, refused to operate for osteo sarcoma on a little boy unless a separate room was furnished. This was granted after several days, and I was very kindly invited to see the operation. In the middle of a room 12x18 is a rickety single, low bed (no operating table) with linen coarse and soiled, holding a little 8 year old boy with an ugly tumor on the left temple extending forwards and into the external canthus of the left eye. Terrified at the approach of 10 or 12 students, professors, and nurses, he began to cry—opening out instruments and putting on white aprons only added to the child's fears and agony. Ether was finally brought and administered by force out of a kind of reticule or bag, the surgeon being compelled to perform the operation in an uncomfortably stooping position, the bed and clothing receiving the blood not taken up by sponges. The ceiling of the room was badly soiled by leakage and plenty of dirt lay, half swept in the corners, and on the window sill. I thought it a pity for the patient, and that the science, and the results of a skilful operation should thus be jeopardized. Two days after, however, the patient was doing well with no evil signs about the wound.

From what I could learn in practice a disposition to adhere to systems prevails to a much greater extent than obtains in America. It is not only the Neapolitan system, the Milan plan or the School of Pavia, but it is a system of a celebrity. For example, injections hypodermically of corrosive sublimate, for so many days, followed by unction with Neapolitan mercurial salve with sulphate of quinine internally, seems to be the beau ideal Neapolitan system of treating syphilis under all circumstances Titles are not so important anywhere as in England The steward even of the hospital would seem indignant if you said doctor or surgeon Lester, instead of saying "Sir Joseph"—indeed, American independence of thought, action, and manners even in medicine can find no prototype on this side of the Atlantic, but less attention in Naples than anywhere else seems to be given to titles Doctor or professor is enough here for all practical purposes Dr Fienga is *the* microscopist, author of a work on physiology, and several monographs on various subjects He has a very extensive cabinet of microscopical specimens, physiological and pathological, prepared by himself To the German (Teichman) method of developing the crystal "emina" of blood by adding salt and acetic acid and heat to the boiling point, he adds Canada balsam and turpentine, and thus makes the test more delicate, bringing out the characteristic crystal from a much smaller stain of blood The boiling point is very simply obtained by holding the plate over the blaze of a spirit lamp until the drop of prepared fluid between the glass plates becomes white, like steam The doctor very kindly showed me the process, using material from a stain said to be 14 years old He says one can study in two hours all that is to be learned microscopically of the cholera germs, and he showed me various specimens of the microbe in its different states of development taken from various parts of the body, and from the alvine discharges The doctor is an enthusiastic investigator and a hard worker, as is also Dr Scibbelli—the latter having for his specialty, obstetrics and the morbid anatomy of the pelvis He also has one of the most extensive private museums of specimens I have seen

Dr Novo is professor of gynæcology, and a noted author He, Scibbelli, and Fienga presented me with copies of their writings, and I leave Naples with the kindest feelings towards the doctors I shall ever feel under obligations to Dr Conic for his almost undivided attention He is a worthy young man of much promise—the more so, because he soon moves to the Western States of America, where he will have room to spread himself To straighten the leg of an asteoplastic knee-joint in Edinburgh, they divided the patella and removed a v-shaped section of the joint, and reunited the patella by wire Dr Lester (Sir Joseph) of London, removed entire the patella, and in Naples they use Rizzoli's lever screw instrument which tears assunder the plastic bones For the removal of stone, they also use here Rizzoli's lithotrotome, which, they claim, reduces the operation to a child's play of 42 seconds' time In the pathological section of the University Museum here, may be seen real one eyed Cyclopian monsters, and in the National Museum are surgical instruments taken from the ruins of Pompeii, speculums, catheters, forceps, scalpels, etc , just like ours of this age

LETTER FROM VIENNA

(FROM OUR OWN CORRESPONDENT)

Mortality from Puerperal Fever Before and Since Antisepsis—Parametritis and Perimetritis—The International Medical Congress

In a recent letter I reviewed the practice of the Vienna school in relation to puerperal fever I wish now to give some statistics of mortality before and after the introduction of antiseptic precautions

Paris—1829—Maternité—Confinements, 2788 Mortality 252
1831 ‘ 2907 ‘ 254
Vienna—1823—During the epidemic of puerperal fever in February March and April of this year there were 698 confinements of which 133 died
1842—There were 3287 confinements with 518 deaths
1846—4010 confinements with 459 deaths

In May, 1847, Semmelweise published the results of his investigations, and urged upon Prof Klein, in whose clinic he acted as first assistant, the necessity of washing the hands in chlorine water before examining lying-in women Prof Klein laughed at his assistant, but gave the order Semmelweise's paper was badly received, and he himself was regarded as a medical crank See the results

1846	Confinements	3352	Deaths	459
1847	–	3275		176
1848		3556	‘	45
1849		3858	‘	103

This was the year in which Semmelweise was sent away, and his precautions were not observed In 1854, 4,393 confinements, 40 deaths During this year, these details were enforced The statistics of Prag are still more remarkable From 1865 to 1874 the old building was used, which was entirely unfit for purposes of hygienic detail, and the mortality was 6 67 per cent , as follows

Year	Births	Deaths	Per cent.
1865	2576	239	9 28
1866	2673	125	4 68
1867	2368	115	4 98
1868	2712	245	9 04
1869	2505	291	11 62
1870	2249	96	4 27
1871	2329	72	3 08
1872	2210	115	7 01
1873	2189	168	7 67
1874	2346	102	4 35

At this time the new building was completed, and the mortality fell to 0 65 per cent , as follows

Year	Births	Deaths	Per cent
1875	2180	60	2 75
1876	2627	30	1 14
1877	2704	34	1 26
1878	2776	45	1 68
1879	3010	11	0 36
1880	2813	13	0 46
1881	2927	7	0 24
1882	2963	7	0 24
1883	2900	7	0 24
1884	2886	7	0 24

These figures must convince any thinking man not only of the value of absolute cleanliness in obstetrical practice, but of the importance and necessity of antisepsis as I have previously described it Not the excessive practice of some eminent practitioners, that would enforce uterine and vaginal irrigation of an antiseptic fluid, even in cases of normal labor—but the elaborate cleansing of arms, hands and nails, before an examination is made, attention to attire, so that the obstetrician should not wear in the lying-in room the same coat which has followed him in his many daily calls The practice of this school speaks volumes, and meets, for so it seems to me, every indication of exactness without being meddlesome When one compares the low rate of mortality with the indiscriminate examinations made by students and visitors, and bears in mind the unsuitable condition of the building in which both Professors Braun and Spaeth have their material, the results are simply marvellous It proves that antiseptic obstetrics, under the most unfavorable conditions, is infinitely preferable to any other form of obstetrics, even coupled though it may be with every hygienic detail of excellence in the building itself

Parametritis and Perimetritis —I long held with Emmet that the distinction between these two inflammatory conditions was really without any difference, and that clinically they could not be differentiated For sixteen months I have labored faithfully in this direction, both in Berlin and in Vienna, and have availed myself of enormous material and of every other possible means to enter intelligently into the nice discrimination made by German gynecologists To this end I made a close study of the connective tissue of the female pelvis, without a thorough knowledge of which no gynecologist can ever hope for a logical conception of para- or perimetric inflammation To those wishing to make similar investigations I cordially commend Freund's "Gynakologische Klinik," Strassburg, 1885, as being the most exhaustive and thorough work that I know of I am gradually being convinced, by actual observation and constant study, that Emmet's statement is too absolute, and that in many cases the two diseases are entirely separable This becomes more plain to me as I advance more logically in an anatomical survey of the para- and perimetric tissues I do not disguise the fact that even here in Germany, in the polyclinics, the mistake is often made of confounding the two, and that the nice differential points insisted upon by Freund are often lost sight of, and I also realize that in some cases it is really impossible to separate the two, but I do believe, and that thoroughly, that there are other and many cases in which it is not difficult to make the diagnosis At least seventy five per cent or more of all the women that I have examined in Berlin and Vienna, have suffered from acute or chronic inflammations of this sort, and without any exaggeration I think I may safely say that I have seen in the neighborhood of a thousand such cases This will savor less of Munchausen to those who have studied in these schools, and who remember that in Vienna alone, in two touch courses per day, one may examine from twenty-five to forty-five women I have learned to count largely upon the salient characteristics of subjective as well as of objective symptoms In the large majority of instances —nay, more, according to the anatomy of the parts, it *must* be so that in every instance where the symptoms are relegated to a point just behind the cervix, where the connective tissue is situate around the *infra-vaginal* portion, the disease is a "posterior parametritis," but where the tenderness and objective symptoms are higher up in the fornix, where the peritoneum dips down, we have to do with a "perimetritis" In the former instances only the infra or middle cervix will be fixed—partially or wholly—in the latter, the fundus itself will suffer Just so we may have a para cystitis, or a para-kolpitis, or a para proktitis In the connective tissue itself the points of exudation may be limited, they may not run into each other, they may not reach the peritoneum, and they may be absorbed rapidly Perimetritic exudations are situate higher up than those of the parometrium, and are attended with an entirely different symptomatology The *fornix vaginæ* is not flattened out in perimetritis, as it is in parametritis Perimetritic exudates are generally situated high up in the posterior cul de sac, as one would expect to be the case The *collum uteri* is fixed in parametritis, and in endeavoring to move it the patient will complain of pain, which is not the case in perimetritis In short, there are many points of difference between the two, which have been made equally plain to some other gentlemen who have been associated with me in gynecological studies abroad One must see and study both forms, at every stage of development, and must examine by rectum and vagina Examine especially the base of the broad ligaments and the cul de sac of Douglas, also the left lateral fornix (which is a favorite habitat of perimetritis) It took me many months before I learned exactly where to place the inflammation, but the knowledge came with experience, and from a thorough comprehension of just what is meant by pelvic connective tissue

I hear of many medical men in Berlin and Vienna who intend coming to the Congress A R B

DOMESTIC CORRESPONDENCE

INTRIGUE IN THE ASSOCIATION!

TO THE EDITOR OF THE JOURNAL

Dear Sir —The following extract is taken from the *Nashville Journal of Medicine and Surgery*, of February, 1886, and reprinted in the *Medical News*, of February 27

"Of late years this Association has appeared to degenerate into a body merely medico-political, and it is time something should be done to elevate it to a proper standard and make it what the British Medical Association is to the profession in England, representative and national Political intrigue and trickery have too long held sway in this Association and it is time the profession should see to it that it be no longer thus degraded, and be brought back to the place it occupied in its palmiest days From year to year the meetings have become less and less important in a scientific point of view, and it is time every true physician should individually strive to change its downward course If some change is not soon effected, the Association will cease to exist and the profession will turn its attention to the separate special Associations which are all now in a flourishing condition We hope, therefore, that all who can will make an effort to attend the coming meeting "

If the editor who made this statement had looked over the list of names that have figured largely in the meetings of the American Medical Association within the past few years, of whom I need mention only those of Drs Marion Sims and Samuel D Gross, he certainly could not have had the effrontery to parade such nonsense before an intelligent profession The founders of the American Medical Association have conferred a lasting benefit upon the American Medical profession, but during the last few months its enemies have made every effort to destroy its usefulness Doubtless an effort will be made at the coming meeting in May to degenerate the Association into a medico political meeting by the very men who have so roundly abused it, but it is to be hoped that the better element which has hitherto guided its counsels will succeed in preventing the disaffected element of the profession from impairing the usefulness of the Association Its influence for good has been felt from the St Lawrence River to the Gulf of Mexico, from the Atlantic to the Pacific Ocean, and the man whose spleen finds vent in the above quotation is, in the opinion of the writer, an enemy to the medical profession I am, etc ,

Tecumseh, Mich , March 1, 1886

A NAVAL INEBRIATE ASYLUM

TO THE EDITOR OF THE JOURNAL

Dear Sir —I am much struck by Dr Frederick Horner's paper, "A Plea in Behalf of a Hospital for Naval Inebriates," in THE JOURNAL for March 6 It is especially painful to infer that the sober men are inferior to the bulk of their comrades, for we are told that "apart from inebriety, these are in all respects the best and most intelligent men in the service" In every rural community there is a drunken medical practitioner who is "the best doctor in town, if you can find him sober!"

We may grant that inebriety *is* a disease, but it is one the causation of which is so well known that its victims are as inexcusable as those of syphilis Let the cadet and midshipman know that prompt dismissal will follow the first detection of the drinking habit, and there will be no occasion either to cashier or send to an inebriate asylum a valuable and experienced officer at a later date Let the Navy cease to be a school of inebriety, and spare the nation the disgrace of a Naval Inebriate Asylum Teetotally yours,

IRVING W SMITH

Charles City, Iowa, March 10, 1886

NECROLOGY

AUSTIN FLINT, SR , M D , LL D

At a special meeting of the Executive Committee of the New York County Medical Association, the following was unanimously adopted

Whereas, It has pleased God to remove from our Association our beloved and highly honored friend, Professor Austin Flint, M D , LL D , one of our Founders, and an ever willing co worker We desire to record the great appreciation of our loss

Professor Flint, from early manhood, has ever been an indefatigable laborer in the field of Medical Science, and for half a century has been one of the most accomplished teachers and writers in the profession

His varied experience, extending over different portions of our country, enabled him on his settling in New York City, at once to take the foremost place in the profession As a consultant, he was without a peer, his calm judgment, urbane manners, and strict conscientiousness made his presence ever welcome to his brethren As a gentleman, he will be held in grateful remembrance by all with whom he came in contact, his charities were proverbial

His death will be the cause of universal sorrow, especially occurring at a time when his deliberate counsels are most needed We can never forget that genial countenance, those cheerful words, and that buoyant disposition, which, amid the greatest of sorrows, always pointed out the ray of light affording hope.

Therefore, in testimony of your respect for the deceased, it is earnestly hoped that you will attend the funeral services at Christ Church, corner of 35th street and Fifth avenue, on Tuesday, March 16, 1886, at 2 o'clock P M

The members of the Association will assemble in the Sunday School room, entrance on 35th street, at 1 45 P M

CHARLES A LEALE, M D ,
President

GLOVER C ARNOLD, M D , *Sec'y*

A review of the life and work of Dr Flint will appear in the next issue of THE JOURNAL

ASSOCIATION ITEMS.

AMERICAN MEDICAL ASSOCIATION

The Thirty-seventh Annual Session will be held in St Louis, Mo , on Tuesday, Wednesday, Thursday and Friday, May 4, 5, 6 and 7, commencing on Tuesday at 11 A M

The delegates shall receive their appointment from permanently organized State Medical Societies and such County and District Medical Societies *as are recognized by representation in their respective State Societies*, and from the Medical Department of the Army and Navy, and the Marine Hospital Service of the United States

Each State, County, and District Medical Society entitled to representation shall have the privilege of sending to the Association one delegate for every ten of its regular resident members, and one for every additional fraction of more than half that number *Provided*, however, that the number of delegates for any particular State, territory, county, city or town shall not exceed the ratio of one in ten of the resident physicians who may have signed the Code of Ethics of the Association

Secretaries of Medical Societies, as above designated, are earnestly requested to forward, *at once*, lists of their delegates

Also, that the Permanent Secretary may be enabled to erase from the roll the names of those who have forfeited their membership, the Secretaries *are, by* *special resolution*, requested to send to him, annually, a corrected list of the membership of their respective Societies

SECTIONS

"The Chairman of the several Sections shall prepare and read, in the general sessions of the Association, papers on the advances and discoveries of the past year in the branches of science included in their respective Sections "—*By Laws*, Article 11, Sec 4

Practice of Medicine, Materia, Medica and Physiology —Dr J T Whittaker, Cincinnati, Ohio, *Chairman*, Dr B L Coleman, Lexington, Ky , *Secretary*

Obstetrics and Diseases of Women and Children —Dr S C Gordon, Portland, Me , *Chairman*, Dr J F Y Paine, Galveston, Texas, *Secretary*

Surgery and Anatomy —Dr Nicholas Senn, Milwaukee, Wis , *Chairman*, Dr H H Mudd, St Louis, Mo , *Secretary*

State Medicine —Dr John H Rauch, Springfield, Ill , *Chairman*, Dr F E Daniel, Austin, Texas, *Secretary*

Ophthalmology, Otology, Laryngology —Dr Eugene Smith, Detroit, Mich , *Chairman*, Dr J F Fulton, St Paul, Minn , *Secretary*

Diseases of Children —Dr W D Haggard, Nashville, Tenn , *Chairman*, Dr W B Lawrence, Batesville, Ark , *Secretary*

Oral and Dental Surgery —Dr John S Marshall, Chicago, Ill , *Chairman*, Dr A E Baldwin, Chicago, Ill , *Secretary*

A member desiring to read a paper before a Section should forward the paper, or its *title* and *length* (not to exceed twenty minutes in reading), to the Chairman of the Committee of Arrangements, at least one month before the meeting —*By-Laws*

Committee of Arrangements —Dr Le Grand Atwood, St Louis, Missouri, *Chairman*

AMENDMENTS TO BY-LAWS

By Dr Foster Pratt, Mich —Each Section shall nominate its Chairman and Secretary—all other nominations to be made, as now, by the nominating Committee

By Dr I N Quimby, N J—Create a new Section, to be known as the Section on Medical Jurisprudence

WM B ATKINSON, M D ,
Permanent Secretary

1400 Pine St , S W cor Broad, Philadelphia

MISCELLANEOUS

DR GASPER GRISWOLD, one of the most promising young physicians of New York, died on March 4, after a short illness He was a member of the editorial staff of the *New York Medical Journal*

PHOTOGRAPHIC DIAGNOSIS —Henry de Parville, in "Le Gagne-Petit," tells of a case in which the sensitive plate for a photograph showed some very peculiar dark specks When the sitting was made the subject had peculiar sensations of the skin, but nothing was visible Two days after the sensitive plate announced that something was wrong the woman was taken sick with an eruptive fever

UNCONSTITUTIONAL BOARDS OF HEALTH IN NEW JERSEY —The New Jersey Supreme Court has declared a law to be unconstitutional under which certain boards of health were organized and operated The boards so affected are abolished, among them the Board of Health of Camden, which has now no sanitary protection except that afforded by the sanitary committee of the common council

A MILK STANDARD —The Court of Appeals of New York has just decided that the legislature has the power, in an act forbidding the sale of impure or adulterated milk, to fix a standard by which it shall be judged, not only as a rule of evidence but as an explanation of the meaning of the words used in the Statute

POISONOUS WALL-PAPERS IN MASSACHUSETTS —A second hearing in regard to legislation to prevent the sale of wall papers containing poisonous ingredients was recently held before the Committee on Public Health of Massachusetts Many leading chemists appeared in support of the measure

NOTE BOOK FOR OVARIAN AND ABDOMINAL TUMORS —We have received from the publishers, Cupples, Upham & Co , of Boston, a convenient note book for cases of Ovarian and other Abdominal tumors, arranged by Dr John Homans

NEW YORK STATE MEDICAL ASSOCIATION, FIFTH DISTRICT BRANCH —The third special meeting of the Fifth District Branch will be held in the Common Council Chamber, Yonkers, at 2 P M on Tuesday, March 23, 1866 The following papers are promised

"The Physician and the Pharmacist—their Relative Duties," by J P Garrish, M D

"A Case of Meningeal Extravasation with Curious Localization of Nerve Symptoms," by A L Carroll, M D

"Sacculation and Perforation of the Bladder as Consequences of Chronic Retention of Urine," by J W S Gouley, M D

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U S NAVY DURING THE WEEK ENDING MARCH 13 1886

Woods, George W , Surgeon, ordered to Navy Yard, Mare Island, to relieve Surgeon W K Scofield April 1

Scofield W K , Surgeon, detached from Navy Yard, Mare Island, and wait orders

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U S MARINE HOSPITAL SERVICE FOR THE THREE WEEKS ENDED MARCH 13 1886

Benson, J A , Passed Asst Surgeon, resignation accepted, to take effect April 6, 1886, and leave of absence granted until that time March 10, 1886

THE MECHANISM OF INDIRECT FRACTURES OF THE SKULL[1]

BY CHARLES W DULLES, M D,
SURGEON TO THE OUTPATIENT DEPARTMENT OF THE HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA AND OF THE PRESBYTERIAN HOSPITAL IN PHILADELPHIA

Hippocrates gives the earliest definition of the fractures we are about to study The bone is broken in another part of the head than that in which the man received the injury, and the bone was stripped of the flesh This definition remained unimproved until more than two thousand years later, when in 1873, Félizet suggested the division of fractures of the cranium into "immediate and mediate," if, indeed, this suggestion be an improvement Hippocrates despaired of the cure of fractures remote from the seat of the wound, and seems to have had no more definite idea about them than that they might occur The next author, Celsus, says It sometimes happens, also, that the blow has fallen upon one point, and the bone is cleft in another He furthermore recommends cutting down upon any point where there is softening and swelling, in case no fissure is found at the point struck, and bad symptoms arise Here is a decided advance upon the teaching of Hippocrates, another being the observation of Celsus that the vessels of the brain might be ruptured without fracture of the cranium, anticipating a much later explanation of the term "*contrecoup*"

The Royal Academy of Surgery of Paris proposed in 1760, and again in 1765, as the subject for a prize, the following proposition "To establish the theory of counterstroke in lesions of the head, and the practical conclusions which may be drawn from it" On the first of these occasions the prize was not awarded, on the second, it was awarded to Grima, who sent in for the second time the same essay which he had sent in for the competition, and which had been thought the best at that time The same question was proposed for the prize of 1768, when prizes were awarded to Saucerotte and Sabouraut, for which Chopart also presented an essay, which was accepted and published by the Academy Chopart not only recognized the elasticity of the skull, but exaggerated it and, as a diagram in his essay shows, believed that a blow produced alternating and reciprocal shortening and lengthening of the axes, in a manner which some authors describe as undulatory Nor would the history of this epoch be complete without mention of a valuable memoir upon counterstroke in other parts of the head, written by David, though published under the name of his pupil, Bazille—to which a double prize was awarded in 1771

In 1844, Aran published an exceedingly valuable paper on fractures of the base of the skull, in which he formulated a theory which has been known by his name ever since This theory was, that fractures of the base are always connected with fractures of the vault, from which they radiate, following a line within the zone in which the former occurred, and taking a course which corresponds with shortest route to the base His conclusions are formulated as follows

1 He never saw a fracture of the base, caused by a blow without a direct fracture
2 Fractures of the vault joined the base by "irradiation," and crossed any sutures in their way
3 They followed the shortest route to the base (the curve of shortest radius)
4 They were ordinarily limited to certain regions (corresponding to the several great fossæ of the cranium), and followed a certain direction
5 Fractures of the vault sometimes coincide with *independent* fractures of the base, but only when there is considerable comminution (*ebranlement*) and very multiplied fractures

In 1847, Guthrie published a monograph on injuries of the head, in which he gives an excellent *resume* of the history of various sorts of fractures of the cranium Among them he speaks of counterstroke, the occurrence of which from temporal to temporal, or from parietal to parietal, he doubts, but says that fracture of the base from blows on the vertex or occiput are among the commonest accidents of surgery

In 1853 was published, in *Guy's Hospital Reports*, a first instalment of Mr Hilton's sagacious lectures on the cranium, which was followed, in 1855, by their publication entire in a separate volume, by Dr Pavy, after their revision by Mr Hilton himself In these lectures Mr Hilton explains fractures of the skull upon the "vibration theory," and speaks of the posterior clinoid processes and the extremities of the petrous bone as points to which vibrations are conducted, and where they are transmitted to the cerebro spinal fluid, thus being "interrupted or lost before reaching the cerebral tissues," etc The fallacy of this conclusion I shall have to consider hereafter

---

[1] Abstract of a paper read before the College of Physicians of Philadelphia on February 3 1886

In 1854 the keynote to a new theory of indirect fractures of the skull—which had, however, as we have seen, been foreshadowed much earlier by certain observers—was struck in Germany by experiments made by Bruns, of Tubingen, to determine the elasticity of the cranium.

In 1864, Chauvel published a thesis on fractures of the cranium, founded upon a careful study of its anatomy, in which he laid great stress upon the elasticity of the skull, and described the "vibrations" produced by a blow, as the repeated and alternating shortening of the prime axis and lengthening of the transverse axis. He called attention to the fact that the petrous bone, although the hardest in the cranium, is the one most frequently fractured. He described three kinds of fracture: 1, direct; 2, contra direct; 3, indirect. The first kind is simple enough. The second occurs opposite to the point struck, and he offered no explanation of them, except the comparison of those caused by the spinal column to the manner in which the handle is driven into the head of a hammer by striking the remote end of the handle against some resisting body. The third form of fracture he defined as that occurring between the point struck and that directly opposite. This he found in eleven out of sixty fractures.

In 1872, Schwartz analysed 115 cases, in most of which the history was very incomplete, and he found fracture of the base alone, without fissure of the convexity, only seven times. He found about thirty-nine per cent of the fractures limited to the zones described by Aran and Hewett, while in over sixty per cent this regularity was wanting. This is one of the most important features of his investigations. Another is that the study of fractures he had analyzed showed that the petrous bone was fractured in 66 out of 115 cases, and that force applied to the side of the head caused fractures somewhat parallel to the axis of the bone, while force applied to the occiput, or forehead, or vertex, caused fractures transverse to the axis. This was an important contribution to the accumulating material for a new consideration of the mechanism of indirect fractures of the skull, as we shall see hereafter.

In 1873, Felizet published an elaborate illustrated monograph[1] on the subject of fractures of the cranium. He regards this as a solid case, of a spheroidal shape, but claims that its internal configuration renders inaccurate a comparison of it to any geometrical figure whatever. By experiment he demonstrated that the dura mater makes the skull where it is attached more resistant to fractures caused by flattening its curve. Experimenting with a billiard ball let fall from a height, he found that its equator was increased, that this increase was greater in a direction at right angles to its fibres than in a direction parallel to them. The result was an ellipsoidal equator, and when a fracture occurred, this crossed the long diameter at right angles. He unwittingly paraphrases the theory to which I have several times alluded, and which I shall soon consider, in saying, "We know that a fracture results from depression of the curved surface situated between two resisting pieces, and we know, also, that every effort tending to depress this curve divides into two forces, the one a driving force (*force de tassement*), which acts on the axis, or near to it, of the supporting walls; the other, a disruptive force (*force de glissement*), which acts transversely to them, and tends to separate the two extremities of these pieces." He compares the separation of sutures, the result of blows, to that which is effected in anatomical preparations by filling the skull with dry peas and then soaking them, so that by swelling they tear the skull apart. He declares that there is a perfect analogy between this and what he calls the "*grand fracas*" (grand smash), in which he says "the bones, compressed over a large surface, rock (*basculent*), and this rocking movement sets up violently a dragging force perpendicular to the plane of the surface of union of the bones of the cranium." As we shall see hereafter, this is the same as saying that a force which depresses an elastic curved figure, will enlarge its diameter, and be converted into a disruptive force acting at right angles (perpendicular) to the meridian. Herein Félizet comes near to the theory which the Germans call the "Berstungs" (bursting) theory, although he does not quite reach it, and may perhaps, even now, not see his statements to be so strong a confirmation of it as they appear to me to be.

The term "*contrecoup*" Félizet rejects, and would adopt that of M. Beau, of Brest, who called indirect fractures "mediate." Félizet compares the mechanism of these fractures to those produced by a blow upon a wedge or a chisel. The part broken, he holds, is directly struck by another part, which in its turn, received a blow and transmitted it. Yet he admits that, very rarely, these fractures by *contrecoup* do occur. He divides fractures of the cranium into direct, indirect, and mixed. Indirect fractures include those which are independent. In respect to the application of the violence which causes them, fractures may be divided into immediate and mediate. His conclusions may be briefly stated as follows: all fractures not immediately limited to the point of impact follow certain definite routes, to which they are restricted by the added strength of certain parts of the skull, which depends upon the presence of certain "*murs boutants*" (buttresses): the petrous bones, the orbito sphenoid prominences, the occipital protuberance, and the naso frontal protuberance. The basilar process and the antero lateral parts of the occipital bone remain intact amid all fissures and constitute a "centre of resistance." The vibration theory, he says, is disproved by experiments, the fundamental phenomenon is a violent flattening of part of the vault, and a separation of the resisting portions (*pieces de resistance*) which support it. When the violence is perpendicular to the surface of the cranium, fractures radiate directly to the base. In this, it will be seen, Felizet agrees with Aran. Finally, he admits that these are fractures, called by "*contrecoup*," the mechanism of which escapes us completely.

The opinions of Félizet are founded upon a careful analysis of a number of pathological specimens and upon a number of experiments upon fresh skulls

[1] Félizet, G. Recherches anatomiques et expérimentales sur les Fractures du Crâne. 8vo. Pp. 167. Paris, 1873.

The value of his work can be appreciated only after a thorough study of it The result of it was to bring him to a conclusion which may be succinctly stated as that indirect fractures are due to a disruption by splitting There can be no doubt that the course of a fracture will be determined to a considerable extent by the reinforcements which the skull has, in certain places, from its buttresses (*murs boutants*), but, as we shall see hereafter, these very buttresses are often broken both transversely and longitudinally, and Félizet's centre of resistance is by no means a centre of immunity, but an exceeding frequent seat of fracture

A few years later Baum[1] opposed the vibration theory, and made some experiments by strewing sand on a skull and applying a vibrating tuning fork to it From these experiments he concluded that vibrations were restricted by surrounding less elastic parts, like the vibrations of a drum head The petrous bone, however, he concluded, owing to its anatomical structure and relations, vibrates like a rod held by one end in a vise He refers to Weber's wave theory, and concludes that blows upon the skull do not furnish the conditions of repeated impulses which produce a high vibratory action By compression of a few skulls in a suitable frame he got results which correspond to those of later German experimenters who adopted the "bursting" theory

In 1878, P Bruns attributed indirect fractures to the elasticity of the skull, as described by von Bruns in 1854, and explained the frequent occurrence of these fractures in the base of the skull by the fact that this is the weakest and most fragile part of it In the same year, Perrin made some very instructive experiments, in which he attempted to imitate the usual conditions of the skull by protecting it with an elastic cushion of cotton wadding or of caoutchouc and then throwing it upon a stone pavement, or by putting his cushion on the pavement itself He always got direct fractures by blows, and by precipitating the skull he usually got indirect fractures He showed typical specimens to the Societe de Chirurgie, in all of which the fractures were indirect and meridional, and in some interesting cases the vitreous alone was involved in certain places He found that blows on the vertex or occiput usually cause fractures by contrecoup (which he defines as fractures occurring at a place other than that struck), direct fractures being rare exceptions, while blows on the forehead, the parietals, or the temporal bones, rarely cause any but direct fractures

In 1880, Bergmann published another valuable contribution to this subject He compared the elastic conditions of the skull to those of the thorax, which, when compressed or struck in one part, breaks in another He also compares the mechanism of fractures of the skull to the bursting of the eyeball under pressure, referring to Arlt's demonstration, that when compressed the eyeball bursts in the equator Fractures from severe blows, he believes follow this law, those dependent upon moderate force follow the law laid down by Félizet He calls attention to the importance of duly estimating the variations in amount, direction and velocity of the force applied to the skull, and the support afforded by strengthening bones of the skull and face He cites Baum (whom I have cited) as refuting the vibration theory, and seems to have the idea that indirect fractures of the skull are to be attributed to a disruptive force, and not to a propagation of vibrations

In 1880, Messerer conducted a series of experiments which demonstrated more accurately than had ever been done before the elasticity of the cranium, and which made clear the fact that when the skull is compressed in one axis, the circumference at right angles to it is enlarged

In 1881 Nicolai Hermann published an inaugural dissertation on fractures of the base of the skull, in which, besides an analysis of seventy five cases gathered from various sources, he gives an account of seventeen experiments, in which he compressed the skull in longitudinal, transverse, and diagonal directions, until it broke His experiments always resulted in a fracture parallel to the direction of the compressing force He believes that fracture always begins at one of the points compressed and travels away from it By analyzing the cases he had collected he concluded that they supported his deductions from experiments It seems to me that some of his figures show plainly that the fissures must have begun at the middle and travelled both ways In the same year Julius Schranz published an account of thirty four experiments upon skulls, some (thirteen) from which the vault had been removed, but the most of them entire, in which he endeavored to imitate the conditions in which fractures are caused by different sorts of violence The experiments were interesting and instructive The great majority of the fractures he produced were splitting fractures, and *not* immediately connected with the point to which the violence was applied In a considerable number isolated pieces of the vitreous table were split off, or the dorsum ephippii These (and other indirect fractures), he says, can only be explained by the vibration theory A curious result of his experiments was that the brain was injured only once, and the dura mater separated from the bone only three times[1]

But it remained for Von Wahl, in 1883, to utilize the material which had been recently gathering, and to formulate unequivocally the theory that fractures of the skull may be divided into 1, crushing fractures, in which the line of fracture runs at right angles to the axis of the force applied, and 2, bursting fractures, in which the lines of fractures are parallel to the axis of the force which gives rise to them, and which begin, in the words of Messerer, at some point in a line which, like the equator, in relation to the poles of the earth, circumscribes the hollow figure in a plane equally distant from both points of compression He claims that, in compression of the skull—which may be gradual, as in a vise, or sudden, as when effected by a fall or blow—its elasticity, *in toto*, comes into play, and while its diameter which is parallel to the force applied is shortened, its diameters which lie at right angles to this are lengthened. The result is, that indirect fractures run in lines which we may describe as meridional. His conclusions rest not only on theoretical considerations and a review of the testimony and opinions of others, but also upon his own clinical experience, and a series of ingenious experiments, which are fully described and beautifully illustrated in his monograph, a careful study of which may, without injustice, be said to be indispensable to one who would form a direct opinion upon the subject of which it treats.

[1] Baum W Beiträge zur Lehre von den indirecten Schädelfracturen Langenbeck s Archiv f klin chir Bd xix pp 381–399 1876

In 1884, Dr. Nancrede, of this city, published an elaborate and valuable paper on "Injuries of the Head,"[1] in which he adopts the vibration theory, and supports his opinions with some interesting anatomical and physical considerations. He regards the base as a stronger part of the cranium than the vault, speaks of the brain as lying on a water-bed, and describes vibrations of the bones as travelling by the nearest "anatomical" route to the base, there to be discharged, like electricity, at certain points—the ends of the petrous bones and the clinoid processes—into tissues which are non conductors of vibration. He also calls attention to the important influence which the position of the head has upon the direction in which a force applied to the condyles will be conducted. In a very interesting case, which he cites from his own experience, there was a separation of the masto occipital suture, which he says was forced apart "as if from within."

In 1884, Messerer published a second and most admirable paper on fractures of the cranium in which he gives a description and analysis of eighty two experiments on fresh skulls, sometimes on entire cadavers. His experiments included accurately regulated blows upon skulls, detached or resting on the spinal column, and falls of the skull upon a hard base. These experiments completely refute the laws of Aran as well as those of Félizet, and seem to show conclusively that indirect fractures of the skull are dependent upon separation of the meridians caused by the depression produced at the point of contact by a blow.

Finally, our sketch of the history of this subject is brought down to the present year by a reference to the paper of Greder, published in the early part of 1885.[2] The experiments of Greder were made upon skulls connected with the trunk and still covered with their integuments and containing the brain, by blows with a weight of 6400–7650 grammes (about 12–15 pounds). After a large number of these experiments, some of which were most ingeniously varied, Greder comes to the conclusion that solutions of continuity of the base of the skull are to be regarded as the result of bursting, that the direction of fissures is parallel to that of the force causing them, that the extension of a fissure is dependent upon so many intercurrent conditions peculiar to each skull, that it can at most be only suspected from the intensity of violence. As to the point at which the burst begins, he holds that it is not always in the equatorial line, nor always at the point of impact, but at that point where resistance to the disruptive force is least. This will happen, he thinks, in the majority of cases, in the equator or in its neighborhood.

THE ELASTIC PROPERTIES OF THE SKULL

In 1854, von Bruns demonstrated the elastic properties of the skull by a series of experiments which only required multiplication and variation to confirm what an important part the elasticity of the skull plays in the production of indirect fractures. Since then, almost innumerable experiments and studies of specimens of fractures of the skull have cooperated to establish the conviction that, with certain exceptions, the mechanism of indirect fractures of the skull may reasonably be explained according to what the Germans call the "bursting theory," *i. e.*, to the conversion of a direct depressing force into an indirect disruptive force, produced by a shortening of the axis parallel to the direction of the force and a complementary lengthening of the axis at right angles to the former.

The experiments of Messerer can be analyzed so as to throw a great deal of light upon the physical properties of the skull, revealing the parts in which it is strongest, and those in which it is weakest. But, in order to understand their significance, we must have a clear idea of the mechanism by which, in a hollow case, the shape of which has a general resemblance to that of a spheroid or ellipsoid, a compressing force is converted into a disruptive force. It will be readily seen that when an elastic spheroid is compressed in any diameter, all the diameters lying at right angles to this, that is to say, in planes parallel to that of the equator, must be elongated. The experiment of pressing on the convex side of a bow, the ends of which rest on the ground, will illustrate what takes place in every chord of every arc that is depressed. It is equally clear that the elongation of the diameters lying in any plane will elongate the circumference of this plane, because a circumference of longer radius is longer than a circumference of shorter radius. As a result of this elongation of the circumferences parallel to the equator in any spheroid or ellipsoid, the meridians passing from pole to pole will be separated in a direct ratio to the extension of the different diameters and circumferences. This operation is illustrated whenever an umbrella is raised.

As a consequence of the separation of the meridians in a hollow sphere or ellipse, particles which before occupied a certain space between two meridians, will be compelled to separate in order to occupy the increased space between the meridians. The consequence will be that, in every case such as we have supposed there will be a struggle between the cohesion of the particles and the disruptive force due to the separation of the meridians, and whenever the disruptive force overpowers the cohesion of the particles lying along and between two of the meridians, a solution of continuity will take place. The disruptive force will be at a maximum at the equator, but the same conditions of disruptive force opposed to cohesion will be found in different proportions in every line parallel to the equator. As a result, in a perfect sphere with homogeneous walls such a solution of continuity would naturally begin at the geometrical equator and extend equally and simultaneously in opposite directions in a meridional line toward the poles *But in a spheroid or ellipsoid not regular in* shape, and with walls varying in strength in different parts, the result would be modified by these variations This is exactly what we find in the case of the skull, which, while bearing a certain resemblance to an ellipsoid, does so in only a modified way, and can only be expected to exemplify the law just stated subject to modification due to its own peculiarities

[2] Greder, Wilhelm. Experimentelle Untersuchungen über Schädelbasisbrüche. Deutsche Zeitschrift für Chirurgie. Bd. xxi. 5 und 6 Hefte, 9 März, 1885. pp. 491–510. tafeln vii.–xiv.

With this in mind, let us see what the experiments of Messerer show Messerer found that the skull burst in the base under an average pressure 650 kilogrammes applied in a longitudinal direction, and under an average pressure of 520 kilogrammes applied in a transverse direction From this we may draw two very important deductions First, because the burst took place in the base

Corollary I The cohesive power of the base of the skull is less than that of the vault

Second, because the skull burst under a pressure of 529 kilogrammes applied transversely, and under a pressure of 650 kilogrammes applied longitudinally

Corollary II Cohesion is less in the coronal zone of the skull than in the sagittal zone—that is to say, the skull is less able to resist a disruptive force due to blows upon the vertex or sides in the coronal zone than it is to resist a similar force caused by blows applied to the forehead or occiput This is not only a fair inference from the experiments of Messerer, but it also accords with clinical observation

Messerer found again that compression of the skull in a transverse direction, with a force of 520 kilogrammes, diminished the transverse diameter 4 4 millimetres, and that compression in a longitudinal direction, with a force of 650 kilogrammes, diminished the longitudinal diameter only 2 7 millimetres From this we may deduce

Corollary III The skull is more compressible in the transverse diameter than in the longitudinal diameter (This fact tends to strengthen the deduction of Corollary II)

Messerer found, also, that compression of the skull in the transverse diameter, with a force of 520 kilogrammes, increased the longitudinal diameter 0 4 millimetre, and the perpendicular diameter 0 6 millimetre From this we may deduce

Corollary IV The skull is more extensible in the perpendicular diameter than in the longitudinal diameter of the sagittal zone The natural inference from this corollary is that, under the influence of a force applied to the sides of the head a fracture which would naturally begin in some point in the sagittal zone, will begin in that part of it which is intercepted by the perpendicular diameter more readily than in that part of it which is intercepted by the longitudinal diameter—that is to say, at the base or vertex rather than at the forehead or occiput We have already seen (Corollary I) that the cohesion of the skull is less at the base than in the vault, therefore, of the two points just indicated, the base is that of election Here, again, clinical observation supports our deduction

Messerer found, further, that compression of the skull in the longitudinal diameter with a force of 650 kilogrammes increased the transverse diameter 0 6 millimetre, and the perpendicular diameter 0 1 millimetre From this we deduce

Corollary V The skull is more extensible in the transverse diameter than in the perpendicular diameter of the coronal zone (This is the converse of Corollary III) The natural inference from this corollary is that, under the influence of force applied to the forehead or occiput, a fracture which would naturally begin at some point in the coronal zone will begin in that part of it which is intercepted by the transverse diameter more readily than in that part of it which is intercepted by a perpendicular diameter—that is, at the sides rather than at the base or vertex We have already seen (Corollary I) that cohesion is less in the base than in the vault, therefore, a fracture which, for the reasons just stated, would naturally begin at the base of the skull would be more likely to occur near the base than near the vertex In estimating this probability it may also be borne in mind that the horizontal equator of the skull lies nearer to the base than to the vertex, the curvature of the former being much less than that of the latter So that the point of election for the fractures we are now discussing would naturally lie low down on the side of the skull This deduction also is supported by clinical observation

Messerer found, again, that compression of the skull in a transverse diameter, with a force of 520 kilogrammes, increased the longitudinal diameter 0 4 millimetre and the perpendicular diameter 0 6 millimetre, and that compression of the skull in the longitudinal diameter with a force of 650 kilogrammes, increased the transverse diameter 0 6 millimetre and the perpendicular diameter 0 1 millimetre From this we may deduce

Corollary VI The skull is more extensible along the sagittal equator than it is along the coronal equator We have already seen (Corollary III) that the skull is more compressible in the transverse diameter than it is in the longitudinal diameter It is, therefore, seen that the equator along which the skull is more extensible (the sagittal) is that one the plane, of which is cut at right angles by the diameter in which it is more compressible (the transverse), and *vice versa*, which furnishes in the skull a demonstration not only of the elongation of the equator which is produced by depression of the poles of a spheroid, but also of the direct ratio of this elongation to the depression Furthermore, it appears from the observation of Messerer just cited, that a smaller force applied to the skull in a transverse direction will produce a greater elongation of the corresponding equator than will be produced by the application of a decidedly greated force in a longitudinal direction From this we may draw the deduction that force applied to the side of the head is more likely to produce a fracture crossing the sagittal equator than force applied to the forehead or occiput is to cause a fracture crossing the coronal equator This deduction is in accord with the results of Messerer's experiments, in which the skull burst under a pressure of 520 kilogrammes applied in a transverse direction, and only under a force of 650 kilogrammes applied in a longitudinal direction   It is also in accord with clinical observation

We have now analyzed Messerer's experiments so as to ascertain the points of election for disruptive fractures which may occur in (that is, across) two of the principal equators of the skull, the sagittal and coronal   It is not possible to discover in the same way the points of election in the horizontal equator of the skull, for Messerer found that compression of the skull in the vertical direction, between the vertex and the spinal column, led to a direct driving in of the base under so small a pressure as 270 kilogrammes

The results of our analysis of these experiments may be summarized as follows   1 Bursting fractures are more likely to occur at the base of the skull than in the vault   2 Force applied to the side of the head may be expected to produce a bursting fracture crossing the sagittal equator   Such a fracture is more likely to occur in the base than at the vertex   3 Force applied to the forehead or occiput may be expected to produce a bursting fracture crossing the coronal equator   Such a fracture is likely to occur in the temporo-parietal region, and nearer to the base than to the vertex   4 Force applied to the vertex or base of the skull may be expected to produce a fracture at the base [1]

(*To be concluded*)

TUBERCULOSIS PULMONUM, ACUTE AND CHRONIC —ITS NATURE AND TREATMENT

BY A S v MANSFELDE, M D,

OF ASHLAND NEB

PERMANENT SECRETARY, NEBRASKA STATE MEDICAL SOCIETY   PRESIDENT OF THE RAILROAD SURGEONS SOCIETY OF NEBRASKA ETC

(*Concluded from page 313*)

We are now prepared to follow the development as it occurs in the lung, as well as appreciate the conditions which form its clinical picture—and perhaps draw conclusions for the treatment of the disease which approach somewhat nearer the goal striven for—its cure

Grant that the soil for the development of the disease has been furnished in accordance with the requirements above indicated, it is still absolutely necessary that the seed be furnished for the harvest of death—and this is supplied by the bacillus of Koch, the bacillus tuberculosis   The writer is forced by the array of facts upon the one hand, and the absence of one authenticated case of inherited tuberculosis upon the other, to join the army of those who believe that the lesions, *i e*, the anatomical parts of our disease, may and do exist without the presence of the bacillus, but tuberculosis never occurs or exists without the bacillus of Koch

Here it may be well to state (in order to prevent confusion) that the occurrence of tuberculosis in the embryo has been demonstrated, and the author is well aware of the fact, but he also knows that in such cases *the embryo invariably presents the primary lesions in the liver*, the organ with which the mother's blood first comes in contact, *and that the mother is always tuberculous herself,* and the writer has no doubt that in such mothers tubercle bacilli can be detected in the blood   But who has ever heard of a healthy mother, having cohabited with a tuberculous husband, giving birth to a tuberculous child? The bacillus tuberculosis, therefore, is the most important factor in the establishment of the disease, without it tuberculosis is non-existent, however many tubercles may have been formed by the atomization of cheese, flour and other things   We will not stop to dwell on the causes which make the apices of the lungs the favorite seat for tuberculosis, presumably mechanical forces play the greater, if not exclusive rôle in this, of which by far the most important seems the gravitation of the blood in the lung towards the middle and lower lobes   We have already observed that ischæmia is an important adjuvant in the development of this disease   The seed, the bacillus, and in the very nature of things, more often is spores, contained in the form of dust in the air inhaled, finds its way into the lungs, or, more properly speaking, is imbedded upon a spot denuded of its epithelium   (For it must be remembered that normal epithelium offers an insurmountable barrier to the ingress of bacilli, if not of their spores also) Or, what is more frequently the case, the seed is sown upon the contents of the alveoli, or, more definitely stated, the acini of the lung, the food consisting of fibrin, alveolar epithelium and leucocytes, and they grow and multiply, when they are prepared to attack the surfaces denuded of their epithelium, and in this wise

The bacilli find their way into *lymph spaces*, and preferably those connected with the base of the lobulette, or acinus, simply because they are the most abundant in this situation   The advent of the bacillus is the signal for the graphically described " battle of cells with bacteria "   The leucocytes endeavor to eat the intruder (and this must not be considered a fiction, for it has been observed taking place), and if successfully accomplished, as no doubt often happens, the description would end with the death of the hero—but, unfortunately, the bacillus will not only triumph, but in conquering it grows and multiplies   Other leucocytes now endeavor to devour both the bacilli and their victim, and in like manner fall an easy prey to the parasites   Thus quickly a conglomerate of cells (a ball, a tubercle) is formed, the type of the recent tubercle, minus the giant cells   And the absence of the giant cell in these formations is not an accident, but an invariable rule   It is otherwise when the bacillus is attacked (or attacks?) by the aforementioned endothelial cells of the lymph spaces, or the amœboid cells of the fibrous tissue   Here a somewhat different manœuvre ensues   The bacillus finds its way into the cell, or is taken up by the cell, we do not know which, and now, by the emanation from its economy of a poison of the nature of ptomaines (D L Brieger), or by the supply of a ferment (capable of being furnished by all albuminoid

---

[1] It may be worth while to call attention to the fact that there is no essential difference between a blow applied directly upon the vault or side of the skull and one transmitted through the spinal column by a fall upon the feet or buttocks

substances of cells), the part of the cell *on* which, or *in* which the bacillus is lodged necroses by a typical coagulation of its substance (Prof C Weigert) That this is true necrosis, namely the partial coagulation, is evident from the fact that the nucleus not only remains alive, but its adherent protoplasm accumulates and furnishes the means for the segmentation of the nucleus, but whilst this occurs in the one cell, another, and more often many cells, not only pass through the same changes, but adhere, as would be expected, to the *necrosed* part of the first cell so affected, thus forming a plexus of a very peculiar form, *i e*, centrally a mass of necrosed tissue, surrounded with the living protoplasm of cells, which contains one or more nuclei, of course peripherally placed, like rosettes or wreaths, when the whole conglomerate is considered, this is the typical *giant cell* of Langhans

And just as in the tuberculous ulcer the bacilli occupy the ground between dead and living tissue, so here we find in the giant cell, the bacilli between the necrosed central portion and the periphally placed nuclei, which, as is known, always disappear when the cell has become the victim of the coagulation necrosis In fact, even the bacilli are lost to view in this dead part of the growth, having, as some writers assume, suffered destruction, only with this difference, that they have left their progeny, the spores, behind (which has not yet been demonstrated by staining media), to serve in their turn the purposes of a renewed invasion of the adjacent tissue Exterior to this conglomerate of cells, whether composed of leucocytes only, or of giant cells and leucocytes, the consequences of an irritation of the tissue always appear in the form of an invasion of multiplying tissue cells and wandered-in white blood corpuscles, to give rise to the attempt at organization most always noted upon the periphery of slowly forming tubercles and masses of tubercles And this attempt at organization succeeds in the ratio of the blood supply to the parts, and their own normal constitution, and fails as the parts approach the composition described by Formad, and known as the scrofulous If it succeeds, then the wall of cicatricial tissue built around the tubercle prevents the invasion of the surrounding tissues by its contents, the spores of bacilli particularly, after they have been set free by the softening of the tubercle And this holds good not only for the single tubercle, but also for any number of them, and, indeed, whether they exist upon a free surface, or upon the wall of a cavity which is of their creation

As already stated, the tubercle grows peripherally, *i e*, the central one having softened, its contents rapidly invade adjacent parts to add like growths to the central mass And so minute are the single growths, that a compound tubercle of the size of a poppy seed is made up of at least *thirty six* sub miliary nodules (Rindfleisch) Another method of peripheral enlargement consists in the coalescence of adjoining tubercular masses—this concentric and peripheral growth proceeds until the base of a terminal bronchus is surrounded by a tubercular mass which is known as Carswell's grapes Hitherto, as is often the case, tubercles have been, and most unjustly so, described and figured as the cause of the disease, and yet they are only so many monuments to friendship, unwise friends, we are willing to admit, who have in their component parts, the cells, paid their friendship with their death

Tubercles are not disease, but nature's method of staying disease and death, for as long as they themselves remain untouched by decay they are harmless to the economy Yet, like too assiduous friends, they may overdo their good offices (though we suspect it is the fault of the anatomical relations of the parts and the importance of their functions to the economy)—they grow until not only the bronchial twig but the pulmonary vessels, the artery in particular, are strangulated either by the masses which surround them, or by the invasion of the tubercles into them, and in both instances, though not a typical embolus results, the consequences are exactly the same, the tissue dies invariably, and when removed it leaves a cavity This is the case whether the process proceeds from the surface of a mucous membrane, as that of the intestines, or from the situation just described We said a *cavity* purposely, and not an *ulcer*, for this, after the necrosed tissue is removed, presents a granulating surface bathed in pus, indicative of an effort at redemption Whilst the wall of the cavity presents nothing but necrosed and dying tissue, made uneven by larger and smaller masses of tubercles in all stages of development and decay This is the picture of chronic tuberculosis pulmonum

Acute miliary tuberculosis of the lung presents in its causation an entirely different aspect, though the final issue is identical with the one just described *It consists most generally in a multiple embolism of the capillaries of the pulmonary artery, induced not by bacilli or their germs, but by debris from softened foci (glands more often) with bacilli in and on them, which have found their way into the circulation* In this causation two other sources must be included direct injection into the circulation of the virus in sufficient quantity, and reversion of the lymph stream Inoculation of the virus belongs in the first category, as miliary tuberculosis is noticed only after the formation of tubercles *in loco* Direct injection self evidently reverts to the first category also, the place of the introduction of the poison not being considered Reversion of the lymph stream as a cause of miliary tuberculosis of the lung has only of late obtained a safe foundation by the observations of v Recklinghausen In cancer of the bronchial glands, it is not seldom that metastases are found in the subpleural tissue The same transmission must be admitted for broken down tuberculous material from the same glands The infective embolus, for such it is, provides all the conditions we have found in the bronchi, and have claimed as necessary for the multiplication of the bacilli and their succeeding destructive work All subsequent infiltration of the tissues is identical with that of the bronchial disease, with this difference only, that in the latter the infiltration is primarily located in the *peribronchial* lymphatics, whilst in the former it is found in the *perivascular* lymphatics, and that in this the processes are generalized, and in the other they are lo calized. And finally, that infection of both lungs ensues from all the sources mentioned but one, reversion of the lymph stream, in which the general tubercular formation is unilateral in the earlier stages of the disease.

To strengthen the scientific basis of the treatment of tuberculosis we must mention the freedom from *this disease enjoyed by persons* with lesions of the heart, of which mitral stenosis is the one most rarely complicated with pulmonary tuberculosis. Ruehle, in Ziemssen's "Cyclopædia," page 507, says: "The correctness of the general statement must probably be admitted." And after giving Traube's view, that the more copious effusion from the pulmonary vessels, whereby the dessication and caseation of morbid products are promoted, is perhaps the reason for this exemption from the disease, he dismisses it "because a discussion of *hypotheses* (italics mine) is out of place here." I certainly agree with him as to the impropriety of the discussion of hypotheses in a lengthy paper like his or ours. Yet the great clinician's (Traube's) view can no longer be classed with hypotheses. It is a fact that in all the lesions of the heart which seem to lessen the occurrence of tuberculosis pulmonum the right ventricle is hypertrophied, and this hypertrophy is not caused by an interference with the blood current between it and the lung, but between the lung and the general circulation, within the province of the left heart. The changes produced, in consequence of these lesions of the heart, in the lung, are strictly in keeping with the conditions required to prevent the occurrence or the development, to any extent, of the lesions of tuberculosis in the lung. It is a clinical fact that the hypertrophied right ventricle will induce congestions in the lung, particularly if the blood stream is impeded on the left side of the heart. This chronic pulmonary congestion is followed by two sequelæ—an interstitial connective tissue hyperplasia (cirrhosis of the lung) and an increase of the velocity of the lymph stream, both conditions which our exposition will warrant us in accepting as diametrically opposed to the development of tuberculous lesions. Indeed, the latter function, the ready flow of lymph, is so very important, that its maintenance and its increase become the momentous questions in a rational treatment of the disease. That this is normally brought about by congestions, by the active contractions of the muscles of a part, by deep and often repeated in and expirations, and by the normal relation of the histological elements of the tissue, needs no demonstration.

Stress is here put upon *the artificial increase of this* function by Cohnheim's experiment. He observed the lymph stream from the thoracic duct increased twenty five times, when he injected into the circulation forty per cent. of the body weight of a $\frac{6}{10}$ of one per cent. solution of chloride of sodium in distilled water. Much, indeed, has been said of the prophylactic treatment of tuberculosis, and much more is yet unspoken, and far more unheeded. Prevention in this disease simply means a shutting out from the economy of Koch's bacillus. To enumerate the means by which this ought and can be done, would necessitate the incorporation in this paper of everything that hygiene has suggested to keep air pure as the breath of life. The worst of all breeding places for tuberculosis is the crowded work shop, illy ventilated and overheated, and in which work is performed which produce dust full of irritating particles. The least offensive place is a mountain home, in an equable, dry and rather cool climate, where you are your own neighbor, and the only one. To enumerate the methods of infection would prove an equally herculean undertaking. From the mother's blood (Johne) and her mouth and lips (Herterich), from inoculations through trivial injuries, as a cut in the finger (E. A. Tscherning), or the dentist's forceps (the author), from inhalation of the poison in home, school, work shop, crowded hall and prison cell, from food and clothing, tuberculosis may take origin. It is certainly very careless, nay, criminal, if the author's explanation why measles and *pertussis* are so likely to be followed by tuberculosis (and this is a fact) is correct, to permit a child sick with these disorders to remain in the company of a person suffering from tuberculosis. It should never be allowed if it can be avoided.

The cure of diseases and conditions which favor the development of tuberculosis forms, of course, a very important part of the prophylaxis of the disease. Besides this, any and all means which favor the restoration or the maintenance of the highest vitality to the elemental parts of the lungs, as well as of the whole body, are of the greatest importance not only in the prevention, but also the cure of tuberculosis. It is self evident, from what has been said, that the specific cure of tuberculosis demands, in the first place, the destruction of the bacillus. Much has been suggested and done in this direction to warrant the hope of final success. This presumably lies in the direction of inhalation of parasiticides, and their injection by the nearest and most direct channels practicable. And if these inhalations and injections contain the means (alkaline or neutral solutions) for the solution of the tubercles, then the cure of the disease will become a scientific certainty. It is not the object of the writer to burden medical literature with an exhaustive essay upon tuberculosis, such have been furnished often and by abler writers. He will therefore not be charged with omissions—that mention has been made in a general way only, of the treatment which to day receives universal sanction.

The heart should be induced to do its best by stimulants and tonics, to establish the conditions described at length, which will curtail the disease, namely: *remove impediments to the free circulation of fluids* in the lung and favor cicatricial growths around tubercles and their cavities.

The sewers of the body, particularly the kidneys, should not be neglected, rather stimulated to remove all effete matter promptly and thoroughly from the body. Enlarged glands, wherever situated, particularly on the neck, and in reach of the hypodermic syringe, should be made harmless by injections of iodine and carbolic acid (as has been twice successfully done by the writer). Cod liver oil should never be omitted, because of its undoubted influence in removing or preventing the formation of scrofulous tissue

In what has been said no attempt has been made to explain the manner or cause of the formation of "scrofulous tissue" That it is acquired *intra vitam* no reasonable doubt can be entertained, and for its inheritance an array of facts speak, which are invincible The *why* in both instances is yet *sub judice* The writer has little doubt that in its proper time it will be shown that the digestion, assimilation and reappropriation (burning) of fat in the economy, and particularly its relation to the proper maintenance and rejuvenation of the tissue elements furnish the field upon which the pathologist will have to seek for a solution of this anomaly of the connective tissue and its lymph spaces Even the crude conception of oil as a *lubricant* for man's economy (which is so often likened to an engine), opens a vista of thought far too vast for the limits of this paper The formation of cells from dividing protoplasm is unthinkable without the intervention of fat, a conglomerate of cells is easily produced without this separating medium Indeed, the distinguishing feature between caseation and softening, and suppuration, seems to be the absence of fat in the former For this, and the poverty of blood supply (not to forget impeded absorption by way of the lymphatics), produces the non-separation of the cell conglomerate, and, when the circulation is altogether strangulated, death of these elements and destruction by caseation, and removal by the intervention of softening Whilst in suppuration, hyperæmia in the presence of fat produces a rapid multiplication of cells, *i e*, the formation of pus corpuscles These are some of the thoughts which urged the necessity of the use of oil in this disease, cod liver oil particularly, since it is one of the most easily digested of fats, and perhaps because its natural combination with iodine makes it more capable of entering into intimate relation with the watery compounds of albumen in the tissues, thusly facilitating the interchange of fluids and the multiplication of cells, and the rejuvenation of the tissues Finally, the use of iodide of potassium is again urged upon the profession as a remedy which may yet prove itself the chief anchor in this disease

If the author's knowledge of the disease will entitle him to an innovation, a suggestion for the treatment of it, he will urge upon his fellows, particularly those connected with large hospitals, the trial of subcutaneous injections, in the neck particularly, of iodide of potassium and a small dose of iodide of mercury—say five grains of the former to gr $\frac{1}{50}$ of the latter, highly diluted, and as often repeated as good judgment will warrant, as the most rational specific medication which, in the writer's opinion, it is possible to deduce from the nature of the disease And, if to this be added a careful observation of all the suggestions which experience has sanctioned, together with a never resting battle, by word and deed, against the spreading of the tubercle bacilli, we will succeed as never before in preventing and curing the disease

Ashland, Nebraska, December, 1885

A GRAVE CASE OF NERVOUS DYSPEPSIA CURED BY MASSAGE AND REST IN BED

BY M STAMM, M D,

OF FREMONT, OHIO

It is not my intention to enter fully into the details of nervous dyspepsia, especially as its clinical picture is rather vague, and presents a complex of symptoms of the greatest variety But the literature of recent years has furnished sufficient data to demonstrate that there are such affections of the stomach, which differ materially from the diseases of the chylopoietic system, otherwise described and classified, and which for the present may aptly be brought under the head of "nervous dyspepsia" Doubtless almost every busy practitioner has met with cases which presented such vague symptoms, and he vainly looked about for a description or a name which might approximately cover the picture presented Our text-books of recent date make but short mention of it The name "nervous dyspepsia" itself betrays the fact that we have no clear understanding of the pathological condition further than that the nervous system furnishes the prominent basis of these manifestations Authorities are not agreed yet whether the changes are of local or central origin in the nervous system

The cases thus far reported tend to show that some are due to functional disturbance of the pneumogastric nerves, and others to the ganglionic system Another class of cases, again, may be referred to some abnormal condition of the central nervous system, especially cases due to mental influences, as care anxiety, etc From this we may see that it is no easy matter to form a diagnosis at the beginning, and that sometimes only the futility of the treatment instituted for the more common affections of the stomach and the obstinacy of the case will help to lead us on the right road Worse than that, there are cases in which post-mortem examination alone will open our eyes, as a late report of a meeting of the London Medical Society graphically shows Before that great body of highly scientific men Dr Stephen Mackenzie, in a very instructive paper, mentioned two cases of apparent gastric disease, in which post-mortem examination failed to reveal any certain evidence of disease of the stomach, though the gastric symptoms were even definite enough to excite more than a suspicion of the presence of gastric ulcer Indeed, one of the cases had been diagnosticated by more than one physician as a typical clinical case of the affection, whereas *post mortem* it was admitted to be a case of *apepsia nervosa* Dr Stretch Dowse, in the discussion, even ventured the opinion that perforating ulcers of the stomach were invariably of nervous dystrophic origin Besides the difficulty of diagnosis, we may see that such cases even sometimes may terminate fatally, at least, that the treatment hitherto applied and recommended is not always followed by the desired effect Such cases are generally looked upon as the *crux medicorum*, and not unfrequently go from physician to physician, and finally into the hands of quacks

It may therefore not be out of place here to refer to a treatment which, in the case mentioned below, had a surprisingly rapid effect We all know what striking results the Weir Mitchell method of treatment will accomplish in some grave cases of hysteria and neurasthenia, especially when the state of nutrition has been very much lowered And just the experience in a few such cases under my hands has led me to the remark, made about a year ago before the Sandusky County Medical Society, when the subject of nervous dyspepsia was brought up for discussion, that a similar treatment might result in much benefit in the latter affection The rapid improvement and recovery in the following case, as well as the absence of any symptoms of hysteria and neurasthenia, may well justify the diagnosis of nervous dyspepsia,

Mrs B, æt about 27 years, married five years, had two children, neither of which she nursed herself Her health up to one year and a half ago was excellent About that time she suffered from intercostal neuralgia, which, however, was soon relieved by treating a cervical catarrh of the uterus At times subsequently she would complain of a slight pain and pressure in the epigastrium, her appetite did not suffer any, and restriction of diet would soon relieve her of those feelings About the first of August, 1885, the patient experienced shortly after meals a severe pain in the left epigastric region, which was frequently followed by vomiting She would not admit any error in her diet, and it was impossible for me to find any other cause for her symptoms Repeated examinations of the urine and sexual organs revealed nothing abnormal She could bear very little food, and the various medicinal agents which her gastric symptoms and pain called for had merely a palliative effect, pain and vomiting would frequently recur A case reported by Glax (Volkmann's *Klin Vortrage*, 223), which exhausted all his therapeutical skill and change of climate without any avail, and finally, after he became dropsical, resorted in his despair to exclusive milk diet with the result of complete recovery, induced me to order such a diet in my case It had the effect of lessening pain and vomiting, in fact, subdued it entirely, until she again tried more substantial food This milk diet she kept up for about six weeks, which markedly improved her symptoms, although the emaciation made steady progress Beef peptonoids, which also were tried, produced nausea and vomiting, I think principally owing to their looks and taste Although Mrs B, who in her health was always of a very patient nature, exhibited, *pari passu* with her gradual emaciation, some irritable disposition and signs of weakness, she never showed any real symptoms of hysteria or neurasthenia About the beginning of October she visited her parents living in a larger city, and was there under medical care During her visit her condition was only changed to the extent that her stomach could bear solid food and turned against milk, but her emaciation continued Indeed, in December, when I saw her again, I found her reduced to a skeleton, and could hardly suppress the idea that a deeper organic change was at the bottom of her complaint I accidentally dropped the remark in presence of patient that general massage and rest in bed, with proper feeding, might possibly give her some benefit, when she enthusiastically took up the idea, having heard of some splendid results by Weir Mitchell's plan of treatment in cases of hysteria and neurasthenia I must confess her appearance at that time, the pain and vomiting having returned, did not inspire me with great hopes as to a cure I therefore thought it prudent to propose only a trial of ten days

As her nurse was not just ready to begin massage, I again put her on milk diet for about a week During that time she only vomited once after having taken bread with her milk, her pain also had decreased considerably The beginning of the treatment was fixed for December 24, and as she was free from any signs of hysteria and imbued with such implicit confidence in the result, the treatment was carried out at her own home, which in hysterical cases should absolutely never be undertaken,

In the first four days Mrs B complained of slight pains and pressure over her stomach, turning on her right side would especially increase her pain, but from that time on she experienced a feeling of unwonted well being and enjoyed excellent sleep Her bowels, which always before showed a tendency to constipation, began to move regularly, and after the sixth day she indulged in a bill of fare of rather liberal selection As she reached the tenth day, the end of the proposed period of trial, she concluded to continue the treatment up to the end of six weeks, finding that the stomach made not the slightest remonstrance against those enormous quantities of food which Mitchell and Playfair urge upon their patients In this manner she uninterruptedly followed the road to recovery, and although she has not accumulated such a mass of adipose tissue as some would perhaps lay up, she now presents a picture of perfect health

Fremont, Ohio, February 22, 1886

MEDICAL PROGRESS

Thoracic Aneurism treated by the Introduction of Steel Wire into the Sac —At the meeting of the Royal Medical and Chirurgical Society, on February 23, Dr W Cayley read the report of this case The patient was a man, aged 48, who was admitted into the Middlesex Hospital on June 5, 1885 He had been suffering from symptoms of a thoracic aneurism, since November, 1884, but it was not till five days before his admission that a pulsating tumor made its appearance at the root of the neck, rising about three inches into the neck behind the right sterno clavicular articulation The patient was at first treated according to Tufnell's method, and given large doses of iodide of potassium The tumor continued to increase in size, and it was evident that it must either soon burst externally, or extravasate among the tissues of the neck On June 24, Mr Hulke introduced into the sac, through a fine canula, forty feet of steel wire This caused no constitutional disturbance or local pain, and this portion of the aneurism became completely consolidated Towards the middle of August, signs of the extension of the intrathoracic portion of the aneurism—increasing dyspnœa, and severe paroxysmal cough—became more marked, and there was an increase of pulsation behind the sternum, and towards the left sterno clavicular articulation As it was evident that the aneurism must soon prove fatal from pressure on the trachea, it was determined to endeavor to consolidate the part of the sac producing this pressure Accordingly, on September 10, Mr Gould, in the absence of Mr Hulke, introduced a canula just above the left sterno clavicular articulation, directing the instrument obliquely towards the middle line, and introduced thirty-four feet nine inches of wire No constitutional disturbance followed, but no relief was given to the symptoms, and the patient died in a paroxysm of dyspnœa on September 19 On *post mortem* examination, a large aneurism was found springing from the ascending part of the arch, and communicating with the vessel by a very large orifice, the whole of the upper portion was completely filled by a clot, embedded in which was the wire The wall of the aneurismal sac, where it projected into the neck, consisted only of a little condensed connective tissue The lower portion of the sac, near its origin from the aorta, caused compression and flattening of the trachea, just above its bifurcation The first operation produced the desired result in preventing the imminent rupture of the aneurism The size and connections of the sac rendered the second operation ineffectual

THE PRESIDENT congratulated Dr Cayley and Mr Hulke on their prolongation of the patient's life He had seen all cases of large thoracic aneurism under his care die, except one, and that was in a man of 70, who died of old age thirteen years after clear signs of a large thoracic aneurism had shown themselves The dangers from this treatment by the introduction of wire, he was inclined to think threefold, first from the local irritation induced, as had happened in Mr Moore's case, secondly, from embolism, which might take place in the brain or kidneys, and, thirdly, from the ulceration in the sac, which might be caused by the end of the wire MR R BARWELL could hardly think that the value of this method was as yet thoroughly determined He believed that this was the ninth published case The first was Mr Moore's well known case, the second, a subclavian aneurism, into which Dr Levis had introduced horsehair, the third, a case of popliteal aneurism, into which Mr Bryant had also passed horsehair, the fourth, a case of innominate aneurism, under Dr Rubio, of Madrid, treated by wire, which showed no change of symptoms during the first four days, but after that was lost sight of, and must be presumed to have died, the fifth and sixth cases, under Bacelli, the seventh, a brachial aneurism, under Van der Meulen, into which catgut was introduced, a proceeding which deserved considerable attention, as it avoided irritation, the eighth, a remarkable case of abdominal aneurism, under Professor Loreta, which was treated by abdominal section and separation of the aneurism from its surroundings, and the introduction of six and one-half feet of wire The case did well till the ninety-second day, when the man died suddenly of rupture of the aneurism, just at its point of junction with its entrant artery The aneurism, after death, was found to have in part consolidated, a result he was inclined to attribute to its manipulation, rather than to the small quantity of wire introduced The ninth case was this now before the meeting, of Dr Cayley's and Mr Hulke's in which the man had survived the operation eighty six days The record could not be considered encouraging, and for his own part, he had not been tempted to adopt the operation

DR J LISTON PAUL, whilst surgeon to the General Hospital, at Madras, had had a case under his care in 1874, which he had treated in a somewhat similar manner A native had been brought to him with a very large innominate aneurism, bulging forward on the left side of the sternum, into this he had passed fifteen feet of white cleansed horsehair Slight pain and pricking over the tumor had followed In three days the tumor had grown larger, and gave greater distress, on the fourth day the patient died in a convulsion No search for emboli was made

MR BRYANT was very glad that this method of treatment was again brought under discussion, as he was disposed to think it applicable to more cases than was generally imagined Of course it could only be thought of in those in which pressure, or manipulation, or ligature, was quite impossible All such forms had but a faint chance, but in them the introduction of a foreign body should be attempted, if they were within reasonable reach He preferred horsehair, or fishing gut, or catgut to wire, for the danger of irritation from wire was considerable In his own case, to which Mr Barwell had referred, the man was dying of ulcerative endocarditis, his treatment of the popliteal aneurism with horsehair, had consolidated it, and had so far lengthened life that it had prevented death from its rupture, which was imminent In applying the treatment to aortic aneurism the greatest difficulty would be in diagnosis, but, granted that that could be ascertained, he should consider the treatment most justifiable, and also in the case of abdominal aneurism

MR HOLMES said that he felt strong encouragement from Mr Bryant's case, for the specimen showed clearly the progress that had been made towards cure, and Professor Loreta's case tended to the same conclusion He could not agree with Mr Barwell, that in that case the consolidation had been brought about by manipulation, a careful examination of the specimen showed the wire as the focus of the clot The method had been originally suggested in a meeting of the Society, by Dr Murray, of Newcastle, and he was under the impression that he had made some trials of it To him they also owed the suggestion of the method of rapid compression under chloroform There were many cases in which their choice was limited to two alternatives, treatment by electrolysis or by introduction of a foreign body In his own experience, electrolysis had given purely negative results, others had done better with it, notably Ciniselli In Mr Moore's case, thirty-six yards of rather rigid wire had been used, and he had little doubt it was too much, and had set up inflammation, but he had no hesitation in recommending, with Mr Bryant, either horsehair or catgut, and of the two he rather preferred horsehair, as it does not melt away (which is the chief objection to catgut)

Mr Hulke disclaimed any credit for the paper, which was entirely due to Dr Cayley, but was glad to find that the subject aroused attention The President had suggested three dangers from the operation, the first was of local irritation In Mr Moore's case, the wire was of soft iron, which might easily have passed into the tube of the aorta, not tempered steel, as in Dr Cayley's case For his own part, he had still to learn any method of distinguishing whether the opening from the aneurism into the aorta was large or small The steel wire which he had used had been carefully coiled beforehand, on a mandril half-an inch in diameter, and he presumed that it would coil up again within the aneurismal sac He passed the wire through a Southey's canula, in which were lateral holes, when sufficient had been passed, the end was cut with some effort, and slightly bent, this bent end caught in a hole in the canula, and when the canula was withdrawn, the end of the wire was left out, and pinned the coil of the wire in the aneurism to the chest wall That seemed at first unfortunate, as leading to some bleeding, but very possibly its counter-balancing advantages were greater, for it made it impossible that the coil of wire should fall from the aneurism into the main stream of the aorta If horsehair or catgut were used, he could not feel sure how or where they would travel in the aneurism, nor could they be made certainly aseptic, catgut might be carefully treated, and yet give deadly results if it had been taken from animals dying of *milz-brand* Of the possible methods of treatment, he considered the injection of ergotin in the neighborhood of the aneurism, as suggested by Von Langenbeck, as no longer worth discussion, the treatment of electrolysis in his own hands had proved positively disastrous, if the needles used were fine, they grew hot, and caused sloughing, if they were insulated, great force was needed to push them through the sac of the aneurism The only remaining treatment was that by wire, and the arguments for that were in some cases strong

Dr Cayley considered that the risk of embolism, which the President had suggested, was not serious, it had occurred in Mr Moore's case, not from the treatment of the aneurism, but from the ulcerative endocarditis He admitted that it was impossible to be certain in any diagnosis of a large opening into the artery from a small one, but, roughly speaking, a louder bruit indicated a narrower opening He was able to assure Dr O'Connor that there were no bubbles either in his case or in Mr Moore's —*British Medical Journal*, February, 27, 1886

Action of Mercury on the Blood in Secondary Syphilis and in Anæmia —The influence of the salts of mercury on the circulation has been recently the subject of a most thorough and strictly scientific clinical study by **Dr L Gaillard** (*Archives Generale de Medecine*, November, 1885) The subjects on whom the first series of observations was instituted comprised

1 Syphilitic patients without or with a slight anæmia

2 Syphilitic individual with an advanced state of anæmia

3 Syphilitic individual also with an advanced state of anæmia, but in a condition of mercurialization

Gaillard's conclusions are as follows

In the first group a diminution of the number of blood globules and of the hæmoglobin could be observed in the course and at the end of the mercurial treatment

In the second group a favorable result could rapidly be noted, both the number of blood globules and the hæmoglobin increasing considerably and in a short time

The subject of the third observation was not improved The anæmia had no tendency to disappear, even after the effects of mercurialization had passed away There was an evident intolerance of the drug, which must be borne in mind both regarding prognosis and the estimation of the therapeutic result

Comparing these results, we see that the second category, representing syphilis and anæmia, profits most from the tonic and reparative action of mercury It is hence in these patients that we can look upon mercury as a restoring and augmenting agent of both blood globules and hæmoglobin This refers only to the red blood corpuscles, the white ones were nevertheless counted by Gaillard in each instance Their number appears to diminish under the influence of mercury, as has also been as early as 1874 by Wilbouchewitz [Still it appears hazardous to make any definite statement in this respect We all know the instability and variance locally and numerically of the white blood corpuscles Remembering their abundance in persons affected with even slight suppurations, we would not be surprised to see them decreasing in a woman suffering with vaginitis after the cure of the local trouble]

The second series of observations refers to the action of mercury on the blood in anæmia The patient took ordinary doses of either the protoiodide of mercury or of the sublimate The obtained results are comprised in the following theses

1 The number of red blood globules can decrease in anæmic persons under a mercurial treatment in the beginning without reattaining the original numerical status More frequently, however, they increase in number progressively up to the fourteenth day, when a slight reduction takes place again

2 The hæmoglobin increases daily and progressively up to the twenty fourth day, then it is reduced toward its original figure, but surpassing it still, if the treatment lasts for several weeks

3 The hæmoglobin increases more considerably in proportion than the red blood corpuscles It increases even when the latter diminish in number, so that mercury can be placed alongside of those metals which elaborate hæmoglobin

4 The bodily weight increases nearly constantly under a mercurial treatment Still, we are unable to establish an exact relation between this phenomenon and the condition of the blood —*Therapeutic Gazette*, January 15, 1886

THE
Journal of the American Medical Association
PUBLISHED WEEKLY

THE EDITOR OF THIS JOURNAL would be glad to receive any items of general interest in regard to local events or matters that it is desirable to call to the attention of the profession Letters written for publication or containing items of information should be accompanied by the writer's full name and address, although not necessarily to be published All communications in regard to editorial work should be addressed to the Editor

SUBSCRIPTION PRICE INCLUDING POSTAGE
PER ANNUM IN ADVANCE $5 00
SINGLE COPIES 10 CENTS

Subscriptions may begin at any time The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned When neither is accessible remittances may be made at the risk of the publishers by forwarding in REGISTERED letters

THE ETIOLOGY AND PREVENTION OF RABIES

At the meeting of the New York County Medical Association on March 8, DR HERMAN M BIGGS, Instructor in the Carnegie Laboratory, who recently visited Paris to study Pasteur's methods with regard to rabies, read a paper on "The Etiology of Rabies and the Method of M Pasteur for Its Prevention" It is not necessary to give in detail his argument for a specific origin of the disease Suffice it to say that he expressed the opinion that the occasional spontaneous development of rabies in certain of the carnivora, as advocated by many distinguished veterinarians, must be entirely rejected in view of the facts recently demonstrated with relation to the germ diseases, and that we must accept absolutely the conclusion that this disease is maintained and spread solely by its contagious principle, there being no other causes in operation Hence it is a matter of great importance that the fallacious ideas prevalent among the laity, and to no small extent among the profession, in regard to the influence of climate, season, hunger, thirst, food, pain, anger, ungratified sexual desire, etc, as predisposing or exciting causes, should be corrected There are no more reasonable grounds for believing that any or all of these influences combined can bring about the development of a single case of rabies, than that unfavorable sanitary conditions can produce small-pox when the specific *contagium vivum* of that disease is not present A wound or injury produced by the teeth of a non rabid dog, one whose saliva does not contain the living organism (whatever may be its nature), which is the essential cause of the affection, can no more bring about the specific disease which we call rabies than can the wound made by a sterilized knife

In regard to the nature of this *contagium vivum*, said Dr Biggs, we have no absolute knowledge, except that it must be a living matter capable of reproduction and multiplication when transferred to the living organism, and there producing a specific disease manifested by varying symptoms in the different species of animals affected, of whose presence or virulence we can only know by the results produced when introduced into the blood of previously healthy animals That it is exceedingly minute is shown by the difficulty experienced in its demonstration, and that it is a micro organism belonging to the schizomycetes is rendered probable by the similarity to other known pathogenic micro organisms, as regards the mode of its transmission and development Some of the conclusions arrived at by Pasteur in his earlier work have not been confirmed either by his own later investigations or those of other observers, and are in some respects opposed to the results recently reported Unfortunately, too, in his last communications he has not discussed the question so much in detail as could be desired, nor has he given definitely the number or character of the experiments upon which his conclusions and the general principles drawn from them are based The efficacy of Pasteur's present method was proven by inoculating fifty dogs, with success in every case in rendering the animals refractory to rabies After having arrived at these results Pasteur felt justified, after consultation with MM Vulpian and Grancher, in inoculating the boy Joseph Meister, who unexpectedly presented himself for treatment July 6, 1885 In order to determine the virulence of the virus used in this case two rabbits were each day inoculated in the usual manner with the same virus as that used for the boy These inoculations showed that the cords used on July 6, 7, 8, 9 and 10 were not virulent, since they did not produce rabies in the rabbits inoculated on these days The cords used on July 11, 12, 14, 15 and 16, however, were all virulent, and of a constantly increasing virulence Rabies appeared after seven days of inoculation in the rabbits inoculated with the cords of July 15 and 16, after eight days in those of July 12 and 14, and after fifteen days in those of July 11 Notwithstanding that in the last inoculations virus was used which was far more virulent than that of rabid dogs which have contracted the disease in the ordinary way, these inoculations were followed by no symptoms whatever, and though more than six months have elapsed since the treatment, the boy still remains in good health

The interpretation which Pasteur gave of the prophylaxis against rabies afforded by his method, by which an alteration in the virulence of rabic cords is produced by the process of dessication, was, that the continuous contact of the dry air brings about a gradual diminution in the intensity of the virulence of the cords, until it finally becomes extinct, that the prophylactic method in its application depends for its efficiency upon the employment at first of a virus without appreciable activity, followed by a weak virus, and then by a more and more virulent form, that the diminution of the virulence of the cords is due to an impoverishment in *quantity* of the virus contained in the cords, and not in the impoverishment in *virulence* Consequently, in the inoculations, the virus used is always identical as regards its virulence, and is variable only in respect to the quantity employed, so that the condition refractory to rabies follows from the employment of very small, but constantly increasing, quantities of virulence This interpretation of the method of action of the virus, said Dr Biggs, is the more interesting, inasmuch as a new and quite different principle is involved from that obtaining in the vaccine for small-pox or the vaccines devised by Pasteur for the prevention of anthrax, chicken cholera and typhus in pigs In small pox we have a virus modified in character and virulence by its passage through another species of animal, in anthrax, chicken cholera and typhus in pigs we have a virus modified in respect to its virulence by the conditions of temperature to which it has been subjected during its developmental growth, and, finally, in rabies we have a prophylactic method dependent upon the employment of a virus always constant as regards its virulence, but used in very small and constantly increasing quantities

As to the duration of the refractory condition (to rabies) after inoculation, Pasteur believes this to be not less than one year, probably considerably longer, but as yet no data are available on this point With regard to the conclusions as to the accuracy of Pasteur's observations and methods, Dr Biggs thinks that the strongest evidence of the efficacy of the methods for the prevention of rabies rests upon the results of the experiments upon dogs If Pasteur had been able not only to render fifty dogs refractory without a single failure, but had also prevented the development of rabies in a larger number after they had been bitten—both of which he asserts he has positively accomplished—then the question as to the prevention in human beings is only as to the method of application Dogs are far more susceptible and liable to the disease than human beings, and the character of the disease being evidently the same in both, if dogs can be made refractory it is not assuming too much to conclude that the same is true of human beings In concluding his paper Dr Biggs frankly acknowledged that the evidence as to the efficacy of Pasteur's methods is not altogether satisfactory But in the light of his former brilliant and valuable scientific work is it probable that he could have spent six years of study to rabies without getting some substantial result? Or does it seem probable that he has been dealing all these years with some form of septicæmia, as has been suggested, laboring under the delusion in the meanwhile that it was rabies? This I cannot believe, and if it is not true, then Pasteur's conclusions must be in the main correct, for certainly no one will question his honesty "

As to the spinal marrow being employed as the agent for transmitting the virus, Dr Janeway said, in the discussion of the paper, that it seemed to him entirely appropriate the manifestations of the disease showed that the germ of the disease was in the spinal cord and medulla oblongata as well as in the saliva, or, if this was not the case, that it circulates as a specific poison in the blood and acts as an irritant upon the nervous centres He thought that there was no reason to doubt that dogs had been made refractory to rabies by Pasteur's method, while in human subjects it had at least proved harmless in more than three hundred cases

It is an indisputable fact that Pasteur has for years been experimenting with a disease which almost without exception runs the same course and produces the same symptoms, the period of incubation in rabbits being always about fifteen days We must entirely agree with Dr Biggs that if, as some assert, this affection be a form of septicæmia, if must be an entirely new form, since no variety of it is known which has a period of incubation in rabbits of fifteen days After cultivation the inoculation in rabbits is seven days, and in dogs eight or nine days In regard to the suggestion of Dr Flint, Jr, that control experiments should have been made, such as the injection of bouillon subcutaneously, to which no spinal marrow was added, Dr Biggs said that inoculations had been made subcutaneously and into the veins, instead of under the dura mater after trephining, the only difference that had been noted in the result was, that the period of inoculation was longer under these circumstances The reason why Pasteur adopted the method which he now employs was because he found, after many experiments, that with it the period of inoculation is shorter, and the process more certain, than when any other method is used Pasteur has inoculated dogs which were placed in cages with and had been bitten by rabid dogs, and *in not a single instance* did rabies result These experiments have been frequently tried under the supervision of the official commission appointed to investigate the matter, and this evidence is of the greatest importance in establishing Pasteur's claims as to the efficacy of prophylactic inoculation of rabies

"ACADEMIC STUDIES IN RELATION TO MEDICINE"

In the department of Domestic Correspondence in this issue of THE JOURNAL will be found a letter on this subject by DR R LOWRY SIBBET, of Carlisle, Pa It will be remembered that Dr Sibbet read a paper at the last meeting of the American Academy of Medicine entitled "The Study of Medicine as a Means of Education," which was editorially noticed in THE JOURNAL of January 9 The present letter from Dr Sibbet must be taken, it seems, as a reply to our editorial notice of his paper

It is an evidently untenable proposition to say that *any* educated man, with large experience in any direction, is in a position to tell a boy what studies he should pursue as preliminary to the study of medicine The President of Yale College is an educated man, and one of large experience, but surely he is no more fitted to speak dictatorially on this subject than many a well read, clear headed physician who sees reflected in himself the evils and mistakes of the ordinary classical course "An educated man" is a relative term, with nothing fixed or definite in it We cannot reason correctly unless we know the data from and upon which we reason It is incorrect to say that one who has not pursued a study (such as mathematics) for a series of years is not in a position to judge of its relative value as a means of education In view of the statements made in his paper before the American Academy of Medicine, Dr Sibbet's use of the words "mathematics" and "languages" is entirely too broad for this discussion We showed in our editorial that there is a great difference between ancient and modern mathematics, and it is useless to repeat what was then said Hence we cannot argue the matter when our correspondent fails altogether to define his position, which is entirely different, as we shall show, from that taken in his first paper In that paper he mentions only two languages, Latin and Greek In point of training value one language has no advantage over another It is a very simple matter to define and specify the mental processes involved in studying different subjects, and this is all that is required in determining the training value of any subject or study To deny this is to confound the machinery of thought with thought itself, to mislead ourselves and make no progress, and to obscure the whole subject in a verbose fog of unwarranted assumptions

In the propositions stated under (1) Dr Sibbet argues entirely beyond the question at issue No one has proposed that medical men, or those of any other profession, should regulate education or the curricula of colleges He asserts in his first article that a man *must* be thoroughly grounded in Latin, Greek and mathematics in order to be fitted for the study of medicine We denied that those studies are absolutely essential for a preliminary education for medicine, or for training the mind, intellect or faculties (or whatever we choose to say), and we *gave our reasons* for the denial Dr Sibbet has not shown that our reasons are incorrect, nor has he asserted that we reasoned from insufficient data He adduced no proofs of his assertion, but evidently, as is so often the case, the assertion was made on the authority of that long list of classicists who have said the same thing over and over over again without bringing forward one iota of proof, or giving any reasons for it that would stand analysis In his first article he did not refer to the value of scientific education (academic) or to science at all, except so much "as is usually taught in respectable classical colleges"—which means, usually, none at all Why then does he now speak of "elective courses," which, as would be inferred from his article, he does not recognize as proper courses of study? It is seen that he has now changed his base of argument almost entirely, as he really acknowledges that a youth may, after all, be educated without being forced through the classical course It is a mistake to say that the medical profession in the United States has ignored every standard, academic and medical, and in proof we may point to the Seventh Annual Report of the Illinois State Board of Health

His answer to the question, Where should a student who desires a good education prepare for the study of medicine? is in a classical, scientific or literary institution How does this accord with what he says in his first article that the student (before studying medicine) has "studied mathematics, languages, rhetoric, mental and moral philosophy, and as much chemistry, geology and astronomy as is usually taught in respectable *classical* schools To all such we would say that they have laid a solid foundation upon which to add professional studies Their education has been in all directions, not merely one class of mental faculties, but all have been exercised and disciplined" If an education *in all directions* can be obtained in a classical school, it must be evident that such cannot be the case in any other school, since the methods in the different schools are essentially different He has thus placed himself in the anomalous position of recommending schools which, as he has shown, he considers objectionable But the truth is, there is no system of education which will educate in all directions He evades the question, which he asks, What shall a student, who desires a good education, study until he is capable of deciding what he should do in life? His statement, under this question, that educated men in all countries and for many centuries have presented and advocated a combined classical, scientific, and literary course of study as the very best that can be devised for young men who desire to enter the learned professions, is singularly inaccurate Three centuries are not *many*, and that is a liberal allowance for the age of our classical system In the statutes of the University of Paris of 1600 the studies in arts are defined as Latin, Greek, Aristotle's Philosophy, and Euclid Scientific and literary studies had no part or lot in the education of that period Inasmuch as our science of to-day can scarcely be said to be one century old, it is manifestly absurd to say that it has been advocated for many centuries It is not less absurd to hold that the preliminary education for the medicine of one hundred years ago will fulfil the requirements of to day

It should be remembered that in speaking of the study of science we do not refer to getting lessons from text-books, but to the study of it in the laboratory Canned science—that obtained from books—is not wholesome brain food It is unreasonable to talk of special schools for the preliminary study of a particular profession There is no need for them if instructors would study the pupils instead of making the pupils study them The single fact that the elementary principles of chemistry and physics are "taught" in the medical schools is conclusive proof that they are not properly taught in the academic schools On this subject we have already expressed our opinion in The Journal of May 2 and June 6, 1885 In this connection we take pleasure in referring to Dr A L Gihon's Presidential Address before the American Academy of Medicine (at the same meeting at which Dr Sibbet's paper was read), the more so because he plainly shows that he does not agree with some members of the Academy in thinking that a boy's mind must be matured on Latin, Greek, mathematics and canned science

Finally, it may not be amiss to compare Dr Sibbett's letter in this issue of The Journal with some of the statements in his first paper, as in this way we may more easily see how high a valuation he sets upon science and scientific schools in education "The acquisition of knowledge and mental discipline are therefore dependent upon certain conditions

No one would think of dispensing with books, instructors and institutions" Books may be and often are dispensed with in teaching science The quotation can therefore refer only to *classical* education In the requirements for admission to medical colleges, he tells us, "classical studies are generally treated with indifference" We know that scientific studies are equally disregarded, why is not the fact mentioned? Again, "Shall we tell it in New York that the oldest university in America does not require a knowledge of the five declensions of Latin nouns for matriculation in her medical department?" That is certainly not so disgraceful as not requiring a knowledge of the elements of natural science "Another portion of our profession—possibly one fourth—have advanced as far in algebra as quadratic equations, and in geometry as the *pons asinorum* In Latin they have reached the Bucolics of Virgil, or the Jugurthine War by Sallust, and in Greek the third book of Xenophon's Anabasis Of rhetoric, logic, mental and moral philosophy they know nothing" From this it seems that he does not consider scientific principles as of any importance whatever Again, "But what shall we say of the remaining half of our profession? They have never even glanced at the academic studies referred to, and consequently they are without the mental discipline and training which these studies always bring The student must become an active agent, not merely a passive one He must work out problems in mathematics for himself, if he has not done so, he must translate foreign languages into good English, if he has not done so, he must prepare an original essay every week for four or five years, before he is properly prepared to study medicine" It seems absolutely useless to talk of scientific schools and scientific education until the papers from which these quotations are taken are retracted, and until this is done we beg to take leave of the subject

INTERNATIONAL MEDICAL CONGRESS OF 1887
PROGRESS OF ORGANIZATION

The statement in some recent medical journals to the effect that the progress of organization for the International Medical Congress of 1887 "seemed to have come to a standstill," is by no means correct, as the following facts will show

Soon after the final meeting of the General Committee on Organization appointed by the American Medical Association in September last, at which the said Committee adopted entirely satisfactory Rules

for the Congress, selected the general officers, and chief officers of the several Sections, thereby developing under their Rule Ten an independent Executive Committee of the Congress, authorized to take charge of the entire interests and further management of the organization, the said Executive Committee held a full meeting in November and organized for their work The President and Secretary General were instructed to issue a preliminary circular giving the general officers selected and the Executive Committee, together with the Rules in English, French, and German, and distribute the same both in Europe and America At the same meeting sub committees were appointed on all the more important items of unfinished business, to report at another meeting of the Executive Committee to be held in a few weeks from this time These sub committees have been quietly but diligently prosecuting their work so successfuly that at the next Executive Committee meeting there will be neither difficulty nor delay in filling all vacancies needed to make the preliminary organization of the Congress complete, and be ready to proceed directly with the preparation of the details for the final programme for the work of every department of the Congress The local committee of reception and arrangements at Washington, with Dr A Y P Garnett for Chairman, has increased its members to fifty, acting in harmony, and for more efficiency in execution, divided into seven sub-committees, with each its allotted part of the work to be done

This is a guarantee that every possible arrangement will be made for the interests and comfort of those who may attend the Congress from any part of the world, and that active efforts will be made to secure the lowest rates of travel on ocean steamers and railroads for those coming from other countries, and in regard to which timely notice will be given With the aid of the Associate Secretary-General in New York the circulars anouncing the Preliminary Organization and Rules of the Congress were freely distributed in foreign countries, and its reception was immediately followed by cordial responses, which have continued to be received almost daily at the office of the Secretary General from many of the countries of Europe, more especially from Great Britain, France, Germany and Austria, giving assurances of personal attendance, promising communications for certain Sections, and asking for further information Instead, therefore, of a "standstill," the work of preparation for the Congress of 1887 is progressing rapidly and successfully towards completion We have deemed it proper to make the foregoing statement to prevent misapprehensions, and for the general information of the medical profession at home and abroad

SOCIETY PROCEEDINGS.

CHICAGO MEDICAL SOCIETY

Stated Meeting, March 15th, 1886

THE PRESIDENT, C T PARKES, M D, IN THE CHAIR

DR ROBERT H BABCOCK made remarks on

TWO CASES OF MITRAL STENOSIS, WITH PRESENTATION OF THE PATIENTS

DR BABCOCK said that he did not intend to give any discussion of mitral stenosis, but merely desired to present a few points of interest in connection with these patients Mitral obstruction is due to a fusing together of the valves so that they project into the ventricle in the form of a funnel, which, according to many authors, is the most frequent form of stenosis, according to others, the obstruction is due to a septum like valve stretching across the opening, and called the diaphragmatic valve Owing to the obstruction to the flow of blood from the auricle into the ventricle a murmur is produced which is rolling, or blubbering in character, and, occurring during the auricular systole and previous to the systole of the ventricle, is called pre-systolic or auriculo-systolic This murmur has been graphically represented by Balfour as in some cases resembling the sound of voot rrrb, the final t or b being the sudden, abrupt first sound produced by the ventricular systole

In some cases no pre-systolic murmur, correctly speaking, is heard, only a diastolic murmur which, being loudest at the apex in the mitral area, is a mitral diastolic murmur This murmur should be differentiated from the diastolic murmur of aortic regurgitation which, in certain rare cases described by Balthazar Foster, has its maximum of intensity in the mitral area and not at the centre of the sternum

In the two cases Dr Babcock presented the murmurs differed from each other in character, in the one case the murmur being very distinctly represented by the letters voot, in the other by rrrb The doctor was disappointed at the last moment by his inability to present a third patient, a man in whom the stenosis was indicated by a mitral diastolic murmur which followed an impure first sound of heart, and both the impure first sound and the diastolic murmur were in this case audible at the lower angle of the left scapula The propagation of the diastolic murmur so far to the left is very unusual, indeed, the production of the mitral diastolic murmur is itself very rare, and is probably due to the fact that a rush of blood from the left auricle to the ventricle occurs with greater force at the beginning of the ventricular diastole than during the auricular systole, the auricle being dilated rather than hypertrophied, according to Sansom The cases were then examined by members of the Society

DR E C DUDLEY reported a

UNIQUE CASE OF VESICO VAGINAL FISTULA,

in which the entire vesico vaginal septum, the vaginal portion of the cervix, and anterior wall of the cervix to the internal os had sloughed away, leaving no

since the methods in the different schools are essentially different. He has thus placed himself in the anomalous position of recommending schools which, as he has shown, he considers objectionable. But the truth is, there is no system of education which will educate in all directions. He evades the question, which he asks, What shall a student, who desires a good education, study until he is capable of deciding what he should do in life? His statement, under this question, that educated men in all countries and for many centuries have presented and advocated a combined classical, scientific, and literary course of study as the very best that can be devised for young men who desire to enter the learned professions, is singularly inaccurate. Three centuries are not *many*, and that is a liberal allowance for the age of our classical system. In the statutes of the University of Paris of 1600 the studies in arts are defined as Latin, Greek, Aristotle's Philosophy, and Euclid. Scientific and literary studies had no part or lot in the education of that period. Inasmuch as our science of to-day can scarcely be said to be one century old, it is manifestly absurd to say that it has been advocated for many centuries. It is not less absurd to hold that the preliminary education for the medicine of one hundred years ago will fulfil the requirements of to-day.

It should be remembered that in speaking of the study of science we do not refer to getting lessons from text books, but to the study of it in the laboratory. Canned science—that obtained from books—is not wholesome brain food. It is unreasonable to talk of special schools for the preliminary study of a particular profession. There is no need for them if instructors would study the pupils instead of making the pupils study them. The single fact that the elementary principles of chemistry and physics are "taught" in the medical schools is conclusive proof that they are not properly taught in the academic schools. On this subject we have already expressed our opinion in THE JOURNAL of May 2 and June 6, 1885. In this connection we take pleasure in referring to Dr. A. L. Gihon's Presidential Address before the American Academy of Medicine (at the same meeting at which Dr. Sibbet's paper was read), the more so because he plainly shows that he does not agree with some members of the Academy in thinking that a boy's mind must be matured on Latin, Greek, mathematics and canned science.

Finally, it may not be amiss to compare Dr. Sibbett's letter in this issue of THE JOURNAL with some of the statements in his first paper, as in this way we may more easily see how high a valuation he sets upon science and scientific schools in education. "The acquisition of knowledge and mental discipline are therefore dependent upon certain conditions. No one would think of dispensing with books, instructors and institutions." Books may be and often are dispensed with in teaching science. The quotation can therefore refer only to *classical* education. In the requirements for admission to medical colleges, he tells us, "classical studies are generally treated with indifference." We know that scientific studies are equally disregarded; why is not the fact mentioned? Again, "Shall we tell it in New York that the oldest university in America does not require a knowledge of the five declensions of Latin nouns for matriculation in her medical department?" That is certainly not so disgraceful as not requiring a knowledge of the elements of natural science. "Another portion of our profession—possibly one fourth—have advanced as far in algebra as quadratic equations, and in geometry as the *pons asinorum*. In Latin they have reached the Bucolics of Virgil, or the Jugurthine War by Sallust, and in Greek the third book of Xenophon's Anabasis. Of rhetoric, logic, mental and moral philosophy they know nothing." From this it seems that he does not consider scientific principles as of any importance whatever. Again, "But what shall we say of the remaining half of our profession? They have never even glanced at the academic studies referred to, and consequently they are without the mental discipline and training which these studies always bring. The student must become an active agent, not merely a passive one. He must work out problems in mathematics for himself, if he has not done so; he must translate foreign languages into good English, if he has not done so; he must prepare an original essay every week for four or five years, before he is properly prepared to study medicine." It seems absolutely useless to talk of scientific schools and scientific education until the papers from which these quotations are taken are retracted, and until this is done we beg to take leave of the subject.

INTERNATIONAL MEDICAL CONGRESS OF 1887.
PROGRESS OF ORGANIZATION.

The statement in some recent medical journals to the effect that the progress of organization for the International Medical Congress of 1887 "seemed to have come to a standstill," is by no means correct, as the following facts will show.

Soon after the final meeting of the General Committee on Organization appointed by the American Medical Association in September last, at which the said Committee adopted entirely satisfactory Rules

for the Congress, selected the general officers, and chief officers of the several Sections, thereby developing under their Rule Ten an independent Executive Committee of the Congress, authorized to take charge of the entire interests and further management of the organization, the said Executive Committee held a full meeting in November and organized for their work The President and Secretary-General were instructed to issue a preliminary circular giving the general officers selected and the Executive Committee, together with the Rules in English, French, and German, and distribute the same both in Europe and America At the same meeting sub committees were appointed on all the more important items of unfinished business, to report at another meeting of the Executive Committee to be held in a few weeks from this time These sub committees have been quietly but diligently prosecuting their work so successfuly that at the next Executive Committee meeting there will be neither difficulty nor delay in filling all vacancies needed to make the preliminary organization of the Congress complete, and be ready to proceed directly with the preparation of the details for the final programme for the work of every department of the Congress The local committee of reception and arrangements at Washington, with Dr A Y P Garnett for Chairman, has increased its members to fifty, acting in harmony, and for more efficiency in execution, divided into seven sub-committees, with each its allotted part of the work to be done

This is a guarantee that every possible arrangement will be made for the interests and comfort of those who may attend the Congress from any part of the world, and that active efforts will be made to secure the lowest rates of travel on ocean steamers and railroads for those coming from other countries, and in regard to which timely notice will be given With the aid of the Associate Secretary-General in New York the circulars anouncing the Preliminary Organization and Rules of the Congress were freely distributed in foreign countries, and its reception was immediately followed by cordial responses, which have continued to be received almost daily at the office of the Secretary-General from many of the countries of Europe, more especially from Great Britain, France, Germany and Austria, giving assurances of personal attendance, promising communications for certain Sections, and asking for further information Instead, therefore, of a "standstill," the work of preparation for the Congress of 1887 is progressing rapidly and successfully towards completion We have deemed it proper to make the foregoing statement to prevent misapprehensions, and for the general information of the medical profession at home and abroad

SOCIETY PROCEEDINGS.

CHICAGO MEDICAL SOCIETY

Stated Meeting, March 15th, 1886

THE PRESIDENT, C T PARKES, M D , IN THE CHAIR

DR ROBERT H BABCOCK made remarks on

TWO CASES OF MITRAL STENOSIS, WITH PRESENTATION OF THE PATIENTS

DR BABCOCK said that he did not intend to give any discussion of mitral stenosis, but merely desired to present a few points of interest in connection with these patients Mitral obstruction is due to a fusing together of the valves so that they project into the ventricle in the form of a funnel, which, according to many authors, is the most frequent form of stenosis, according to others, the obstruction is due to a septum like valve stretching across the opening, and called the diaphragmatic valve Owing to the obstruction to the flow of blood from the auricle into the ventricle a murmur is produced which is rolling, or blubbering in character, and, occurring during the auricular systole and previous to the systole of the ventricle, is called pre systolic or auriculo-systolic This murmur has been graphically represented by Balfour as in some cases resembling the sound of voot rrrb, the final t or b being the sudden, abrupt first sound produced by the ventricular systole

In some cases no pre systolic murmur, correctly speaking, is heard, only a diastolic murmur which, being loudest at the apex in the mitral area, is a mitral diastolic murmur This murmur should be differentiated from the diastolic murmur of aortic regurgitation which, in certain rare cases described by Balthazar Foster, has its maximum of intensity in the mitral area and not at the centre of the sternum

In the two cases Dr Babcock presented the murmurs differed from each other in character, in the one case the murmur being very distinctly represented by the letters voot, in the other by rrrb The doctor was disappointed at the last moment by his inability to present a third patient, a man in whom the stenosis was indicated by a mitral diastolic murmur which followed an impure first sound of heart, and both the impure first sound and the diastolic murmur were in this case audible at the lower angle of the left scapula The propagation of the diastolic murmur so far to the left is very unusual, indeed, the production of the mitral diastolic murmur is itself very rare, and is probably due to the fact that a rush of blood from the left auricle to the ventricle occurs with greater force at the beginning of the ventricular diastole than during the auricular systole, the auricle being dilated rather than hypertrophied, according to Sansom The cases were then examined by members of the Society

DR E C DUDLEY reported a

UNIQUE CASE OF VESICO VAGINAL FISTULA,

in which the entire vesico vaginal septum, the vaginal portion of the cervix, and anterior wall of the cervix to the internal os had sloughed away, leaving no

bladder tissue between the inner extremities of the urethra and the points at which the vesico-uterine ligaments connect the bladder with the uterus. The only operation which seemed possible was to unite the posterior wall of the cervix uteri with the neck of the bladder. This would turn the uterus into the bladder and necessitate menstruation through the urethra. The anterior wall of the uterus could not be approximated to the neck of the bladder, but it was found, on further examination, that the mucous membrane of the bladder, if caught with the tenaculum about an inch in front of the uterus, could be drawn to the neck of the bladder and held without undue traction. The operator therefore undertook to close the fistula in this way by denuding a strip of the mucous membrane of the bladder from side to side an inch in front of the uterus, and thus he utilized that portion of the bladder between the line of denudation and the uterus, and made it a substitute for the lost anterior wall of the cervix and vesico-vaginal septum. Twenty-two silver wire sutures were employed after Sims's method. Union by first intention followed, notwithstanding the failure of the nurse the third day to keep the catheter *in situ*, which allowed several ounces of the urine to accumulate in the bladder. Notwithstanding the decrease in the size of the bladder necessitated by the operation, the patient experiences no difficulty in retaining the urine all night. The operator is not aware that another case of this kind has been previously reported.

THE PRESIDENT asked if it was not possible that some portion of the upper wall of the vagina was drawn upwards and backwards by the bladder, and what was taken to be a continuous wall of the bladder might be a part of the vagina. He had seen a case where there was a large laceration into the bladder, and the opening seemed one cavity with continuous walls, but the flap thrown backwards was post-vaginal, and it was found that this flap could be drawn up and into its position.

DR. L. C. DUDLEY, in answer to questions, said that the loss of tissue at the base of the bladder from sloughing differs from that by incision. In the latter case the ureters would perhaps be included in the excised tissue, but it is seldom that a slough of the base of the bladder in vesico-vaginal fistula, however extensive, destroys the connection between the bladder and kidneys. Even if the points through which the ureters penetrate the mucous coat of the bladder be lost, it is yet possible their openings into the bladder may be preserved, because the ureters penetrate the muscular coats nearly an inch from their normal points of opening through the mucous coats of the bladder, and run obliquely between the two coats for a distance of nearly an inch. In this case, as in many cases of loss of entire base of bladder reported by Emmet, the openings of the ureter were on either side at the very margins of the fistulous opening. The operation was performed at Morton, Ill., in the presence of Dr. Harris of that place, and Dr. Mansfield, of Metamora. Dr. Parkes's surmises with reference to the vaginal wall could hardly be correct because this, together with the anterior wall of the cervix uteri up to the internal os, had sloughed away. His surmise might be correct with reference to certain tissues between the bladder and cervix uteri which might have retracted and become adherent by inflammation, so as actually to form a portion of the bladder wall. Moreover, there is always a very decided difference in color and appearance between vaginal and bladder membrane, and the membrane in this case was to all appearance like that of the rest of the bladder, and to the touch gave the sensation of a thin wall. Dr. Baker, of Boston, reports a case similar to this in that he introduced sutures into the bladder tissue, but so close to the cervix uteri as not to draw down any portion of the interior of the bladder, to be used as material in place of the lost vaginal wall.

DR. W. L. AXFORD reported

A CASE OF REMOVAL OF THE ENTIRE LOWER JAW THROUGH THE MOUTH.

Harry T., aged 5. Admitted to St. Joseph's Orphan Asylum in November, 1885. It was noticed that his mouth was frequently swollen and sore. Child very much emaciated. In January, 1886, he had measles. Tedious convalescence followed. Came under observation about February 1. Weak and thin. Lower part of face very much swollen. Breath offensive. Symphysis of jaw bare. Could not examine further at this time. Pulse 120 to 130. Put the child on supporting treatment, hoping to get him in condition for an operation. No improvement at the end of two weeks. February 16 the patient was anæsthetized and the mouth explored. Found the jaw on either side stripped of its periosteum back to the masseters. Determined to attempt removal through the mouth, as any cutting operation involving the loss of much blood would have been fatal at once. Divided the jaw on either side of the symphysis with bone pliers and thus removed a large portion of the body. Seizing the remaining pieces with sequestrum forceps and making moderate traction, they were easily enucleated by the index finger of the left hand. Not more than a tablespoonful of blood was lost. Patient rallied well. Some reaction on second day. On third day the pulse had dropped to 116, and with exception of a swollen parotid on the left side the child was in better condition than before the operation, so much so that a recovery was confidently predicted. A severe attack of diarrhœa occurring on the morning of the fourth day was followed by death in thirty-six hours.

DR. ARNOLD P. GILMORE exhibited a patient on whom he had performed an operation for

SYMBLEPHARON OF THE LOWER LID,

due to a burn by molten iron, and in which three plastic operations had been unsuccessfully performed. Nine months previously the entire lower lid from external to internal canthus was adherent to the eyeball covering almost the entire cornea. This triangular-shaped tissue was covered by a pale membrane of cicatricial tissue. The operator first detached the lower lid and transplanted the conjunctiva of a rabbit. For six weeks the operation was apparently successful, but after an absence of two months from the city he found the lid was again becoming adherent. Six weeks previously Dr. Gilmore made a thorough dissection, freeing the lid and making a deep cul de sac, leaving the upper half of the eyeball covered by mucous membrane and the lower half bare. A semicircular band of conjunctiva, one third inch wide, close to the cornea above, leaving a bridge of tissue at each end. This band was dropped into the cul de sac below and carefully stitched to the ball. A semicircular plate of silver long enough to fill the space between the external and internal canthi, with two holes at the circumference, one half inch apart, threaded with silver wire, was dropped into the cul de sac to prevent adhesions, and fastened by bringing the wires through upon the face and fastening them by small lead plates and perforated shot. For this operation Dr. Gilmore claimed priority. The object of the operation was neither to improve the appearance of the eye nor to restore vision, but to relieve the irritation of the other eye, by allowing coordinate movements of the two eyes. There was enough clear cornea left to make an artificial pupil in case the patient ever lost his well eye. There was little reaction, and at no time much pus, while the well eye has grown stronger in spite of the presence of the plate.

Dr. Tilley thanked Dr. Gilmore for showing this case, but thought that if the Doctor were to go out of town again for two months as in the first instance, he would find at the expiration of that time the conditions relatively very much the same as on his return after the first operation. He thought there was little fundamental advantage likely to be associated with the operation, as he thought that in a short time the wire and plate would cause a certain amount of atrophy of the intervening tissue and the plate be forced up out of position, making the operation of no avail. If he was so unfortunate personally as to be placed in a similar position, he would have his eye enucleated.

Dr. E. L. Holmes thought it unwise to say that a certain thing could not possibly be accomplished, but he had been through the experience of putting in plates, and seeing it done, and never saw one permanently successful. It is different with a very narrow symblepharon in which the globe and eyelid are grown together, where by dissection and transplanting the mucous membrane excellent results may be attained. He thought the plate would irritate the cicatricial tissue and cause it to be very much thickened, and after a few months, or weeks even, when everything is removed, there will be the same tendency to creep over the cornea and make adhesions with a broad union. He thought it absolutely impossible to get an artificial eye to fit. A very small eye might be used and temporarily make it appear that the patient was better off, but that small eye will often irritate and cause the cicatrix to increase.

The President thought this case one of the same category that is so troublesome to the general surgeon, the improvement of deformities from cicatrices of all kinds, in which relief comes only in the way that Dr. Dudley has applied in gynecology, after the divided cicatrix has been separated as widely as possible, by drawing together the healthy skin or tissue between the two ends of the divided cicatrix. This method has long been in use in general surgery. So far as his experience went the application of any foreign body between these divided surfaces has never been followed by success, so far as prevention of contraction goes.

The President presented an

ENCAPSULATED SARCOMA OF THE THIGH.

It had been in alcohol for some time, and was reduced about one third in size. It had grown the full extent shown in three months, and was removed from an old lady aged 69. It was found growing upon the posterior part of the upper portion of the thigh, was a firm, smooth tumor to the touch, and as far as external manipulations determined could not be distinguished positively from other parts of the surrounding tissues. He could not determine whether it was or not attached to the bone, but from external appearances it was diagnosticated to be of a malignant type. The external surface was crossed by a large number of varicose veins. After removal it was shown to be a sarcoma. The interesting point was the rapidity of its growth. He thought it a singular coincidence that about a year previous he had removed a similar tumor from the upper portion of the left arm of an old man of 72 years, which had also grown to the full size in three months. Upon exposing the tumor a perfect capsule was reached, and it was easily enucleated from its bed.

GYNÆCOLOGICAL SOCIETY OF BOSTON.

Annual Meeting, January 14, 1886.

The President, Henry O. Marcy, M.D., in the Chair.

H. J. Harriman, M.D., Secretary.

The following

NEW MEMBERS

were elected: Drs. Helen L. Betts, Emily Pagelsen, Grace Wolcott, Lena V. Ingraham, N. O. B. Wingate, A. E. McDonald, and J. E. Kelley.

The following were elected

OFFICERS FOR THE ENSUING YEAR:

President, Dr. H. O. Marcy, Vice President, Dr. H. C. White, Secretary, Dr. H. J. Harriman, Treasurer, Dr. W. Symington Brown, Pathological Committee, Drs. E. W. Cushing, A. P. Weeks, and H. O. Marcy, Nominating Committee, Drs. H. M. Field, E. C. Keller, and C. W. Stevens.

Stated Meeting, February 11, 1886.

The President, Henry O. Marcy, M.D., in the Chair.

Dr. A. L. Norris read a paper on

CERTAIN PATHOLOGICAL CONDITIONS INCIDENT TO THE FŒTUS,

illustrated by a series of cases.

Case I.—Mrs. S., married, age 26 years. Mother of one child. Last menstruation, April 5, 1885.

Had no symptom of pregnancy except cessation of menses During previous pregnancy had suffered from nausea and vomiting Was examined August 1, 1885, and appeared to be about three months pregnant She did not think that she could be pregnant, but decided to wean her child, which was 13 months old She was examined again on Oct 22 Had appearance of being pregnant at four months No motion, no fœtal heart sounds Abdomen was not much larger than at August examination In the meantime she had been examined by other physicians, who thought a uterine or ovarian tumor to exist January 4, 1886, the abdomen seemed less in size than at October visit On January 6 she was delivered of a 4½ months fœtus which was mummified and enclosed in membranes Fœtus, membranes and placenta were extracted in one mass nine months from date of last menstruation The usual amount of hæmorrhage followed delivery No odor Convalescense normal

Case 2 was similar to case 1 A fœtus was carried five months without symptoms other than cessation of growth Cases 3 and 4 were cases of triplets In case 3 the mother had had eight single births previously One boy and two girls were born at a quick and normal labor Mother nursed the three children until they were several weeks old One girl and the the boy died when six weeks of age The other girl still lives and is in good health In case 4 a primapara was delivered of two healthy girls and a still born boy The fœtus of the boy was of three months development, and was mummified Both girls are alive and well

Case 5 was one of spontaneous amputation *in utero* of both arms at the shoulder During the last four months of gestation the mother suffered from intractable chronic diarrhœa and from vomiting Boy is still alive and well, and uses his toes with almost as much facility as other boys use their fingers

Dr H M Field, in discussing Case 1, asked Dr Norris if he regarded pregnancy as a bar to further nursing He called attention to a series of articles by Dr Dolan on the influence of drugs upon lactation, in which that writer takes exception to the popular opinion upon this point He found that the milk of pregnant women was not impoverished, and concluded from this fact that pregnancy was not a contra indication to further nursing in a majority of cases In France the laws forbid a pregnant woman's acting as wet nurse, upon the ground that the milk of such women is inferior both in quantity and quality, and thus the health of the nursing child is in danger

Dr Norris, in reply to Dr Field, said that in his opinion a pregnant woman should not nurse a child Abortion was likely to follow such a practice, and the health of the child was endangered Children nursed by pregnant women were invariably ill nourished, as proven by loss of color and flesh

Dr Warner took exception to Dr Norris's conclusions in regard to his first case Dr Warner thought it far more probable that the fœtus had continued to live up to the time of its expulsion, but through some vice of nutrition had ceased to grow, than that it had died during the early months of gestation and been retained until the ninth month

Dr A P Clarke described several cases which were similar to Dr Norris's first case

Case 1 —Mrs B, 38 years old, multipara Miscarried three times Menses regular until last August, when they disappeared She suspected she was pregnant, though no morning sickness or other usual symptoms of pregnancy appeared A fœtus was expelled and the placenta found to be fatty Amount of amniotic fluid was small Fœtus was buff colored, somewhat flattened, and measured seven inches in length

Case 2 —Mrs W, 36, multipara When first seen was suffering from severe uterine hæmorrhage Vaginal examination revealed a cyst presenting, which was ruptured by the examining finger A blighted fœtus, three inches long, which had undergone mummification, was removed Placenta had been attached until time of expulsion, and fresh hæmorrhage followed its removal Menses had been absent for eight months preceding the expulsion of the fœtus At first patient had suffered from morning sickness, but during last five or six months had had no such trouble The breasts had increased somewhat in size Patient had grown stouter, but abdomen had not increased in size during later months of gestation

Case 3 —Mrs W, 34, multipara Labor normal and female child born at term Child well developed On the removal of the placenta a flattened and mummified fœtus was expelled Was of a buff color, six inches in length, enclosed in membranes

In reply to Dr Warner, Dr Clarke said that mummification usually takes place in cases where the fœtus dies, the fluid elements of the body are reabsorbed, and the membranes are unruptured If, however, the membranes are ruptured and the air enters, putrefaction takes place

Dr E W Cushing said that there was nothing impossible about a fœtus being carried for months after its death, as claimed by Dr Norris There are cases on record which seem to prove it beyond a doubt

Dr M D Church described the case of Mrs M, who, at nearly full term, received a fright and fall in a horse car on March 26, 1883 Was delivered of a still born fœtus, twenty-two inches long and fully developed Funis was drawn tightly about the neck of the child twice The epidermis slipped on all parts of the body He raised the following questions 1st How long must a fœtus be dead *in utero* before the skin will slip? 2d Was the tight funis the cause of death? 3d *Was the fall in the horse-*car the cause of the tightening of the cord?

Dr Keller described the following case Mrs S, 35 Five children at term Miscarried five times on account of lacerated cervix The fifth time had been pregnant eleven weeks when she had "a profuse flow of blood with clots" She was carefully examined by a physician, who concluded that the uterus was empty The flow continued nine weeks when an ovum entire with fœtus 1½ inches long was expelled No odor The product of conception seemed perfectly healthy when cast off

Dr Helen Betts, in referring to the question of a woman nursing when pregnant, thought that few women were able to nurse a baby and carry a fœtus at the same time without injury either to themselves or to those in their charge In most cases it seemed wise to withdraw a part of the burden by directing that the child be weaned

The President, in commenting upon the specimen presented by Dr Norris, said it was one not only of exceptional interest, but represented a whole series of placental changes which, until recently, had been but little understood The late distinguished Professor G B Ercolani, of Bologna, rendered a service to the profession of incalculable value in his studies of placental development, and his demonstrations, after long and patient research in the large field of comparative as well as human anatomy, are of the first importance to science He shows conclusively that fœtal alimentation in all mammals is carried on by a single, universal law of physiological modality, that the fœtal villus is simply a means of absorption of nutritive material, which is, in all cases, furnished by a glandular, secretive organ of maternal development The expression of this anatomical type is of the widest variety, and in woman, in the fully developed placenta, reaches a complexity of form confusing in the highest degree The chorial villi, which during the earlier months of pregnancy are developed over the entire surface of the chorion, are composed of two parts, internal and external The first, which was called by Robin chorial tissue, and by Virchow mucous or myxoma, is in direct contact with the chorion, the latter, which consists of an epithelial envelope entirely surrounds it The villi, at the placental site, increase normally in number and volume Elsewhere, they are arrested in their growth and disappear by atrophy and fatty degeneration The decidua is, at first, a single bed of cells of new formation, and afterward proliferates to a remarkable degree at the placental site—the decidua serotina The epithelial covering of the placental villi is perceived same time after they have been enveloped by the cells of the serotina but disappear at an early period Not seldom, in case of so called mole pregnancy, the choroid villi, which should atrophy, increase in volume Under these conditions the external epithelium does not atrophy, but proliferates and has been mistaken for the internal surface of the epithelium furnished to the placental villi from the modified cells of the serotina At the later stages of pregnancy, the examination of any remaining choroid villi shows them still covered with an epithelial layer, while the placental villi have lost this envelope and are formed only of the fundamental myxomatous tissue which encloses the fœtal vessels, and thus the external parenchyma of the villi is in contact with the internal epithelium of the surrounding glandular organs

Pathological conditions, such as are represented in this specimen, where the fœtus has been for some time dead and the placenta has remained undisturbed in its attachments to the uterus, give confirmatory evidence of the truth of the demonstrations of Ercolani I have frequently observed, microscopically, the close contact of the choriol villi with the epithelial covering of the maternal vessels when the placenta has been undisturbed in connection with the uterus for a considerable period after the death of the fœtus The choriol villi have become shrunken, and are easily separated from the decidual sheath, the cells of which have undergone active proliferation In one instance this was observed to have taken place and continued in a stage of active development, in a portion of a placenta removed three months after the expulsion of the fœtus

Dr Marcy was glad to have the attention of the Society called to this class of specimens They are of interest from the practical side of observation and often involve danger to two lives The pathological committee of the Society will gladly investigate and report upon any specimens which may be forwarded to them

MEDICAL SOCIETY OF THE DISTRICT OF COLUMBIA

Stated Meeting, February 17, 1886

Vice-President, John B Hamilton, M D, in the Chair

T E McArdle, M D, Secretary

Dr C V Boarman read a paper on

JAUNDICE FOLLOWING CONCUSSION OF THE BRAIN

On December 30, 1885, I was called to see J B, age 30, married, a laborer at the Monument, who, whilst assisting at some mechanical work, lost his balance and fell a distance of thirty feet, striking upon his head, tearing the scalp from and exposing for several inches square the vertex of his skull, he also bruised and lacerated his forehead in several places His body and limbs were also bruised I found him at his home (to which he was brought in a carriage), in a sitting posture, apparently dazed, would answer questions in monosyllables after their repetition in a loud voice, was spitting blood and his nose bleeding

I washed the semi detached scalp in carbolized water and reapplied it in its proper place, holding it there by means of a stitch and adhesive plaster, ordered him to be put to bed at once and lotions applied to his face and other bruised parts About six hours after a messenger came to my office to ask for something to relieve Mr B's sick stomach, and also notified me that he had vomited about a pint of coagulated blood, and that there was still considerable retching and nausea I at first thought that the above might be caused by compression, but as I gave the injury a very thorough examination at the time I saw it and discovered nothing of the kind, I concluded that it was due partly to the concussion, and also the blood which had run down the œsophagus from the posterior nares, as there was considerable epistaxis I ordered ice, lime water and milk, also some ingluvin, and after a few hours bromide potass in solution, as there was considerable excitement, groaning and jactitation

December 31 Mr B was quietly resting upon

Had no symptom of pregnancy except cessation of menses During previous pregnancy had suffered from nausea and vomiting Was examined August 1, 1885, and appeared to be about three months pregnant She did not think that she could be pregnant, but decided to wean her child, which was 13 months old She was examined again on Oct 22 Had appearance of being pregnant at four months No motion, no fœtal heart sounds Abdomen was not much larger than at August examination In the meantime she had been examined by other physicians, who thought a uterine or ovarian tumor to exist January 4, 1886, the abdomen seemed less in size than at October visit On January 6 she was delivered of a 4½ months fœtus which was mummified and enclosed in membranes Fœtus, membranes and placenta were extracted in one mass nine months from date of last menstruation The usual amount of hæmorrhage followed delivery No odor Convalescense normal

MEDICAL SOCIETY OF THE DISTRICT OF COLUMBIA

Stated Meeting, February 17, 1886

Vice President, John B Hamilton, M D , in the Chair

T E McArdle, M D , Secretary

Dr C V Boarman read a paper on

JAUNDICE FOLLOWING CONCUSSION OF THE BRAIN

On December 30, 1885, I was called to see J B , age 30, married, a laborer at the Monument, who, whilst assisting at some mechanical work, lost his balance and fell a distance of thirty feet, striking upon his head, tearing the scalp from and exposing for several inches square the vertex of his skull, he also bruised and lacerated his forehead in several places His body and limbs were also bruised I found him at his home (to which he was brought in a carriage), in a sitting posture, apparently dazed, would answer questions in monosyllables after their repetition in a loud voice, was spitting blood and his nose bleeding

I washed the semi detached scalp in carbolized water and reapplied it in its proper place, holding it there by means of a stitch and adhesive plaster, ordered him to be put to bed at once and lotions applied to his face and other bruised parts About six hours after a messenger came to my office to ask for something to relieve Mr B 's sick stomach, and also notified me that he had vomited about a pint of coagulated blood, and that there was still considerable retching and nausea I at first thought that the above might be caused by compression, but as I gave the injury a very thorough examination at the time I saw it and discovered nothing of the kind, I concluded that it was due partly to the concussion, and also the blood which had run down the œsophagus from the posterior nares, as there was considerable epistaxis I ordered ice, lime water and milk, also some ingluvin, and after a few hours bromide potass in solution, as there was considerable excitement, groaning and jactitation

December 31 Mr B was quietly resting upon his back in bed upon my arrival, perfectly conscious, no headache or sick stomach, but still spitting up blood He stated that after vomiting copiously the night before, he felt much better, became perfectly conscious and passed a good night The vomiting was no doubt as much dependent upon the blood which had run down his œsophagus as upon the concussion of the brain I examined his wounds and found them doing well, very little suppuration, the scalp wound inclined to unite The entire head, face, and even the neck was very much swollen, looked like it was puffed up with air, but no redness or tenderness, in fact, no positive symptom of erysipelas His sclerotics were congested and effused, the surrounding parts black from bruises He complained very much of soreness about his knees and shoulders, which were no doubt struck by projecting beams during his descent

January 1 Upon visiting Mr B , to my astonishment I found him intensely jaundiced, his sclerotics stained, urine loaded with bile pigment, and all other symptoms indicative of icterus I never saw a person more changed in appearance, being in health a very tall, thin man, his features sharp and cheek bones prominent, his present condition was such that he was hardly recognizable, as his face was terribly swollen and as yellow as saffron, the bruises and lacerations of course adding to the above abnormal appearance I removed the stitch from the scalp wound, which had united by first intention His other injuries notwithstanding his jaundiced condition, were doing well, he was still spitting up some blood, but not enough to cause any alarm I ordered a mercurial purgative, after the action of which I placed him upon nit muriatic acid dilut , at the same time, of course, regulating his diet, forbidding the fats, oils, etc The purgative acted well, bringing away a large amount of black grumous matter, no doubt partially digested blood and fæces He felt considerably relieved after his bowels acted, and left the bed

January 3 His condition was very much improved, the jaundice rapidly disappearing, and the swollen and bruised parts resuming their normal condition I did not see Mr B again until January 5, which was my last visit, as the jaundice had disappeared, and his various injuries were doing well, he was up and anxious to resume his work

I look upon the above case as rare, as in the majority of cases the physician is able to trace the disease to obstructions either existing in the intestinal canal or common duct, whereas in the above the solution of the difficulty is hard, unless we accept the theory advanced by Murchison, that concussion of the brain produces jaundice by interfering with or deranging the normal metamorphosis of bile by nervous influences Virchow mentions a form as hæmatogenic, that is, formed in the blood or taking its origin there Ponfick assigns as a cause violent mental conditions, *as for instance anger etc Murchison speaks of the* case of a soldier who became jaundiced because he was restrained from wreaking his vengeance on a comrade who had angered him

M Rendu records the case of a woman aged 25 years, convalescent from puerperal peritonitis, who became jaundiced within three hours after an unsuccessful attempt to catheterize the bladder, the skin remained yellow for four days and the urine contained bile pigment one day longer Its sudden onset and rapid disappearance are in favor of its being of neurotic origin Another case of interest having a remote origin or cause is mentioned by Dr Boucher in the *London Lancet*, July, 1884 A child aged 2 years sat down in a pail of hot water in which there was dissolved a quantity of soda The scalding was confined to the nates, on which there were two large blisters, they were treated by the usual methods On the tenth day after, there was abdominal tenderness with pain, high temperature and diarrhœa, the urine contained bile pigment, sclerotics and skin stained, in a word, a well marked case of jaundice It lasted three or four days, and then subsided This case was no doubt owing to inflammation extending to the mucous membrane of the common duct, causing an obstruction to the outward flow of bile, which in turn was followed by jaundice

It is frequently very difficult to assign a cause for jaundice, as its appearance at times is so eccentric, for instance, the jaundice of pyæmia, and those forms of the disease resulting from the narcotism of chloroform, and other forms of intoxication It also occasionally complicates pneumonitis I think the case just reported by me was due to neurotic influences, as its appearance and disappearance were so sudden Besides, I examined his urine by the usual methods, and failed to find the biliary acid, which, according to Dr G Harley, is proof that no obstruction existed, as he adopted the theory which had been advanced, "that the liver manufactures the bile acids, while it merely excretes the bile-pigment "

Dr A Y P Garnett said that jaundice is often due to traumatism Although he had no personal experience with the disease resulting from such a cause, yet the journals frequently contain reports of similar cases Nervous influences operate in a great variety of ways Some women suffer from jaundice during the period of the menses Some reflex irritation traceable to the uterus or ovaries produces an icteroid condition which disappears with the cessation of the menstrual flow We know that the presence of the infant seeking nourishment will produce an increase of maternal milk The appearance of food causes a secretion of saliva Not only quantitative but qualitative effects follow mental emotions Passion has a deleterious influence on normal secretions Fear had turned turned hair gray almost instantaneously Dr Garnett also spoke of jaundice following the bite of serpents

Dr J Ford Thompson had no experience with jaundice as a sequence of concussion of the brain He had seen icterus follow injuries about the skull, and he had seen the yellow discoloration of pyæmia and septicæmia, but he did not consider this condition pathological jaundice It is different from a jaundice caused by an impediment to the excretory ducts or by a catarrhal condition In such cases there would be an absorption of bile after its manufacture by the liver When we get to explaining things by nervous shock we do not get much satisfaction

Dr Boarman contended that jaundice may be a symptom of nervous derangement In this case he found bile pigments and biliary salts in the urine It looks, of course, as if an obstruction existed The patient had headache and nausea, both symptomatic of jaundice There was at no time even a suspicion of pyæmia or septicæmia The pulse was slow, but that condition is common in jaundice Murchison says that nervous influences can and do produce jaundice

Dr Garnett said that the metabolic activity of the hepatic cells in the production of bile is in direct proportion to the plus or minus degree of blood pressure in the liver Any agent or cause disturbing the normal physiological equilibrium of blood pressure in that organ directly affects the secretion of bile It has been shown that a section of the splanchnic nerves causes immediate dilatation of the hepatic veins, followed by a diminution of arterial blood pressure and increased flow of blood into the portal veins It is easy then to conceive how readily causes disturbing the normal functions of the nerves supplying the liver, and especially the great sympathetic, whose filaments supply the vaso motors of the hepatic arteries, may affect the secretion and diffusion of bile

Dr Boarman said that Budd concurred in Boerhaave's and Morgagni's idea, with the exception that no bile acid was found in the blood of the portal vein Prof Freidrich states that bile acid taken from the liver by blood of hepatic vein, and also absorbed from bowel, etc, undergoes in the blood a change Bile acids converted by oxidation, a normal metamorphosis, into taurin, are found in healthy lungs, and taurin and pigment are voided in the urine

Dr A F A King inquired whether the body was examined all over? If the discoloration was general? If there was bile in the stools? He thought the discoloration resulted probably from bruising He said that it was important to determine whether a yellow coloration of the surfaces is really due to the principle of the bile, and mentioned the true jaundice of the new born, and its spurious counterpart

Dr Boarman had examined the body generally but not the abdomen The urine, he repeated, contained the biliary salts, the fæces were scanty, and the color of dog's dung

Dr H D Fry asked on what symptoms the diagnosis of concussion of the brain were based?

Dr Boarman repeated the symptoms mentioned in his paper

Dr Fry thought it was important to have examined the abdomen for possible injury

Dr Boarman said that he had mentioned such a possibility in his paper

Dr J B Hamilton said it seemed the literature had been hastily treated The autopsies made by Valsalva had not shown any intimate relation between concussion of the brain and hepatic abscess Chelius says liver abscess and jaundice are common as late symptoms Ballingall, Guthrie and Gross also mention it Dr Hamilton thinks the only explanation of its production has been that it is due to an irritation of the floor of the fourth ventricle and by the pneumogastric nucleus He agrees with Dr Boarman that it is a rare but long recognized condition Duret's examination showed extravasation in the fourth ventricle in a great many cases of concussion

Dr King could not see the connection between a jaundice resulting from old liver disease, as abscess, and the acute symptoms described in the paper

Dr Hamilton spoke in general terms, and in reply to Dr Boarman said he thought that nervous jaundice, like diabetes mellitus, might be produced by compression in the fourth ventricle due to extravasation

DOMESTIC CORRESPONDENCE

LETTER FROM NEW YORK

(FROM OUR OWN CORRESPONDENT)

The Bellevue Commencement—The Funeral of Dr Flint—The Death of Dr S O Vanderpoel—The University Commencement

The commencement of the Bellevue School, which came off on the evening of March 15, was the saddest that this, or probably any other medical college, ever had The week before had been buried the accomplished and popular young Demonstrator of Anatomy, Gaspar Griswold, and at the time of its occurrence the mortal remains of the immortal teacher and writer, Austin Flint, lay in their coffin awaiting the funeral services of the morrow Under the circumstances the exercises were naturally of a memorial character, instead of the festal nature usual on such occasions They were entirely private, being held in the lecture room of the Carnegie Laboratory, connected with the college, instead of some such place of amusement as the Metropolitan Opera House or the Academy of Music, and the building was elaborately and tastefully draped in the emblems of mourning It was indeed a most affecting event In his remarks to the graduating class, which numbered 140, the President, Dr Isaac E Taylor, spoke in feeling terms of the great bereavement of the college and the profession, and the eminent physiologist, Dr John C Dalton, now President of the College of Physicians and Surgeons, paid a most touching and eloquent tribute to the dead Professor

The funeral services, which were held Tuesday, March 16, at Christ Church, of which Dr Flint was a member, were of the greatest possible simplicity, and there were no pall bearers The church was completely filled with the Faculties and students of Bellevue and the other medical schools, representatives of the New York County Medical Association, the County Society and the Academy of Medicine, and citizens generally, and among those present were many distinguished men of other callings, as well as a number of well known physicians from other cities At the head of the coffin, beside which stood, during the whole service, the faithful negro servant of Dr Flint, was a large and beautiful broken column, rising from a floral base, which was the offering of the

County Medical Association, and afterwards the flowers composing it were distributed amongst the patients in the medical wards of Bellevue Hospital, which the deceased had attended so long and faithfully and with signal benefit to the profession and suffering humanity

It was before the County Association, which was a society especially cherished by Dr Flint, that he read his last paper in public, that on "The Elements of Prognosis in Bright's Disease," which was published in THE JOURNAL of January 9 last On Sunday, the day following his death, a special meeting of the Executive Committee of the Association was held at the house of the President, Dr Leale when the memorial which has already been published was adopted, and it was determined that the next meeting of the Society, which will occur April 19, should be exclusively devoted to commemoration exercises in his honor It is expected that several of his friends and former colleagues in the different cities where he resided and won for himself not only distinction, but the sincere esteem and friendship of all his professional brethren, will be present on that occasion to render their tributes to his memory At a meeting of the Commissioners of Charities and Corrections which was held on the following day, resolutions of sympathy were also adopted, in which special attention was called to the fact that Dr Flint had been connected with the Department as visiting physician to the hospitals for twenty five years His loss is indeed an irreparable one

On the day preceding Dr Flint's death occurred that of another of the most distinguished physicians in the city and State, Dr S Oakley Vanderpoel It will thus be seen that death has of late been very busy among the eminent men of the profession here, within a few short weeks no less than four having been called away from their labors, Drs Post, Griswold, Vanderpoel and Flint While Drs Flint and Griswold were connected with the Bellevue school, Drs Post and Vanderpoel belonged to the University, the former being Emeritus Professor of Surgery and President of the Medical Faculty, and the latter Professor of Public Hygiene

The forty-fifth annual Commencement of the University Medical School was held at the Academy of Music on the 6th of March, when the degree of M D was conferred on 173 graduates The class were fortunate in having to address them the Hon Wayne MacVeagh, of Pennsylvania, who is everywhere known as one of the most attractive speakers in the country In the course of his remarks he said "If I were called upon to indicate as marvellous a change as any that has come over the knowledge of men in my time, I would say that it was the difference between the well educated and well equipped physician when I was born, and the man of the same relative rank and acquirements in his profession to day In almost every department of medical and surgical knowledge advancement has been made which has substantially revolutionized the art of healing and alleviating the diseases of men, and of prolonging human life" Later on he remarked "And charity is the crowning glory of your profession I have known a distinguished surgeon to leave the bedside of a sick President and make an exhausting journey in order to relieve the sufferings of an unfortunate person whose only possible means of recompense was gratitude"

P B P

ACADEMIC STUDIES IN RELATION TO MEDICINE

TO THE EDITOR OF THE JOURNAL

Dear Sir —In this communication I propose to use the words "academic studies" in a general sense, as we may have occasion to use the words medical studies in a similar sense By the former we understand those studies which are pursued in our common schools, high schools, military and naval schools, normal schools, academies, classical, scientific and literary schools, usually known as colleges How many of these studies should be taken up by the student prior to the study of medicine, and how much time should be spent upon each of them, are questions which can only be answered by educated men of large experience Those who have never faithfully pursued the study of mathematics, or languages, or the natural sciences, for a series of years, are not in a position to judge of their relative value as so many means of mental discipline or education Hence, they have no right to express an opinion on the subject, any more than a non medical man has a right to express an opinion in a case of pneumonia or syphilis Other questions which imply a partial or a total exclusion of these or other branches of study from the curriculum of an academic course must be answered by the same kind of authority Any new theory of preliminary education, advocated by a single profession or by a few men in a profession is scarcely worthy of serious consideration The older methods may be somewhat modified to suit the age in which we live, but we are not moving so rapidly than we can afford to abandon the experience of our fathers in any department of activity, much less in the slow processes of educating the human mind

If any one should ask where an expression of sentiment on the points mentioned or referred to may be found, we would say, that the statute books of all civilized nations (our own country being the exception) contain statements which cannot be misunderstood The minimum requirements for matriculation in the theological, law, and medical schools of all European countries, the Canadian provinces, the South American States, and Mexico, consist in knowledge of the higher mathematics, at least three languages, belles lettres, mental and moral philosophy and the natural sciences Higher attainments are encouraged, and other studies are often pursued which are not required by law The medical profession in the United States, whatever may be said to the contrary, cannot afford to occupy a lower plane than that of the profession in other great nations In the direction of mechanical inventions we may have surpassed others, being stimulated by our potent laws, but this is no evidence that we can invent a better method of educating professional men

The limited space at my disposal requires me to be brief, and therefore I will confine myself to two or three additional paragraphs

1 Our profession has thus far been under the necessity of making use of such academic institutions as the people of our numerous States have provided, and as far as it is possible for us to foresee, we will always be under the same necessity We may, as a profession, control, in some measure at least, our medical schools, because there is no other class of citizens specially interested in them Our military and naval schools, schools of design, normal schools and agricultural schools may also be regulated to suit the limited number of students who apply for admission, but no simple profession is likely to gain so great an ascendency in our country as to control the curricula of our numerous classical, scientific and literary institutions, about 300 in all, or to dictate what branches should be introduced and what excluded The fact is, that in nearly all of them, the student has the choice of two or three courses of study, and there seems to be very little more needed to make them complete The religious denominations which have very generally supervision over them have very generously provided elective courses of study for those who do not desire to study theology, and many whose sons propose to study law insist, that they shall continue all through the junior and senior years, in the course in arts which they believe to be the best suited for mental discipline A respectable number, though certainly not so large, enter upon the study of medicine with the degree of bachelor of arts To suppose that the medical profession, in the United States which has ignored every standard, academic and medical, would support special schools with a fixed and limited curriculum is folly, and we do not hesitate to say it Those who have energy to spare may waste it on such an issue, but we could not encourage them to do so People generally place their sons in the care of those whose religious sentiments are in harmony with their own, if they cannot find a school in the neighborhood I have now answered the question, *Where* should a student who desires a good education, prepare for the study of medicine? and I proceed to answer with equal brevity, another question not less important

2 *What* shall a student, who desires a good education study until he is capable of deciding what he should do in life? This is not only an important question for every student to solve, but one which the faculties and trustees of our higher educational institutions are required to consider in all its bearings For the parent to decide what shall be the life work of his son before he has reached his majority would be as unwise as to give him full possession of his inheritence during his minority, and any system of education which would require the son to make so important a decision while yet in his minority, is false We have all seen the minister in the pulpit, the attorney at the bar, and the medical doctor make a failure of life, and we have said, they have mistaken their calling It is not sufficient to have merely an education—that is, a knowledge of angles and circles, Greek and Latin verbs, syllogisms and the laws of chemistry and biology The student must have a natural fitness for his calling A life work must have some charm about it, to compensate for the annoyances incident to professional work, or disappointment and failure will result It is plain that the student is not in a position to make so important a decision until he has reached his twentieth or twenty-first year, and even then he may make a fearful blunder, nor is the parent able to assist him For the pulpit and the bar he should be an easy writer and a fluent speaker, he should have a clear voice and a pleasant address For a successful study and practice of medicine, he should have a decided inclination in the direction of the natural sciences, especially biology combined with patience, self possession and sympathy for mankind A protracted course of academic study gives the student an opportunity to study himself He will find, especially in the combined classical, scientific and literary course, opportunities to test his fitness for a place in the learned professions which he will not find in any other In this course he is left entirely free, to study his mental capabilities and pecularities, and the indications of Providence With these advantages, if he has chosen medicine, he will make more progress in one year than others will in two or three years, and he will not be constantly goaded with the thought that he is entirely ignorant of many branches of study which adorn the educated world These and similar considerations have induced educated men in all civilized countries and for many centuries to present and advocate a combined classical, scientific, and literary course of study as the very best that can be devised for young men who desire to enter the learned professions

In conclusion, allow me to say that it ill becomes the medical profession in our country to complain of our higher literary institutions, much less does it become us to speak of them in a disrespectful manner In most of these schools instruction is gratis, or nearly so, besides it is entirely optional with the student whether he pursues one course of instruction or another When our medical schools command as much respect as our academic institutions, they also will be liberally endowed A high standard and an honorable policy will alone secure the confidence of those who have money to spare R. LOWRY SIBBET, M D

Carlisle, Pa , March 7

NECROLOGY

AUSTIN FLINT, SR , M D , LL D

Died at his residence in New York, on Saturday, March 13, AUSTIN FLINT, SR , of cerebral apoplexy He was stricken about midnight on Friday Two or three weeks before he was called to Tarrytown to an important consultation, and on returning to the city found a pressure of business among his own patients He was very much exhausted when the hour for a lecture at Bellevue arrived, but insisted on delivering it even while complaining of the burden he felt it For several days after this strain his friends noticed that he seemed depressed and nervous, but he soon recovered his wanted energy, which was marvellous for a man of his years The last lecture for the term a few days ago was an hour long, and he followed it with a quizzing exercise which would have done credit to a professor of 40 He attended the examinations which were concluded on Friday, went to the Faculty meeting on Friday night, which lasted till a late hour, and was driven home apparently in the best of health and spirits Very soon after reaching his home he was taken ill Dr E G Janeway was called in immediately, and seeing the nature of the attack sent for Dr Austin Flint, Jr Drs Isaac E Taylor and Wm T Lusk were called in consultation on Saturday, but the patient sank slowly, and died at 2 o'clock

Dr Flint was born in Petersham, Mass , on October 20, 1812, and was therefore in the seventy-fourth year of his age He came of a family that had made a name in medicine in Massachusetts since the early settlement of New England Thomas Flint, of Matlock, Derbyshire, England, the ancestor of Dr Austin Flint, settled in Concord in 1638 Edward Flint, the great grandfather of Dr Flint, was a physician of reputation in the Massachusetts Colony in the early part of the last century, and his grandfather, Dr Austin Flint, practised medicine in Leicester, Mass , until past the age of 90, dying in 1850 He laid aside his profession temporarily to enter the Revolutionary Army, but his services were soon needed as a surgeon Dr Flint's father, Joseph Henshaw Flint, was also a surgeon of reputation in Northampton and afterwards at Springfield Dr Flint pursued his academic studies at Amherst and Cambridge for three years, when he entered the medical department of Harvard College, and received the degree of M D , in 1833 The first three years of his professional life were passed in Northampton and Boston, when he removed to Buffalo, N Y , in 1836 He had already brought himself into prominence in the profession by his success as a practitioner and writer In 1844 he was appointed to the chair of Institutes and Practice of Medicine in the Rush Medical College of Chicago, though still retaining his residence in Buffalo This position he resigned at the end of a year In 1846, he founded the *Buffalo Medical Journal*, and for ten years edited it with marked ability and signal success His contributions to this periodical attracted attention on account of their unusual worth Among the physicians practising in Buffalo at this time were Dr James P White and Frank H Hamilton With these, in 1847, Dr Flint organized the Buffalo Medical College, which has also numbered among its professors, Drs John C Dalton and Sanford P Hunt In this institution Dr Flint was Professor of the Principles and Practice of Medicine and of Clinical Medicine until 1852, in which year he was called to the Chair of Theory and Practice of Medicine in the University of Louisville Here he remained until 1856, when he returned to Buffalo to take the Chair of Pathology and Clinical Medicine in the College which he had been instrumental in founding In 1858 he went to New Orleans to teach Clinical Medicine, where he was also visiting physician to the Charity Hospital He held these positions during the winters of 1858–1861, when he removed to New York to take the Chair of the Principles and Practice of Medicine and Clinical Medicine in Bellevue Hospital Medical College, and that of Pathology and Practical Medicine in the Long Island College Hospital to which he had been previously elected He was also appointed one of the physicians to Bellevue Hospital He relinquished the professorship in the Long Island College Hospital in 1868

Dr Flint went to New York distinguished as a practitioner, a teacher and an author Besides his other published writings he had presented two essays to the American Medical Association on "The Variations of Pitch in Percussion and Respiratory Sounds" (1852), and "The Clinical Study of the Heart Sounds in Health and Disease," (1859), for which he received the first prizes of the Association

When the National Medical Convention met in New York City on May 5, 1846, Dr Flint registered as a delegate from the Buffalo Medical Association, the other delegate being Dr Bryant Burwell This National Medical Convention, it will be remembered, was the initiatory step towards the formation of the American Medical Association Dr Flint was one of the seventy-four who voted against a resolution, offered on behalf of the New York State Medical Society, setting forth that there was no mode of accomplishing the object of the Convention, and suggesting that it adjourn *sine die* At this meeting he was appointed on a committee to report on a resolution, offered by the late Dr Isaac Hays, for a uniform and elevated standard of requirements for the degree of M D in all the medical schools of the United States The report of this committee, made in Philadelphia in 1847, at the second meeting of the Convention, is today a most interesting, applicable and valuable document

Soon after this meeting of the Convention Dr Flint, as already stated, helped to found the *Buffalo* Medical College, and seeing the difficulties under which medical schools labored in regard to subjects for practical anatomy, he introduced a resolution at the meeting in Philadelphia recommending that the medical profession of the different States unite in bringing their influence to bear on the legislatures to pass laws sanctioning and providing for dissection At this meeting also he was placed on the Committee on Medical Literature for the next year, Dr Oliver Wendell Holmes being Chairman of the Committee By this time he was already known favorably as a writer In 1849 he brought out an able article on the pathology of typhoid fever, giving an exact account of the intestinal lesions In an article on diabetes, published in his *Buffalo Medical Journal*, in July, 1848, he had confirmed the opinion expressed by Todd, of England, in the *Provincial Medical Journal*, three months before, as to the pathology of this affection "The presence of sugar in the blood and various secretions other than the urine render it inappropriate longer to rank diabetes among renal diseases" At the meeting of the *American Medical Association* in Cincinnati in 1850, for this name had been chosen at the Baltimore meeting of the National Convention, he was made Chairman of the Section of Practical Medicine, and the report on this subject shows how well he performed his work By this time several able papers had been given to the profession by him, notably two on serous effusion into the arachnoid cavity, which appeared in the *Buffalo Medical Journal*, in May, 1849, and April, 1850, and one on pleuro pneumonitis complicated with pericarditis, in the same periodical in February, 1850, in which he again pointed out the occasional connection of acute cerebral symptoms with lesions confined to the heart or pericardium, and the errors in diagnosis which may be made during life In November, 1849, he wrote a report on the epidemic of cholera in Buffalo in 1849 In the August, 1850, and succeeding numbers of his journal he gave a most elaborate analysis of fifty-two cases of typhoid fever, not only one of the most complete and valuable papers issued in the country during the year, but it remains to this day one of the most faithful expositions of the subject ever published in America Of this paper the Standing Committee of the Association on Medical Literature reported at the meeting in Charleston, in 1851 "We cannot, in justice to the labor and talent displayed speak of it merely as affording a rigid comprehensive analysis of the subject As an exposition of the clinical facts of the disease, as witnessed in this country, as an American work on fever, rich in material and admirable in execution, it is one of the best contributions ever published in the United States" His prize essay for 1852, on variations of pitch in percussion and respiratory sounds, has already been mentioned On the title page of this essay was the following quotation from Andry's work on Diseases of the Heart "Happy am I in my own estimation if I have thrown any light, in this Memoir, upon any clinical questions, and especially if I have stimulated the zeal of our young practitioners for the diagnostic studies which constitute, in my mind, one of the most beautiful parts of our art" In the same year he published his reports on Continued Fever, and in 1853 his clinical reports on Dysentery and on Chronic Pleurisy These papers, including the prize essay, were translated into French and published in Paris in 1854

Dr Flint's success as an author was not the result of chance An ever accumulating experience, added to patient work, with an analytical mind and a polished style, combined to make him one of the most agreeable of writers His writings may be held up as models of scientific style The conclusions drawn from facts were just and complete, the whole subject was stated fully, leaving nothing to be inferred He seemed to feel it his duty to his profession to contribute his quota to medical literature, as it is the duty of every physician who draws freely from the common stock At the meeting of the Association in Cleveland, Ohio, in 1883, Dr Flint was elected President, though he neither sought nor desired the office, and his masterly address in Washington will always remain an object of careful study by those who have the best interests of the Association at heart It was delivered just thirty-eight years after the first meeting of the National Medical Convention in New York, and opened with the words "The American Medical Association has reached an age when the thoughts of one whose retrospections extend to its birth, naturally revert to the natal period of its existence Of those who cooperated in the formation of the Association, not many now remain, and after a few more annual meetings all will have passed away" The objects of the Association, and the motives which led to its formation, are clearly and fully set forth It will be remembered that Dr Flint was made a member of the Committee on Medical Education at the first meeting of the National Convention, and in his address he ably discusses the practical question "What can the Association do to promote more and more the elevation of the standard of medical education? He shows that this can not be done by decrying the status of the profession "As a body," he says, "the members of our profession in this country are neither ignorant nor in any respect unworthy The profession is honorable and honored In no other country is the social status of its members higher"

At the meeting of the International Medical Congress in London, in 1881, Dr Flint read a paper on "The Analytical Study of Auscultation and Percussion with Reference to the Distinctive Characteristics of the Pulmonary Signs," a paper so suggestive and valuable that the brilliant and much lamented Mahomed suggested that a committee be appointed to report on a "Uniform Nomenclature of Auscultatory Sounds in the Diagnosis of Diseases of the Chest" Dr Flint was made Chairman of the Committee, and the report was made at the meeting of the International Congress in Copenhagen, in 1884 But though he probably did more good work in the department of diseases of the chest than any man of the century—certainly as much—he was in no sense a specialist He was not not only a born doctor, but an all round one His work in renal diseases was of the highest character, as will be seen from one article only, "The Elements of Prognosis in Bright's Disease," recently published in The Journal His published works and papers are so familiar that it is unnecessary to give the list in this place

---

At a meeting of the Faculty of the Bellevue Hospital Medical College held March 15, 1886, on motion it was resolved

That this Faculty keenly sympathizes with the wife son and family of our lamented *confrere*, Professor Austin Flint, in their irreparable loss of a tenderly devoted husband, father, and counsellor.

Yet that in their grief they will find consolation in that they can ever cherish the memory of his spotless life, his greatness and his goodness

That the son, grandson, and great grandson of eminent physicians and surgeons, entrusted by nature with medical skill and sagacity, so nobly fulfilled his mission

That his powers of thought and action were preserved in their fulness of vigor to the close of his intellectual and benevolent career

That his prayer was granted in being spared from lingering illness

That as he had mitigated the sufferings of others he himself was saved from suffering

That after a day and evening of arduous medical duties he retired to his painless couch of death—

"God's finger touched him and he slept"

Resolved, That this Faculty has been deprived in this dispensation of Providence of one of the most illustrious founders of this College, whose professors felt honored by having their names enrolled with his

One through whose instrumentality other medical colleges have been established in our country,

One whose pupils fill chairs in our Faculty, while others hold distinguished positions in similar institutions of medical instruction,

One whose self sacrificing and gratuitous services have been cheerfully rendered to the sufferers in Bellevue Hospital and other hospitals in our city and country for the last half century

Resolved, that our city and the world has lost in his death one whose noble presence and tender sympathies in the sick room cheered the heart and secured the confidence of the afflicted,

Whose remarkable record is justly the pride of any profession in any land,

Whose gifts and labors were recognized at home and abroad,

Who was honored with positions of distinction in America and Europe rarely won,

From whose eloquent lips thousands of students in many colleges have been taught the science of medicine, and by whose graphic pen tens of thousands have gained medical knowledge, and whose numerous and valued works translated into many tongues, will continue as fountains of instruction to future generations

Resolved, That while our heads bow in grief at his sudden death, our hearts rise in gratitude to God for his prolonged life of widely extended usefulness

Resolved, That a copy of these resolutions be engrossed and transmitted to his family, and that they be given for publication to the medical and secular journals of this city

We may fitly close this sketch by quoting the remarks of Dr Flint's long time friend, Dr John C Dalton, at the Commencement exercises of the Bellevue Hospital Medical College "I am sure there is but one thought in the minds of all who are here in this room this evening A familiar and venerated presence no longer meets your eyes from its accustomed place A voice to which you have listened, always with delight and profit, for so many years, is suddenly quiet on this returning anniversary And yet I doubt whether our departed friend and counsellor ever wielded over his colleagues or class such an overwhelming influence as he does at this moment

"He speaks to you to night not with the imperfect utterance of an occasional discourse or a momentary topic, but with the complete and unmistakable language of a lifetime He stands before you now in his entire character, ennobled by the record of his qualities and deeds, as the acknowledged representative of all that is best in the study, the teaching, and the practice of medical science and art It was the universal verdict, from which I have never heard a dissenting voice, that among all the eminent men of the profession in this wide country, his was the one name which would be inevitably selected as the first His single-minded devotion, untiring industry, and indomitable strength of purpose raised him long ago to the position which he held to the last day of his life And now, after conducting your studies through the session just closed, he has graduated before you, he has taken his final and highest degree, conferred by the Power that is Supreme over us all, and the parchment of his biography now bears the stamp of Emeritus

"For you, gentlemen of the medical class, I am sure that Dr Flint's teachings are far from being ended I can wish you nothing better than that you carry them with you throughout the future, and that you never cease to remember his instructions and to emulate his life"

MISCELLANEOUS

Medical Society of the State of Tennessee —The fifty third annual meeting of the Medical Society of the State of Tennessee will be held in Memphis, commencing Tuesday, April 6, 1886

Dr D D Saunders, of Memphis, is Chairman of the Committee of Arrangements

Members who cannot attend the meeting can retain their membership and receive a copy of the Transactions by forwarding $1 to the Treasurer

Members or delegates who desire to reach Memphis over the Louisville and Nashville system, should purchase regular tickets to Memphis and procure from the ticket agent, when these tickets are purchased, a certificate to this effect, which should be filled up by the Secretary of the meeting to show that the person named was in attendance and entitled to special rate, and upon presentation of the same to the agent at Memphis, he will sell return tickets at one-third fare The E T Va & Ga and the M & C will sell tickets to Memphis, at three cents per mile, issuing to each purchaser a certificate, on which, if properly signed by the Secretary of the Society, and presented to the ticket agent at Memphis, he will sell a return ticket at one cent per mile Tickets to be sold 3d, 4th, 5th and 6th of April, and return tickets to be sold 7th, 8th, 9th and 10th

C C Fite, *Secretary*

The American Surgical Association will meet in Washington, D C, on April 28, 29, 30, and May 1

The French Surgical Congress will be held in Paris on October 18 to 24 inclusive

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY FROM MARCH 13 1886 TO MARCH 19 1886

Capt Jno Van R Hoff, Asst Surgeon, ordered from Dept Cal to Dept Mo (S O 60, A G O, March 13, 1886)

Robertson, R L, 1st Lieut and Asst Surgeon, granted leave of absence for one month Fort Ringgold, Tex (S O 29, Dept Tex, March 8, 1886)

ATROPINE AND ESERINE IN OPHTHALMIC THERAPEUTICS

BY J W THOMPSON, M D,

OF ST PAUL, MINN

In a physiological sense atropine and eserine are synonymous with the terms mydriatic and myotic Each is a representative of the class to which it belongs Duboisine is a more powerful mydriatic than atropine, while pilocarpine is a greater irritant and a less powerful myotic than eserine A few cases that have come to my notice recently, forcibly illustrating the misuse, or I might say the abuse, of these valuable remedial agents furnish me material as well as occasion for inviting the attention of the profession to this seemingly threadbare subject The cases which I desire more especially to signalize at present were victims of the misapplied use of atropine Some of them had been rendered hopelessly blind by a single drop of a solution of the drug While it is perhaps impossible, in hundreds of cases, to show that any possible harm has resulted from the empirical use or administration of very many medicinal agents, it is quite different in the use of atropine as a mydriatic

In order to avoid almost or quite criminal mistakes in the application of this agent to diseases of the eye, it is absolutely indispensable that it be employed scientifically The same may be said of eserine, though mistakes with it occur less often only from the fact that a myotic in ophthalmic practice is less frequently demanded than a mydriatic It is by no means its inability to do harm when misapplied To illustrate my meaning better and to establish some definite data founded upon scientific investigation for the rational application of these agents which are so potent for good or evil, it becomes essential to look into certain diseased conditions of the eye which decidedly forbid or demand the application of one or the other of these drugs It is the absence of rational investigation that has led the way to much empiricism in the use especially of mydriatics The conditions that contra indicate their use are abundantly found in glaucoma I do not call to mind any disease in the whole category of human ills concerning which there have been advanced so many vague speculations and meaningless theories Its very name signifies ignorance in regard to the pathology of the disease it represents But I have neither time nor inclination to quarrel with its etymological signification Its long and intimate association with this fearful disease has clothed it with a meaning that perhaps entitles it to some respect and consideration

Before dropping a solution of atropine into the eye, examine carefully the intra ocular tension If this be above the normal, and the iris be free of inflammation, withhold the atropine until a further investigation is made Increased intra ocular tension unattended by other objective manifestations of disease can safely be taken as a key-note to glaucoma, in so far at least as the use of atropine is concerned For a better comprehension of the manner by which atropine energizes the glaucomatous process it becomes necessary to note the changes that take place within the eyeball at the very beginning of intra ocular tension This has been a fruitful subject of speculation So fruitful, indeed, has it been that to canvass the various theories that have from time to time been advocated concerning it would fill a volume of no mean dimensions It was formerly supposed to be the result of a hyper secretion Even von Grafe, whose brilliant acquisitions in the field of ophthalmology have earned for him an endless fame, entertained this erroneous view, and basing it upon the supposition that the iris furnished the superabundant secretion, did the iridectomy with the view of diminishing its secreting surface Thus did false reasoning stumble upon the remedy which is employed to day as the most successful means of combating this fearful disease Von Grafe was, however, one of the greatest pioneers in the field of ophthalmology He had not the advantages of the present He did not work with a light and strength borrowed from the past, hence the work he did was no measure of his capabilities

The increased intra ocular secretion is only one of the sequelæ of glaucoma, and the increased intra ocular tension is in the beginning only the physical sequence of the retention of a part or all of the normal intra ocular secretion In the posterior chamber the normal secretion is furnished by the ciliary bodies for the nourishment of the lens and its capsule After it has accomplished its purpose in the posterior chamber it passes through the pupillary opening into the anterior chamber and mingles with the fluid in this chamber which is secreted by the membrane of Decemet When its function here has been performed it is eliminated by the organs of elimination and taken up by the general circulation.

Thus the equilibrium is maintained between secretion and elimination. The eliminating apparatus is found chiefly in the anterior chamber at the point where the periphery of the cornea and the base of the iris seem to meet. This is composed of minute infiltration channels that are lined with endothelial cells, and communicate with the spaces of Fontana in the base of the iris. These in turn communicate with Schlem's canal, which passes around the eyeball in the sclerotic near the sclero corneal junction, and empties in the anterior ciliary veins. When, therefore, the organs of elimination become diseased and fail to do their duty, the first result is increased tension, which is the first symptom of glaucoma. All the other symptoms of this disease can be reasonably accounted for by taking the disease of elimination as the starting point. Hyper-secretion is only the pathological sequence of diseased and deficient elimination. When the intra ocular secretion is retained beyond the period of its utility it becomes disorganized, and furnishes a fruitful source of irritation and disease not only to the organs it was designed to nourish, but to all others with which it comes in contact. The consequent result of this is increased secretion. Hence the increased tension which had its origin in defective elimination is rapidly multiplied until it cuts off the circulation from the retina and optic nerve, which, together with the constant pressure maintained on these parts, produces atrophic changes which result sooner or later in the complete destruction of vision. From this it is evident that the retention of the worn out intra ocular secretion is responsible directly or indirectly for all the intra ocular changes that take place in glaucoma, and that this disease is properly speaking, a disease of elimination.

This hurried and imperfect explanation of the glaucomatous process clears the way to a better comprehension of the deleterious action of atropine and of the prophylactic influence of eserine in this disease. In other words, it enables one to discern more clearly how atropine may increase intra ocular tension and how eserine may diminish it. Atropine being a pupil dilator, forces the iris back into the angle of the anterior chamber, which is occupied by those minute channels which perform such an important part in the process of elimination. It causes the iris to act like a valve in closing them, thus destroying the equilibrium between elimination and secretion. It favors the accumulation of the latter and rapidly increases the intra ocular tension. I have, in one or two instances, known it to increase the tension so rapidly and violently as completely to destroy an eye in a few hours. It was so rapid and violent that it left no opportunity for operative interference, and left not a vestige of vision. Thus atropine not only accelerates the action of glaucoma, but may rapidly develop it in an eye verging upon this disease, or having only a slight predisposition to it. Eserine, being a pupil-contractor, pulls the iris away from the angle of the anterior chamber, and thus assists in freeing the obstructed organs of elimination. It is not claimed for eserine that it is capable of curing glaucoma when fully developed, for the iris under these circumstances may be widely dilated, pushed forward against the posterior surface of the cornea, and deprived perhaps of its contractile powers by the destructive action of the worn-out and retained secretion. So long, however, as the contractile power of the iris remains, eserine may prove invaluable by stimulating its contraction, and by this means breaking up the little bands of adhesion that may have formed in and about the drainage passages in the angle of the anterior chamber. The value of eserine is best demonstrated in an eye that is verging upon an attack of glaucoma. It may cure the predisposing tendency to this fearful disease. In other words, if timely employed it may tide it over altogether.

An eye is predisposed to glaucoma when the drainage channels are taxed to their utmost capacity to maintain under ordinary circumstances the equilibrium between secretion and elimination. When, however, by hypermetropia, injury, neuralgia, or sudden fright, the secretion is rapidly increased and thereby the drainage apparatus becomes further embarrassed by compression, the increased intra ocular tension must be the physical result which, if permitted to continue, will be rapidly followed by all the other symptoms of glaucoma. Eserine, if timely employed in such a case, may furnish complete relief by contracting the circular fibers of the iris and drawing the bulk of it away from the angle of the anterior chamber, and thus liberating the compressed drainage apparatus, while the use of atropine must produce a diametrically opposite result by dilating the iris and tucking it back, as it were, into the already narrowed angle of the anterior chamber, and thus further obstructing the drainage channels.

There have been many conflicting statements in regard to the action of atropine. Some have even asserted that it is powerless to diminish intra ocular tension, and in their eagerness to prove their assertions at all hazards, have made a shameful exhibition of ignorance by citing its action in glaucoma. This is only a repetition of the old story of "Hamlet with Hamlet left out." In a healthy eye with a full sized anterior chamber and a good drainage apparatus, atropine diminishes the volume of the healthy circulation. The physiological action of a drug may be as different from its therapeutical as disease is from health. It is the former action, however, that frequently furnishes rational data for its application in disease. In iritis there may also be increased intra ocular tension as the result of a swollen iris, and an increase of the intra ocular circulation. In tension arising from this cause atropine is indispensable. Increased tension in iritis is by no means constant, yet atropine is urgently demanded. It diminishes the tension in the same manner as it lowers the normal tension of a healthy eye. It relaxes the iris, diminishes the caliber of the vessels, and favors the absorption of the products of inflammation. It places the muscle in a state of physiological rest, which is the first indication to be met, if possible, in every inflamed organ or tissue. It is to the ophthalmic surgeon what splints and bandages are to the general surgeon. It is the great ocular sedative. It is as indispensable to the ophthalmic practitioner as opium and its preparations are to the general practitioner. The more useful is a remedial agent the greater is the tendency to its abuse. To avoid this evil a remedy should not be used empirically, but rather as a result of scientific investigation in so far as it is practicable.

Eserine in iritis would be almost as calamitous as atropine in glaucoma, by contracting the pupil, increasing the engorgement of the vessels and rendering the products of inflammation more profuse. Eserine, however, is often serviceable when there is a perforating ulcer in the periphery of the cornea, by contracting the iris and holding it away from the perforation, and thus, perhaps, preventing an anterior synechia. It has also been advantageously employed in retinitis pigmentosa. In this disease the periphery of the visual field is imperfect, and it is difficult for the patient to draw the line of demarcation between the perfect and the imperfect part of the field, and vision consequently becomes confused and indistinct. Eserine here contracts the pupil and cuts off the imperfect part of the visual field, which obtains for the patient a better definition of objects by permitting the use only of the central part of the field, in which there may be good sharpness of vision. Since this effect can readily be obtained by a mechanical device, I think its use for this purpose is very questionable. I have only time and space to observe that atropine is frequently indispensable in correcting errors of refraction by relaxing the spasm of accommodation. Since eserine and atropine are so potent for good or evil, it will be useful to have some well formulated ideas about their application. For this purpose I will summarize as briefly as possible, first, the various effects of atropine on the healthy eye. It lessens intra ocular tension in an eye that is healthy and normally constructed. By normal construction I mean an eye that is emmetropic and has a full sized anterior chamber.

In such an eye the atropine lessens intra ocular tension by diminishing the calibre and contents of internal vessels and checking the secretion of the ciliary bodies. It lessens the tension in iritis by contracting the radial fibres of the iris, which in turn contract the over distended and engorged blood vessels, thus diminishing the bulk of the iris and the ciliary bodies. It checks the inflammatory exudation and favors its absorption. It also diminishes the cell proliferation and the transmigration of white corpuscles, and by contracting the iris it breaks up synechiæ that may have been formed, and reestablishes a free communication between the chambers, allowing the secretion to reach the organs of elimination.

Atropine increases intra ocular tension when there is a shallow anterior chamber by dilating the iris and tucking it back into the angle of the anterior chamber, and compressing the channels of elimination. In serous iritis its action is feeble, changeable and unreliable. Eserine diminishes intra-ocular tension when the anterior chamber is shallow, the iris sluggish and partially dilated, with its anterior surface resting perhaps against the posterior surface of the cornea, by contracting the circular fibres of the iris and drawing it away from the angle of the anterior chamber and freeing the eliminating channels, and thus reestablishing the equilibrium between secretion and elimination. In serous iritis the anterior chamber is deepened by the iris being somewhat dilated and pressed backwards against the lens capsule. Here eserine is rather uncertain, yet it may be safely employed with the view of breaking up any little adhesions that may have formed about the drainage channels. Again, eserine increases intra ocular tension temporarily in a healthy eye by increasing the quantity of the circulation in the iris and the ciliary bodies, which in turn increases their secretion. For a similar reason it increases the tension in iritis, and therefore augments the products of inflammation and favors adhesions of the iris to the cornea or the lens capsule. Therefore, I reiterate, atropine in glaucoma hastens the destruction of the eye, and in an eye verging upon glaucoma may rapidly develop the disease in the most violent form. Eserine may prevent the occurrence of glaucoma when an eye is predisposed to the disease and mitigate the symptoms of a fully developed case, and as it were postpone the destruction of the organ till an iridectomy can be done for its relief. In iritis atropine is absolutely indispensable and eserine may destroy the organ in a very short space of time. Hence, it is as important to know when to withhold these remedies as it is to know when to employ them. I am free to admit that the indications for their use are sometimes surrounded with perplexities and doubts.

> "Our doubts are traitors,
> And make us lose the good we oft might win
> By fearing to attempt."

Pliny says "Never do anything concerning the rectitude of which you have a doubt." The attempt to decide certain obscure cases extemporaneously and hastily has resulted many times in the loss of the patient's vision and the physician's reputation. To rid this important subject as much as possible of the doubts and perplexities that occasionally surround it, I will classify certain prominent objective symptoms which should always be carefully reviewed before dropping into an eye either a solution of atropine or eserine.

In glaucoma the circumcorneal injection is well pronounced and has a decided venous hue. The eye presents a dusky, staring appearance. The entire surface of the cornea is steamy and looks much like ground glass. The anterior chamber is very shallow, the aqueous humor, from the diminished calibre of the chambers, appears scanty. The pupil is widely dilated and ovoid in form. The iris appears thin, dull, stationary, its fibres obliterated and its surface bulged forwards till it nearly or quite touches the posterior surface of the cornea. Observing the same order of symptoms in serous iritis, the circumcorneal injection is rather indistinct and not so well marked as in glaucoma, and the tint is more delicate, the haziness of the cornea is not so uniform, and the lower segment of it on its inner surface is irregularly occupied with small white dots more or less numerous in proportion to the severity of the attack. The anterior chamber is deep and large mostly at the expense of the posterior chamber. The aqueous humor

Thus the equilibrium is maintained between secretion and elimination. The eliminating apparatus is found chiefly in the anterior chamber at the point where the periphery of the cornea and the base of the iris seem to meet. This is composed of minute infiltration channels that are lined with endothelial cells, and communicate with the spaces of Fontana in the base of the iris. These in turn communicate with Schlem's canal, which passes around the eyeball in the sclerotic near the sclero corneal junction, and empties in the anterior ciliary veins. When, therefore, the organs of elimination become diseased and fail to do their duty, the first result is increased tension, which is the first symptom of glaucoma. All the other symptoms of this disease can be reasonably accounted for by taking the disease of elimination as the starting point. Hyper secretion is only the pathological sequence of diseased and deficient elimination. When the intra ocular secretion is retained beyond the period of its utility it becomes disorganized, and furnishes a fruitful source of irritation and disease not only to the organs it was designed to nourish, but to all others with which it comes in contact. The consequent result of this is increased secretion. Hence the increased tension which had its origin in defective elimination is rapidly multiplied until it cuts off the circulation from the retina and optic nerve, which, together with the constant pressure maintained on these parts, produces atrophic changes which result sooner or later in the complete destruction of vision. From this it is evident that the retention of the worn out intra ocular secretion is responsible directly or indirectly for all the intra ocular changes that take place in glaucoma, and that this disease is properly speaking, a disease of elimination.

This hurried and imperfect explanation of the glaucomatous process clears the way to a better comprehension of the deleterious action of atropine and of the prophylactic influence of eserine in this disease. In other words, it enables one to discern more clearly how atropine may increase intra ocular tension and how eserine may diminish it. Atropine being a pupil dilator, forces the iris back into the angle of the anterior chamber, which is occupied by those minute channels which perform such an important part in the process of elimination. It causes the iris to act like a valve in closing them, thus destroying the equilibrium between elimination and secretion. It favors the accumulation of the latter and rapidly increases the intra ocular tension. I have, in one or two instances, known it to increase the tension so rapidly and violently as completely to destroy an eye in a few hours. It was so rapid and violent that it left no opportunity for operative interference, and left not a vestige of vision. Thus atropine not only accelerates the action of glaucoma, but may rapidly develop it in an eye verging upon this disease, or having only a slight predisposition to it. Eserine, being a pupil contractor, pulls the iris away from the angle of the anterior chamber, and thus assists in freeing the obstructed organs of elimination. It is not claimed for eserine that it is capable of curing glaucoma when fully developed, for the iris under these circumstances may be widely dilated, pushed forward against the posterior surface of the cornea, and deprived perhaps of its contractile powers by the destructive action of the worn out and retained secretion. So long, however, as the contractile power of the iris remains, eserine may prove invaluable by stimulating its contraction, and by this means breaking up the little bands of adhesion that may have formed in and about the drainage passages in the angle of the anterior chamber. The value of eserine is best demonstrated in an eye that is verging upon an attack of glaucoma. It may cure the predisposing tendency to this fearful disease. In other words, if timely employed it may tide it over altogether.

An eye is predisposed to glaucoma when the drainage channels are taxed to their utmost capacity to maintain under ordinary circumstances the equilibrium between secretion and elimination. When, however, by hypermetropia, injury, neuralgia, or sudden fright, the secretion is rapidly increased and thereby the drainage apparatus becomes further embarrassed by compression, the increased intra ocular tension must be the physical result which, if permitted to continue, will be rapidly followed by all the other symptoms of glaucoma. Eserine, if timely employed in such a case, may furnish complete relief by contracting the circular fibers of the iris and drawing the bulk of it away from the angle of the anterior chamber, and thus liberating the compressed drainage apparatus, while the use of atropine must produce a diametrically opposite result by dilating the iris and tucking it back, as it were, into the already narrowed angle of the anterior chamber, and thus further obstructing the drainage channels.

There have been many conflicting statements in regard to the action of atropine. Atropine increases intra-ocular tension when there is a shallow anterior chamber by dilating the iris and tucking it back into the angle of the anterior chamber, and compressing the channels of elimination In serous iritis its action is feeble, changeable and unreliable Eserine diminishes intra-ocular tension when the anterior chamber is shallow, the iris sluggish and partially dilated, with its anterior surface resting perhaps against the posterior surface of the cornea, by contracting the circular fibres of the iris and drawing it away from the angle of the anterior chamber and freeing the eliminating channels, and thus reestablishing the equilibrium between secretion and elimination In serous iritis the anterior chamber is deepened by the iris being somewhat dilated and pressed backwards against the lens capsule Here eserine is rather uncertain, yet it may be safely employed with the view of breaking up any little adhesions that may have formed about the drainage channels Again, eserine increases intra ocular tension temporarily in a healthy eye by increasing the quantity of the circulation in the iris and the ciliary bodies, which in turn increases their secretion For a similar reason it increases the tension in iritis, and therefore augments the products of inflammation and favors adhesions of the iris to the cornea or the lens capsule Therefore, I reiterate, atropine in glaucoma hastens the destruction of the eye, and in an eye verging upon glaucoma may rapidly develop the disease in the most violent form Eserine may prevent the occurrence of glaucoma when an eye is predisposed to the disease and mitigate the symptoms of a fully developed case, and as it were postpone the destruction of the organ till an iridectomy can be done for its relief In iritis atropine is absolutely indispensable and eserine may destroy the organ in a very short space of time Hence, it is as important to know when to withhold these remedies as it is to know when to employ them I am free to admit that the indications for their use are sometimes surrounded with perplexities and doubts

> "Our doubts are traitors,
> And make us lose the good we oft might win
> By fearing to attempt"

Pliny says "Never do anything concerning the rectitude of which you have a doubt" The attempt to decide certain obscure cases extemporaneously and hastily has resulted many times in the loss of the patient's vision and the physician's reputation To rid this important subject as much as possible of the doubts and perplexities that occasionally surround it, I will classify certain prominent objective symptoms which should always be carefully reviewed before dropping into an eye either a solution of atropine or eserine

In glaucoma the circumcorneal injection is well pronounced and has a decided venous hue The eye presents a dusky, staring appearance The entire surface of the cornea is steamy and looks much like ground glass The anterior chamber is very shallow, the aqueous humor, from the diminished calibre of the chambers, appears scanty The pupil is widely dilated and ovoid in form The iris appears thin, dull, stationary, its fibres obliterated and its surface bulged forwards till it nearly or quite touches the posterior surface of the cornea Observing the same order of symptoms in serous iritis, the circumcorneal injection is rather indistinct and not so well marked as in glaucoma, and the tint is more delicate, the haziness of the cornea is not so uniform, and the lower segment of it on its inner surface is irregularly occupied with small white dots more or less numerous in proportion to the severity of the attack The anterior chamber is deep and large mostly at the expense of the posterior chamber The aqueous humor is abundant and more or less turbid The iris presents a sullied, dirty appearance, though not so lustreless as in glaucoma Its fibrillar structure is better preserved The pupil is dilated and round, while in glaucoma it is ovoid in form

In iritis the circumcorneal injection presents a moderately well marked, red color, due to arterial as well as venous injection The cornea is unaffected The anterior chamber is shallower than normal, caused by the thickened condition of the iris The aqueous humor is more or less turbid in consequence of the effused products of inflammation The pupil is somewhat contracted, irregular, and in severe cases adherent posteriorly or anteriorly The iris is thick and swollen, discolored and somewhat nodular

Such are the prominent objective symptoms that may assist in doubtful cases to differentiate between glaucoma, iritis and serous iritis Let the watchword be "atropine in iritis and eserine in glaucoma"

THE MECHANISM OF INDIRECT FRACTURES OF THE SKULL

BY CHARLES W DULLES, M D,

SURGEON TO THE OUTPATIENT DEPARTMENT OF THE HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA AND OF THE PRESBYTERIAN HOSPITAL IN PHILADELPHIA

(Continued from page 342)

ANATOMICAL PECULIARITIES OF THE SKULL

Having now briefly considered the elastic properties of the skull, let us next study its anatomical peculiarities, which, as I have already pointed out, may be expected to modify the results which might be expected if the shape of the skull were regular and its thickness uniform These peculiarities must be given due consideration if we would avoid the error of applying too rigorously the bursting theory, at the same time they must not be over-estimated This was the error of Félizet, who was right in attaching great importance to the architectonic conditions of the skull, but who was mistaken in supposing that his buttresses and centre of resistance would stand firm against all or most fractures So Aran, before him, was right in supposing that fractures starting in one fossa of the skull would often be limited to that fossa, but he erred in supposing this could be stated as a general law Both of these theories depended upon what we may call the accidents of fractures of the skull, the essential, I believe—and the future may show that this view may be applied too rigorously—is to be found in the elastic properties of the skull, as revealed not only by the experiments of von Bruns and of his German followers, but also by those of Aran and of Félizet themselves, and by the investigations of others before their time, to whom allusion has already been made in the historical sketch at the beginning of this paper The thinnest portions of the various bones of the skull are as follows

In the frontal bone The walls of the frontal sinuses, the orbital plates, the temporal portions, and sometimes on both sides of the crest for the attachment of the falx cerebri

In the ethmoid bone The horizontal plate (The other parts of the bone may be regarded as outside of the true cranial case)

In the sphenoid bone The orbital portion of the greater wings, and the walls of the sphenoidal sinuses The basilar portion of this bone has a deceptive appearance of strength, on account of its thickness, but on section it will be seen to be of such open cancellated structure that it is not surprising to find that it is very often fractured

In the parietal bones The lower border, just above the parieto squamosal suture, and both of the inferior angles

In the occipital bone The floor of the cerebellar fossæ, and to a less extent the floor of the posterior cerebral fossæ

In the temporal bones I take these bones last because they present some extremely interesting anatomical peculiarities, the importance of which I have not found dwelt upon as I think it ought to be The thinness of the squamous plates is too familiar to need more than mention But the temporal bone is also often very thin over the cotyloid depression for the head of the inferior maxilla The mastoid portion is also sometimes occupied by such large open spaces as materially to weaken its walls The petrous portion does not, on section, present everywhere that solid and rocky appearance to which it owes its name, and which it only partly deserves The roof of the external auditory meatus is sometimes very thin, in a line parallel to and anterior to the superior ridge of the bone The floor of this canal is also comparatively thin The plate of vitreous which covers the anterior inclined plane of the bone is often a mere shell over the promontory above the inferior semicircular canal, and further back, in front of the groove for the superior petrosal sinus, it overlies a mass of honeycombed cancellated tissue which communicates with the large cells of the mastoid process These facts explain the many fractures which are found to run parallel to the crest of this bone, and which have often been wondered at In like manner the curious course which a fracture sometimes takes at right angles to the main axis of the petrous bone may be understood when we study the channels and excavations belonging to the middle and internal ear, the internal auditory meatus, the carotid canal, the groove for the inferior petrosal sinus, and the jugular foramen

These are some of the weak points of the bones of the skull Others might be mentioned, as for example, the antero lateral rim of the foramen magnum, which, in some cases, is very porous, and far from so strong as its thickness would indicate It will be noticed that all of these thin parts of the skull lie in or near the base, and clinical observation shows that they are very frequently the seat of fracture There are a few other anatomical peculiarities of the skull to which I would like to call your attention before I leave a part of our subject which might well occupy much more time than we can spare it First, in regard to the posterior clinoid processes It was long a matter entirely unexplained that violence done to the skull was followed by no fracture, except one breaking off the posterior clinoid processes of the sphenoid bone. But the explanation is easy enough if we accept the "bursting theory," and recognize the fact that the tentorium cerebelli is attached in front to these processes, and that when the long diameter of the skull is increased the tense tentorium holds back with an unyielding strain and tears these processes from their attachments to the rest of the bone. In this we have both a full explanation of the mechanism of these fractures and a beautiful confirmation of the "bursting theory" of indirect fractures of the skull.

Again, I may call attention to the peculiar conditions of the basi sphenoid and petrous bones. These bones are never, I believe, united by bony union or close fitting dentations, like the other bones of the skull. Their adjacent surfaces are simply applied against each other and united by a membranous or ligamentous band. The plane in which these bones articulate is such that the basi sphenoid is placed like a wedge between the apices of the two petrous bones. As a consequence, any force, like a blow on the vertex driving the cranium down upon the spinal column, or a fall upon the buttocks or feet, driving the spinal column up against the cranium will have the effect of forcing the wedge shaped basi sphenoid upward and forward between the two rigid petrous bones, with the frequent result of knocking off one or both of the apices of the latter. This form of fracture is another which has excited much surprise and some fanciful explanations, but, in the light of what has just been stated, it seems to me to be quite comprehensible.

Finally, I have been struck by the fact that certain peculiar fractures of the base of the skull seem to have been due to support of a segment of the occipital bone furnished by the inclination upward and outward of the articular surfaces of the atlas, which embrace the condyles of the occipital bone and restrain it from rupture to such an extent that a fissure will pass on both sides of the protected region rather than through it. This form of fracture is illustrated by a beautiful specimen taken from the Mutter Museum of this College.

ARCHITECTONIC PECULIARITIES OF THE SKULL.

I cannot now do more than allude to the general oval shape of the skull, its various curves, arches, and buttresses, the comparatively even shape and homogeneous character of the vault, and the irregular shape and varying thickness and thinness of the base, with its prominences and depressions, its channels and its so called sinuses. These are too complex to be detailed here, and too familiar to all to make this necessary. But I would call your attention to what Félizet has laid so much stress upon, the reinforcement of certain regions, as at the junction of the greater wings of the sphenoid bone with the frontal and temporal bones, and of the petrous portion of the temporal bones with the parietals, at the ridge for the attachment of the longitudinal and lateral sinuses within the skull and at those for the attachment of muscles at the back of the head, which vary in importance in different individuals. In addition, we may well bear in mind the comparative roundness of the vault and flatness of the base, and the wedge like insertion of the lower borders of the parietal bones between the bevelled upper edges of the squamous bones, and the projection of the ends of the petrous bones against the basi sphenoid, of which I have already spoken in detail. For most of the points one may consult the works on general and special anatomy, or, better still, the skull itself. They all must be considered in studying variations from the result to be expected from the application of any given theory in regard to the mechanism of fractures of the skull, although, as I have said, they need not be expected to controvert any law of general applicability.

INFLUENCE OF THE SOFT PARTS AND CONTENTS OF THE SKULL.

This is another portion of the study of fractures of the skull to which more time ought to be devoted than we can spare now. In a general way, it may be said that the external and internal coverings of the skull—the dura mater and the pericranium, with the muscles, fasciæ, and skin—tend not only to deaden vibrations to such an extent that it is hard to know how to understand many expressions of those who have accepted what is known as the "vibration theory," but also to limit to a moderate extent the changes in shape which the skull may undergo, according to the "bursting theory." The action of the muscles must also be considered of importance, as exemplified in such involuntary and spasmodic contractions as prove sufficient of themselves to break other bones, and which may have more effect here than has yet been suspected. Let us imagine, for example, what might be the effect of a spasmodic contraction of the erector mass at the back of the head when a sudden blow comes upon the anterior part of the vertex, tending to flex the head. I wish it were possible to go further into this inviting field of investigation.

As to the contents of the skull, Fabricius ab Aquapendente attributed fractures by counterstroke to the effort of the air, which he supposed the skull to contain, to escape from its cavity. We know better than this, but it does not seem needless to call attention to the fact that the skull is filled with a much more incompressible material than air. In fact, the brain and its membranes, with the surrounding fluid, completely fill the skull with the most incompressible materials of which we have any knowledge. Under the influence of a blow, this material tends to increase the disruptive force, according to the well known laws of hydrostatics. As a full cask may be burst by a blow, so there can be no doubt the skull may likewise be burst. The statements often made, which affirm or imply that the skull and its contents can be compared to a water bed, are utterly erroneous. The fluid contained in the cranium, in a state of health, is far too little to justify any such comparison. Besides which, it is contained in a firm, unyielding case, while it is indispensable to a water bed that its walls shall be soft and yielding. It has also been intimated—and so able a man as Mr. Hilton thought he had demonstrated—that displacement of the cerebro-spinal fluid could be regarded as a protective against is abundant and more or less turbid The iris presents a sullied, dirty appearance, though not so lustreless as in glaucoma Its fibrillar structure is better preserved The pupil is dilated and round, while in glaucoma it is ovoid in form

In iritis the circumcorneal injection presents a moderately well marked, red color, due to arterial as well as venous injection The cornea is unaffected The anterior chamber is shallower than normal, caused by the thickened condition of the iris The aqueous humor is more or less turbid in consequence of the effused products of inflammation The pupil is somewhat contracted, irregular, and in severe cases adherent posteriorly or anteriorly The iris is thick and swollen, discolored and somewhat nodular

Such are the prominent objective symptoms that may assist in doubtful cases to differentiate between glaucoma, iritis and serous iritis Let the watchword be "atropine in iritis and eserine in glaucoma"

THE MECHANISM OF INDIRECT FRACTURES OF THE SKULL

BY CHARLES W DULLES, M D,

SURGEON TO THE OUTPATIENT DEPARTMENT OF THE HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA AND OF THE PRESBYTERIAN HOSPITAL IN PHILADELPHIA

(*Continued from page 342*)

ANATOMICAL PECULIARITIES OF THE SKULL

Having now briefly considered the elastic properties of the skull, let us next study its anatomical peculiarities, which, as I have already pointed out, may be expected to modify the results which might be expected if the shape of the skull were regular and its thickness uniform These peculiarities must be given due consideration if we would avoid the error of applying too rigorously the bursting theory, at the same time they must not be over estimated This was the error of Félizet, who was right in attaching great importance to the architectonic conditions of the skull, but who was mistaken in supposing that his buttresses and centre of resistance would stand firm against all or most fractures So Aran, before him, was right in supposing that fractures starting in one fossa of the skull would often be limited to that fossa, but he erred in supposing this could be stated as a general law Both of these theories depended upon what we may call the accidents of fractures of the skull, the essential, I believe—and the future may show that this view may be applied too rigorously—is to be found in the elastic properties of the skull, as revealed not only by the experiments of von Bruns and of his German followers, but also by those of Aran and of Félizet themselves, and by the investigations of others before their time, to whom allusion has already been made in the historical sketch at the beginning of this paper The thinnest portions of the various bones of the skull are as follows

In the frontal bone The walls of the frontal sinuses, the orbital plates, the temporal portions, and sometimes on both sides of the crest for the attachment of the falx cerebri

In the ethmoid bone The horizontal plate (The other parts of the bone may be regarded as outside of the true cranial case)

In the sphenoid bone The orbital portion of the greater wings, and the walls of the sphenoidal sinuses The basilar portion of this bone has a deceptive appearance of strength, on account of its thickness, but on section it will be seen to be of such open cancellated structure that it is not surprising to find that it is very often fractured

In the parietal bones The lower border, just above the parieto squamosal suture, and both of the inferior angles

In the occipital bone The floor of the cerebellar fossæ, and to a less extent the floor of the posterior cerebral fossæ

In the temporal bones I take these bones last because they present some extremely interesting anatomical peculiarities, the importance of which I have not found dwelt upon as I think it ought to be The thinness of the squamous plates is too familiar to need more than mention But the temporal bone is also often very thin over the cotyloid depression for the head of the inferior maxilla The mastoid portion is also sometimes occupied by such large open spaces as materially to weaken its walls The petrous portion does not, on section, present everywhere that solid and rocky appearance to which it owes its name, and which it only partly deserves The roof of the external auditory meatus is sometimes very thin, in a line parallel to and anterior to the superior ridge of the bone The floor of this canal is also comparatively thin The plate of vitreous which covers the anterior inclined plane of the bone is often a mere shell over the promontory above the inferior semicircular canal, and further back, in front of the groove for the superior petrosal sinus, it overlies a mass of honeycombed cancellated tissue which communicates with the large cells of the mastoid process These facts explain the many fractures which are found to run parallel to the crest of this bone, and which have often been wondered at In like manner the curious course which a fracture sometimes takes at right angles to the main axis of the petrous bone may be understood when we study the channels and excavations belonging to the middle and internal ear, the internal auditory meatus, the carotid canal, the groove for the inferior petrosal sinus, and the jugular foramen

These are some of the weak points of the bones of the skull Others might be mentioned, as for example, the antero lateral rim of the foramen magnum, which, in some cases, is very porous, and far from so strong as its thickness would indicate It will be noticed that all of these thin parts of the skull lie in or near the base, and clinical observation shows that they are very frequently the seat of fracture There are a few other anatomical peculiarities of the skull to which I would like to call your attention before I leave a part of our subject which might well occupy much more time than we can spare it First, in regard to the posterior clinoid processes It was long a matter entirely unexplained that violence done to the skull was followed by no fracture, except one breaking off the posterior clinoid processes of the sphenoid bone But the explanation is easy enough if we accept the "bursting theory," and recognize the fact that the tentorium cerebelli is attached in front to these processes, and that when the long diameter of the skull is increased the tense tentorium holds back with an unyielding strain and tears these processes from their attachments to the rest of the bone In this we have both a full explanation of the mechanism of these fractures and a beautiful confirmation of the "bursting theory" of indirect fractures of the skull

Again, I may call attention to the peculiar conditions of the basi-sphenoid and petrous bones These bones are never, I believe, united by bony union or close fitting dentations, like the other bones of the skull Their adjacent surfaces are simply applied against each other and united by a membranous or ligamentous band The plane in which these bones articulate is such that the basi sphenoid is placed like a wedge between the apices of the two petrous bones As a consequence, any force, like a blow on the vertex driving the cranium down upon the spinal column, or a fall upon the buttocks or feet, driving the spinal column up against the cranium will have the effect of forcing the wedge shaped basi sphenoid upward and forward between the two rigid petrous bones, with the frequent result of knocking off one or both of the apices of the latter This form of fracture is another which has excited much surprise and some fanciful explanations, but, in the light of what has just been stated, it seems to me to be quite comprehensible

Finally, I have been struck by the fact that certain peculiar fractures of the base of the skull seem to have been due to support of a segment of the occipital bone furnished by the inclination upward and outward of the articular surfaces of the atlas, which embrace the condyles of the occipital bone and restrain it from rupture to such an extent that a fissure will pass on both sides of the protected region rather than through it This form of fracture is illustrated by a beautiful specimen taken from the Mutter Museum of this College

ARCHITECTONIC PECULIARITIES OF THE SKULL

I cannot now do more than allude to the general oval shape of the skull, its various curves, arches, and buttresses, the comparatively even shape and homogeneous character of the vault, and the irregular shape and varying thickness and thinness of the base, with its prominences and depressions, its channels and its so called sinuses These are too complex to be detailed here, and too familiar to all to make this necessary But I would call your attention to what Felizet has laid so much stress upon, the reinforcement of certain regions, as at the junction of the greater wings of the sphenoid bone with the frontal and temporal bones, and of the petrous portion of the temporal bones with the parietals, at the ridge for the attachment of the longitudinal and lateral sinuses within the skull and at those for the attachment of muscles at the back of the head, which vary in importance in different individuals In addition, we may well bear in mind the comparative roundness of the vault and flatness of the base, and the wedge-like insertion of the lower borders of the parietal bones between the bevelled upper edges of the squamous bones, and the projection of the ends of the petrous bones against the basi sphenoid, of which I have already spoken in detail For most of the points one may consult the works on general and special anatomy, or, better still, the skull itself They all must be considered in studying variations from the result to be expected from the application of any given theory in regard to the mechanism of fractures of the skull, although, as I have said, they need not be expected to controvert any law of general applicability

INFLUENCE OF THE SOFT PARTS AND CONTENTS OF THE SKULL

This is another portion of the study of fractures of the skull to which more time ought to be devoted than we can spare now In a general way, it may be said that the external and internal coverings of the skull—the dura mater and the pericranium, with the muscles, fasciæ, and skin—tend not only to deaden vibrations to such an extent that it is hard to know how to understand many expressions of those who have accepted what is known as the "vibration theory," but also to limit to a moderate extent the changes in shape which the skull may undergo, according to the "bursting theory" The action of the muscles must also be considered of importance, as exemplified in such involuntary and spasmodic contractions as prove sufficient of themselves to break other bones, and which may have more effect here than has yet been suspected Let us imagine, for example, what might be the effect of a spasmodic contraction of the erector mass at the back of the head when a sudden blow comes upon the anterior part of the vertex, tending to flex the head I wish it were possible to go further into this inviting field of investigation

As to the contents of the skull, Fabricius ab Aquapendente attributed fractures by counterstroke to the effort of the air, which he supposed the skull to contain, to escape from its cavity We know better than this, but it does not seem needless to call attention to the fact that the skull is filled with a much more incompressible material than air In fact, the brain and its membranes, with the surrounding fluid, completely fill the skull with the most incompressible materials of which we have any knowledge Under the influence of a blow, this material tends to increase the disruptive force, according to the well-known laws of hydrostatics As a full cask may be burst by a blow, so there can be no doubt the skull may likewise be burst The statements often made, which affirm or imply that the skull and its contents can be compared to a water bed, are utterly erroneous The fluid contained in the cranium, in a state of health, is far too little to justify any such comparison Besides which, it is contained in a firm, unyielding case, while it is indispensable to a water bed that its walls shall be soft and yielding It has also been intimated —and so able a man as Mr Hilton thought he had demonstrated— that displacement of the cerebro-spinal fluid could be regarded as a protective against injury when the skull was struck Mr Hilton's experiment was not free from an important source of error, and one who studies carefully the anatomical peculiarities of the cerebro spinal axis must see, I think, that there is only one way for compensatory diminution in the contents of the skull to take place, namely, by displacement of its contained blood through its natural channels This displacement can and does take place when time is afforded for the process, as in the case of a growing tumor, but the rapidity with which a blow tends to diminish the capacity of the cranium far outstrips the speed with which the blood can escape, so that, as a matter of fact, the skull and its contents may be regarded as the very opposite of a water-bed, and more like a cask filled with fluid which may burst under a sudden increase of the pressure upon the inside of its walls This fact is established not only by a correct knowledge of the physical conditions of the cerebro spinal axis, but also by experiments and observations which I cannot stop to mention now

STUDY OF CASES

A great difficulty confronts at the outset one who tries to discover in how far the study of actual fractures of the skull will bear out any theory in regard to their mechanism which seems plausible The difficulty depends upon the difference between the known factors in an experiment and the unknown factors in an accident It is often impossible in the case of a fracture of the skull, to ascertain exactly the amount and direction of the force, the point to which it was applied, and the conditions of resistance or evasion of the whole cranial box The consideration should lead to a modest and reserved fitting of what seemed to be facts to any theory Nevertheless, nothing can be learned by standing still, and we may, if not over confident, make some advance in knowledge by testing a theory by an observation of what actually takes place With this object in view I have examined the published accounts of a very large number of cases of fracture of the skull, and I have collected more than a hundred (119) in which the details seem to me to be sufficient to warrant an approximative estimate as to the conditions under which the fracture occurred, and as to the results produced

Class A^1 *Fractures caused by blows on the frontal region* Of this class I have only two cases One caused by a kick from a horse above the right eyebrow, causing a direct fracture here, and an indirect meridional and oblique fracture of the parietal bone of the same side The other case presents a fracture caused by a blow with the handle of a pitchfork, high up on the frontal region The fracture is in the base, is meridional, and passes from the right orbital plate through the sphenoid bone and the basilar process of the occipital, leaping across the foramen magnum, from the back edge of which start two converging fissures which meet in the cerebellar fossa on the left side, and above the groove for the lateral sinus

Class A *Fractures caused by falls upon the frontal region* Of these I have thirteen cases Twelve present meridional fissures, five of them being directly longitudinal, three of these passing directly through the whole basi sphenoid bone Seven are oblique, two of them bifurcated, and one passing through the whole basi sphenoid bone, one passes from the point of impact to the lower part of the ridge for the straight sinus, after having passed across the middle of the petrous bone and encircled the foramen magnum One shows a ring fracture, in addition to a meridional fracture from the frontal bone to the junction of the petrous with the basi sphenoid One is directly opposite to the point struck, is extensive and bifurcated

Class B^1 *Fractures caused by blows on the occipital region* Of these I have only two cases One was caused by a spent ball striking the occiput to the left of the middle line, and shows an independent meridional fracture passing alongside of the internal ridge to near the foramen magnum, then crossing the petrous bone, dividing it transversely to its principal axis, and ending in the foramen spinosum The other case is a specimen from one of Perrin's experiments, in which the skull was thrown on a stone pavement covered with a layer of india rubber There is a separation of the coronal suture, and a prolongation of this as a bifurcated fissure in the right squamous bone This specimen shows a division at right angles to the meridian, which may be due to an unusually weak union in the coronal suture, or to some peculiarity of the experiment I have included this specimen among my drawings, because it is diametrically opposed to the bursting theory But I think an experiment which involves throwing a skull detached from the body cannot be considered very reliable in comparison with those in which the skull is fixed

Class B *Fractures caused by falls, striking upon the occipital region* Of these I have twenty one cases All show meridional fractures Two of these pass directly through the crest for the lodgment of the straight sinus to the foramen magnum One passes to the foramen magnum near this crest Two pass through the whole of one side of the occipital bone, and one splits off a piece of the parietal, and separates the lambdoid suture in part One divides the frontal bone into halves Six pass round the foramen magnum on one side, three dividing the petrous bone longitudinally and one transversely One shows a longitudinal fracture passing across the foramen magnum and dividing the basi sphenoid bone, as well as a partial ring fracture In two the fracture passes meridionally round the side of the head One shows an independent fissure on each side, in the parietal bones

Class B^3 *Fractures due to blows on both the forehead and occiput* One such case I have found recorded by Herpin, in which there was a succession of bumps on each of these parts The resulting fracture is a long fissure, passing longitudinally from the internal occipital protuberance to the foramen cæcum, passing round the foramen magnum, very close to it, and dividing the whole of the basi sphenoid, a beautiful meridional fissure

Class C^1 *Fractures caused by compression in a longitudinal direction accidental* Hewitt records two cases of this sort In the first, a man fell on the back of his head, and a piece of timber fell on his forehead The fissure is independent, and partly meridional It divides longitudinally the middle of the horizontal plate of the ethmoid bone and the middle of the body of the sphenoid bone, passing then to the right through the greater wing of this bone, and bifurcating before passing in two fissures upon the squamous plate of the temporal bone In the second, the history is far from clear, but it seems that the fracture was caused by the compression of a cartwheel passing across the forehead The fracture is meridional and exactly like several in the next class

Class C^2 *Fractures caused by a compression in a longitudinal direction experimental* Of these I have nine cases Six show meridional fissures One divides the skull from front to back over the vault Three divides the skull to an equal extent through the base, passing round the foramen magnum In two there are two independent fissures In one of these cases one of the two fissures is not meridional Three of the cases show complicated fissures which may be due more to crushing than to bursting

Class D^1 *Fractures from blows on the parietal region* Of these I have only four cases All show meridional fissures Three pass straight down to the apex of the petrous bone, and one passes also up to the vertex

Class D *Fractures caused by falls striking on the parietal region* Of these I have fifteen cases, in all of which I think the fractures may be considered meridional Four pass along the horizontal equator of the skull Seven are transverse, three crossing the base from side to side, two going half way across, one involving only the ends of the petrous bone, and one passing across the vault at the back part of the parietal bones, and then passing forward to the base Four are diagonal, two of them passing the sella turcica

Class E^1 *Fractures caused by compression in a transverse* *direction accidental* Of these I have five cases In all, the fractures are transverse and meridional Two pass across the basi sphenoid bone and upward on both squamous bones In one both parietal bones are split independently, the fissures passing down through the petrous bone In one the coronal suture was separated, and a piece broken out of each parietal, beside an independent fracture of the occipital and petrous bones at the base on one side

CLASS E *Fractures caused by compression in a transverse direction experimental* Of these I have five cases In all the fissures are transverse and meridional In four the basi sphenoid is divided transversely, and in three the fissure involves also the temporal bones In one case the coronal suture is disarticulated

CLASS F *Fractures caused by falls striking on the temporo frontal region* Of these I have only two cases In one the fracture is meridional, in the other it is equatorial, and seems to illustrate the shoving of the posterior half of the skull over the anterior half by the impact of the spinal column on the base in an oblique direction

CLASS G *Fractures caused by compression in a diagonal direction experimental* Of these I have five cases In four the fissures are meridional, two being quite complicated In one case there is a separation of the posterior inferior angle of the parietal bone, and the dorsum of the sella turcica is broken off

CLASS H^1 *Fractures caused by blows on the vertex accidental* Of these I have six cases In all the fractures are meridional, in five they are transverse and in one longitudinal

CLASS H^2 *Fractures caused by blows on the vertex experimental* Of these I have three cases All of them show beautiful meridional fissures, one transverse and two longitudinal, one of the latter dividing the skull completely into halves

CLASS H^3 *Fractures caused by falls upon the vertex accidental* Of these I have seventeen cases In all the fissures are meridional and can, I think, be attributed to a burst In one the front half of the skull is divided longitudinally, and in one the posterior half is similarly divided In one the fissure divides the skull into halves longitudinally, in two it divides it into halves transversely In one the basilar artery was found caught in a transverse fissure of the basilar process of the occipital bone

CLASS J^1 *Fractures caused by falls upon the condyles (transmitted from feet accidental* Of these I have only three cases In two both posterior clinoid processes were broken off—which can be attributed to the lengthening of the antero posterior diameter of the skull—and there was a transverse fracture of the apex of the petrous bone In the third case there is only a longitudinal fissure of the horizontal plate of the ethmoid bone on one side

CLASS J *Fractures caused by blows on the condyles experimental* Of these I have four cases In all of them the dorsum of the sella turcica has been torn off by the elongation of the antero posterior diameter of the skull In two cases this is the only fracture In one case the whole base is also divided transversely, the fissure passing across the basilar process of the occipital bone In one case there are also three independent fissures, all transverse

CONCLUSION

The analysis of these 119 cases shows that 111 present fissures which correspond to what might be expected from an application of the principles of the "bursting theory," and only eight seem to contradict it This result, which has surprised me by its apparent completeness, seems to establish this theory by the best test which we can apply to it, so that it appears to rest upon a very firm tripod of reasoning, experiment, and clinical observation

I trust it will not be supposed that, in making so much of the bursting theory in this paper, I have overlooked the fact that there are fractures which cannot be accounted for by it There are some fractures in which the force applied is so great, and acts in such a manner, that the skull is crushed so as to hide any evidence of the play of its elastic properties, the fracture being of a comminuted sort, and there are others in which, as I have noted in passing, one segment of the skull seems to be shoved over the other by forces of pressure and counter-pressure which require some study before their mode of operation can be understood In this connection it is of importance to learn in any case the position which the skull has held in relation to the spinal column or to any body capable of exerting counter pressure No less is it important not to overlook the counter-pressure which is caused by the simple *vis inertiæ* of the skull, and its contents

But it would be impossible to speak of all the influences which may modify the strict application of any one theory in regard to fractures of the skull I have laid before you all the evidence which I now can in regard to this matter, and I must close with the expression of my own conviction that the supreme law governing the production of indirect fractures, is that which depends upon the fact that the skull is practically a hollow elastic case, approximately oval in shape, and which may be briefly formulated as follows When a sufficient force is applied to any curvilinear part of the skull, if this part do not give way immediately, the axis of the skull lying in the same line as that of the applied force is shortened, all the axis lying in planes at right angles to this line are correspondingly lengthened, with a proportional lengthening of their circumferences, and separation of their meridians, so that the direct depressing force is converted into an indirect disruptive force acting at right angles to the direction of the former The effect is to produce a fissure, or fissures, which will have a general meridional direction

The application of this law is subject to certain modifications due to the anatomical and architectonic peculiarities of the skull, its coverings and contents, and to certain exceptions due to the amount and velocity of the force applied as well as to the coming into play of peculiar counter forces

DR AGNEW remarked The paper just read is very interesting, and on a very interesting subject I must say, however, that I cannot agree with Dr Dulles as to the mode of fracture—the elasticity of the skull is too insignificant I still hold to the old vibratory theory I satisfied myself of the correctness of this by experimenting with ivory balls, suspended in such a manner as to touch different parts of the skull and watching the effect on these balls when the cranium was struck Fractures of the skull, in the vast majority of instances—when the force is concentrated on a very limited surface—occurs at the point of impact The force which gives rise to fractures at the base is usually a diffused one, and if applied at the vault of the skull travels to the base by the shortest route, the vibrations concentrating or focusing on certain fossæ in nearest relation with the seat of the applied violence

DR PACKARD said It seems to me that there are two points not mentioned by Dr Dulles which can hardly be left out of the account in considering the subject of these fractures One is the direction of the bony fibres—the intimate structure of the bones, as distinct from their mere shape The other is the momentum of the fracturing force Some ten years ago I reported a case in which a man was struck by a locomotive moving at such a speed that he was carried along in front of it for a distance of forty feet before he was flung over to the other track, receiving, among other instantly fatal injuries, a fracture which completely separated his skull into two portions, an anterior and a posterior Between such terrific violence as this and the blows or falls which are the usual causes of fracture of the skull, there are, of course, innumerable gradations, with corresponding influences on the lesions produced

Dr Dulles said It would not be possible to prepare a paper of the kind which I have presented this evening in such a way as to meet in advance all the objections which might be raised in regard to it, neither would it be possible in the time at our disposal for disscussion to answer all such objections I would only say briefly, that all that is claimed for the "bursting theory" is, that it seems to account for a very large number of indirect fractures Experience alone can determine the reliability of any theory, and while I have become convinced of the correctness of this one, time will decide the matter

In answer to the objection raised by Dr Formad, I would like to say that it is not really an objection, but rather supports the "bursting theory" The fractures passing horizontally, of which he speaks, are just as much meridional as though they passed vertically As I show you on this skull, any line passing round the surface in the shortest direction from pole to pole—that is, from the point of impact to the antipodal point, is meridional, and the line passing horizontally is as much meridional as any

Finally, in regard to the case about which Dr Formad asked a question, I would say that I do not now recall a single instance of the many which I have investigated, in which a stellate fracture was not a direct fracture, and I believe such an appearance is an indication that the fracture was caused by violence applied at that very spot This violence, of course, may be due to a blow on the point where the fracture appears, or to a fall in which the head strikes some resisting body at this point

PYOGENIC CYSTS AFTER OPERATION FOR FISTULA IN ANO

BY GEO N MONETTE, M D,

OF NEW ORLEANS LA

Resultant upon operations performed for fistula in ano, I have had under my observation two cases presenting localized pyogenic cysts I say cysts, because of the fact that, for a certain length of time, the secretion was not apparent, and when the cystic calibre was exhausted, there would be a flow of pus for several days, until it became encysted again Since both of these cases were operated upon by incision, I have been constrained to express a preference for the *ligature* in the destruction, curatively, of fistulous canals

The incised canal, with its continuity severed, is prone to heal too quickly to perfect the destruction of the pyogenic surface of the canal On the other hand, the ligature, being drawn taut, approximates the internal and external orifices at once, strangulates, and apparently makes a deep fistulous canal seem to be a superficial one Granulations supply the underlying pyogenic membrane with such rapidity that the same is readily detached, brought or pushed to the surface, and destroyed more completely

One of the cases I operated upon myself by incision, the wound healing, and apparently my patient was cured radically A cyst was superficially located on the nates, near the outlet of the canal, which had no connection with the rectum, nor was it deep in the muscular structures It was made manifest to me at once, that the source of this was in a portion of the pyogenic canal not having been completely destroyed by the operation, which is due to no fault of the operator, but to a tenacity of life in the pyogenic membrane forming the fistulous canal, which soon organizes, becomes encysted, and produces pus and develops into a cyst

The second case was operated upon by another physician (since deceased), with identical complications I probed the depth of this case, and found that the cavity was one fourth of an inch only, and of course not having any connection with the rectal canal, nor communicating with any remote pyogenic surface, membrane or canal

The treatment of such cases is patent first, we can but destroy the pyogenic surface by cauterization, thereby promoting granulation, filling up the cavity until the continuity of the integument is reestablished

A CASE OF URINARY UMBILICAL FISTULA THROUGH A PATENT URACHUS

BY J H YARNALL, M D,

OF GEORGETOWN, D C

Every physician now and then is confronted with anomalous constructions of various parts and organs of the human body, and which are always of more or less interest to the medical student Especially are these irregularities interesting when the anomaly is striking and rare, and then do they become worthy of record by adding to the curiosities of medical experience

I was called, on December 10, to see Joseph W, a colored infant about five weeks old, who, as the father reported, "was passing his water through his belly," and on close inspection such I found was literally the truth, for with every cry and struggle of the child, urine oozed through the umbilicus The child had been born at full term, and was of good size and well nourished, but since its birth its mother had noticed that it was impossible to keep the child clean and dry, and on closer inspection she observed that water would dribble from the umbilicus, and at times would a large stream be thrown out All doubt to my mind as to whether the urethra was pervious or no, was soon dissipated by a copious stream *per vias naturales* It was very obvious from these conditions, that the fibro muscular ligament passing from the fundus of the bladder to the umbilicus, and known as the urachus, had persisted in its fœtal form of a duct The umbilicus itself was slightly hypertrophied and indurated, and also excoriated, as was also the surrounding integument to a less degree Upon the umbilicus was a small, dark red, conical-shaped tumor, with its apex external, and it was from a small discernible orifice in this apex that the urine was passed I was able to pass through this opening a small gum catheter, in the direction of the linea alba, and into the bladder

On questioning the midwife who presided at the birth of this child, she informed me that the cord was larger than usual, and that it appeared to consist of two portions, separated by a web, and that it did not separate readily, and when separation occurred the little conical tumor was left, through which the urine was passed

The treatment applied was very simple, and the desired result quickly attained At first pressure was made over the umbilicus by large cork, held in position by a bandage of adhesive plaster, this was left on for three days, and during this time the urine continued to well around the cork I then applied sulphate of copper thoroughly over the surface of the tumor, and continued the pressure by bandage, and after three more applications of the caustic had the pleasure, two weeks after my first visit, of seeing the urine passed wholly through its proper canal, and the umbilicus resume its normal appearance

Dr Guéniot,[1] in a summary of seven cases of patient researches, one of which occurred in his own practice, shows that the treatment of all these cases by pressure and caustics alone, was futile, and in the three in which a cure was obtained the ligature around and through the tumor was used Dr R G Cabell,[2] of Virginia, reported a case of this deformity shown him as a curiosity, of a mulatto girl of fifteen years, and he says she "experienced no uneasiness or inconvenience from this unnatural passage to her bladder," for "she could at her pleasure evacuate urine by either channel "

The last case which I have seen recorded was by Dr Charles B Waller,[3] of the Rotherham Hospital, Yorkshire, England The patient was a male child five months old, and through the urachus he was able to pass a No 8 silver catheter The treatment pursued was the dissecting out of the urachus, ligating, dividing and dropping the end into the abdominal cavity After slight febrile disturbance the patient was discharged cured, on the sixteenth day after entering the hospital Previous to the operation pressure and caustics had been tried without effect In conclusion, I would state that I report my case simply as a remarkable vagary of nature

MEDICAL PROGRESS

URETHAN AND HYPNONE —Urethan is the æthylic ether of carbaminic acid, and its chemical composition may be represented by the formula $C_3H NO$ Fortunately, it has no odor and no disagreeable taste It may be obtained in beautiful white crystals, which are freely soluble in water Its action on man has been investigated by Jolly, Kobert, and von Jaksch, of Vienna Von Jaksch's observations were made on twenty patients suffering from various forms of insomnia His first experiments were with doses of ¼ of a gramme, or about 4 grains, but this was insufficient to produce any distinct hypnotic action He then increased the dose to nearly 8 grains, and found that this usually sufficed to produce several hours' good sound sleep In a patient suffering from hemiplegia associated with disease of the mitral valve, whose general condition contra indicated the employment of morphine or chloral, it answered admirably, giving a good night's rest without any disagreeable after effects Another patient, suffering from a painful aortic aneurism with persistent insomnia, was given a dose at 6 P M , with little or no effect, whilst another dose administered at 11 P M , gave calm refreshing sleep until 3 the next morning Dr von Jaksch made over one hundred observations with the drug, and is enthusiastic in its praise It proved most successful in simple uncomplicated cases, and was of comparatively little value when the patient suffered from acute pain He states that it is particularly suitable for administration to children, the absence of disagreeable taste being a very great advantage A short time since, Dr Sundby, of Birmingham, recorded two cases of cardiac insomnia treated successfully by two grain doses of urethan, given at bedtime in solution in water One of these was a case of aortic and mitral incompetence, with conjestion of the lungs, hæmoptysis, pleural effusion, and œdema of the legs The patient, as soon as he fell asleep, awoke with a dreadful feeling of suffocation, and for three nights had little or no rest, but subsequently, with the aid of urethan, he slept well and his condition greatly improved The other case was one of cardiac dilatation, with mitral incompetence, the heart's action being very feeble and irregular The patient had not slept for many nights, but urethan produced the desired effect, and she soon slept soundly

DR A S MYRTLE says Since October, I have been using urethan in a variety of cases with satisfactory results I have used it in over fifty cases as a sedative and hypnotic, and my experience of its action encourages me to recommend the drug to the readers of the *British Medical Journal*, believing that, in certain cases, it will prove of great value The cases in which I have prescribed it were of the usual run of every day practice, where a sedative or hypnotic was required, general restlessness, sleeplessness, neuralgia, catarrh, certain forms of skin affections with great irritation, also rheumatism and gout Many of my patients had some peculiarity of constitution which prevented the use of opiates of the usual type, and it is in this special class that I think urethan will prove of great value One gentleman, who had suffered from insomnia for weeks, and who cannot tolerate opium or chloral, took 15 grains at bedtime with the most perfect result He wrote to me and said, "The sleep caused was the most pleasant and momentum of the fracturing force Some ten years ago I reported a case in which a man was struck by a locomotive moving at such a speed that he was carried along in front of it for a distance of forty feet before he was flung over to the other track, receiving, among other instantly fatal injuries, a fracture which completely separated his skull into two portions, an anterior and a posterior Between such terrific violence as this and the blows or falls which are the usual causes of fracture of the skull, there are, of course, innumerable gradations, with corresponding influences on the lesions produced

[3] Medical Bulletin Philadelphia December 1885

Dr Dulles said It would not be possible to prepare a paper of the kind which I have presented this evening in such a way as to meet in advance all the objections which might be raised in regard to it, neither would it be possible in the time at our disposal for disscussion to answer all such objections I would only say briefly, that all that is claimed for the "bursting theory" is, that it seems to account for a very large number of indirect fractures Experience alone can determine the reliability of any theory, and while I have become convinced of the correctness of this one, time will decide the matter

In answer to the objection raised by Dr Formad, I would like to say that it is not really an objection, but rather supports the "bursting theory" The fractures passing horizontally, of which he speaks, are just as much meridional as though they passed vertically As I show you on this skull, any line passing round the surface in the shortest direction from pole to pole—that is, from the point of impact to the antipodal point, is meridional, and the line passing horizontally is as much meridional as any

Finally, in regard to the case about which Dr Formad asked a question, I would say that I do not now recall a single instance of the many which I have investigated, in which a stellate fracture was not a direct fracture, and I believe such an appearance is an indication that the fracture was caused by violence applied at that very spot This violence, of course, may be due to a blow on the point where the fracture appears, or to a fall in which the head strikes some resisting body at this point

PYOGENIC CYSTS AFTER OPERATION FOR FISTULA IN ANO

BY GEO N MONETTE, M D,

OF NEW ORLEANS, LA

Resultant upon operations performed for fistula in ano, I have had under my observation two cases presenting localized pyogenic cysts I say cysts, because of the fact that, for a certain length of time, the secretion was not apparent, and when the cystic calibre was exhausted, there would be a flow of pus for several days, until it became encysted again Since both of these cases were operated upon by incision, I have been constrained to express a preference for the *ligature* in the destruction, curatively, of fistulous canals

The incised canal, with its continuity severed, is prone to heal too quickly to perfect the destruction of the pyogenic surface of the canal On the other hand, the ligature, being drawn taut, approximates the internal and external orifices at once, strangulates, and apparently makes a deep fistulous canal seem to be a superficial one Granulations supply the underlying pyogenic membrane with such rapidity that the same is readily detached, brought or pushed to the surface, and destroyed more completely

One of the cases I operated upon myself by incision, the wound healing, and apparently my patient was cured radically A cyst was superficially located on the nates, near the outlet of the canal, which had no connection with the rectum, nor was it deep in the muscular structures It was made manifest to me at once, that the source of this was in a portion of the pyogenic canal not having been completely destroyed by the operation, which is due to no fault of the operator, but to a tenacity of life in the pyogenic membrane forming the fistulous canal, which soon organizes, becomes encysted, and produces pus and develops into a cyst

The second case was operated upon by another physician (since deceased), with identical complications I probed the depth of this case, and found that the cavity was one fourth of an inch only, and of course not having any connection with the rectal canal, nor communicating with any remote pyogenic surface, membrane or canal

The treatment of such cases is patent first, we can but destroy the pyogenic surface by cauterization, thereby promoting granulation, filling up the cavity until the continuity of the integument is reestablished

A CASE OF URINARY UMBILICAL FISTULA THROUGH A PATENT URACHUS

BY J H YARNALL, M D,

OF GEORGETOWN D C

Every physician now and then is confronted with anomalous constructions of various parts and organs of the human body, and which are always of more or less interest to the medical student Especially are these irregularities interesting when the anomaly is striking and rare, and then do they become worthy of record by adding to the curiosities of medical experience

I was called, on December 10, to see Joseph W, a colored infant about five weeks old, who, as the father reported, "was passing his water through his belly," and on close inspection such I found was literally the truth, for with every cry and struggle of the child, urine oozed through the umbilicus The child had been born at full term, and was of good size and well nourished, but since its birth its mother had noticed that it was impossible to keep the child clean and dry, and on closer inspection she observed that water would dribble from the umbilicus, and at times would a large stream be thrown out All doubt to my mind as to whether the urethra was pervious or no, was soon dissipated by a copious stream *per vias naturales* It was very obvious from these conditions, that the fibro muscular ligament passing from the fundus of the bladder to the umbilicus, and known as the urachus, had persisted in its fœtal form of a duct The umbilicus itself was slightly hypertrophied and indurated, and also excoriated, as was also the surrounding integument to a less degree Upon the umbilicus was a small, dark red, conical shaped tumor, with its apex external, and it was from a small discernible orifice in this apex that the urine was passed I was able to pass through this opening a small gum catheter, in the direction of the linea alba, and into the bladder

On questioning the midwife who presided at the birth of this child, she informed me that the cord was larger than usual, and that it appeared to consist of two portions, separated by a web, and that it did not separate readily, and when separation occurred the little conical tumor was left, through which the urine was passed

The treatment applied was very simple, and the desired result quickly attained At first pressure was made over the umbilicus by large cork, held in position by a bandage of adhesive plaster, this was left on for three days, and during this time the urine continued to well around the cork I then applied sulphate of copper thoroughly over the surface of the tumor, and continued the pressure by bandage, and after three more applications of the caustic had the pleasure, two weeks after my first visit, of seeing the urine passed wholly through its proper canal, and the umbilicus resume its normal appearance

Dr Guéniot,[1] in a summary of seven cases of patient researches, one of which occurred in his own practice, shows that the treatment of all these cases by pressure and caustics alone, was futile, and in the three in which a cure was obtained the ligature around and through the tumor was used Dr R G Cabell,[2] of Virginia, reported a case of this deformity shown him as a curiosity, of a mulatto girl of fifteen years, and he says she "experienced no uneasiness or inconvenience from this unnatural passage to her bladder," for "she could at her pleasure evacuate urine by either channel "

The last case which I have seen recorded was by Dr Charles B Waller,[3] of the Rotherham Hospital, Yorkshire, England The patient was a male child five months old, and through the urachus he was able to pass a No 8 silver catheter The treatment pursued was the dissecting out of the urachus, ligating, dividing and dropping the end into the abdominal cavity After slight febrile disturbance the patient was discharged cured, on the sixteenth day after entering the hospital Previous to the operation pressure and caustics had been tried without effect In conclusion, I would state that I report my case simply as a remarkable vagary of nature

MEDICAL PROGRESS

URETHAN AND HYPNONE —Urethan is the ethylic ether of carbaminic acid, and its chemical composition may be represented by the formula C_3H_7NO Fortunately, it has no odor and no disagreeable taste It may be obtained in beautiful white crystals, which are freely soluble in water Its action on man has been investigated by Jolly, Kobert, and von Jaksch, of Vienna Von Jaksch's observations were made on twenty patients suffering from various forms of insomnia His first experiments were with doses of ¼ of a gramme, or about 4 grains, but this was insufficient to produce any distinct hypnotic action He then increased the dose to nearly 8 grains, and found that this usually sufficed to produce several hours' good sound sleep In a patient suffering from hemiplegia associated with disease of the mitral valve, whose general condition contra indicated the employment of morphine or chloral, it answered admirably, giving a good night's rest without any disagreeable after effects Another patient, suffering from a painful aortic aneurism with persistent insomnia, was given a dose at 6 P M, with little or no effect, whilst another dose administered at 11 P M, gave calm refreshing sleep until 3 the next morning Dr von Jaksch made over one hundred observations with the drug, and is enthusiastic in its praise It proved most successful in simple uncomplicated cases, and was of comparatively little value when the patient suffered from acute pain He states that it is particularly suitable for administration to children, the absence of disagreeable taste being a very great advantage A short time since, Dr Sundby, of Birmingham, recorded two cases of cardiac insomnia treated successfully by two-grain doses of urethan, given at bedtime in solution in water One of these was a case of aortic and mitral incompetence, with conjestion of the lungs, hæmoptysis, pleural effusion, and œdema of the legs The patient, as soon as he fell asleep, awoke with a dreadful feeling of suffocation, and for three nights had little or no rest, but subsequently, with the aid of urethan, he slept well and his condition greatly improved The other case was one of cardiac dilatation, with mitral incompetence, the heart's act on being very feeble and irregular The patient had not slept for many nights, but urethan produced the desired effect, and she soon slept soundly

DR A S MYRTLE says Since October, I have been using urethan in a variety of cases with satisfactory results I have used it in over fifty cases as a sedative and hypnotic, and my experience of its action encourages me to recommend the drug to the readers of the *British Medical Journal*, believing that, in certain cases, it will prove of great value The cases in which I have prescribed it were of the usual run of every day practice, where a sedative or hypnotic was required, general restlessness, sleeplessness, neuralgia, catarrh, certain forms of skin affections with great irritation, also rheumatism and gout Many of my patients had some peculiarity of constitution which prevented the use of opiates of the usual type, and it is in this special class that I think urethan will prove of great value One gentleman, who had suffered from insomnia for weeks, and who cannot tolerate opium or chloral, took 15 grains at bedtime with the most perfect result He wrote to me and said, "The sleep caused was the most pleasant and refreshing I awoke without a headache, with appetite for breakfast, and what was equally agreeable, there was no interruption to any of my functions" Similar testimony has been given by the majority of patients, who have taken full doses to produce sleep In smaller doses, its action is less marked, still it is decidedly calmative and agreeable, causing no unpleasant effect, such as nausea, flatulence, constipation or headache It does not effect the nerve-centres of circulation or respiration, but spends itself on the cerebrum It possesses, therefore, great advantages the older and valuable sedatives, which have certain evil influences, especially in exceptional cases Given in gout and rheumatism in full doses, alone or in combination, it has the great advantage over morphia of not interfering with the action of the bowels or kidneys, besides, it is not unpleasant to the taste, the only objection to it is its price, although that has been reduced 50 per cent since I gave my first dose three months ago

For the other new hypnotic, we have to thank Dr Dujardin-Beaumetz, who recently submitted to the Académie de Médicine of Paris the results of a series of observations on aceto phenone, or as it is more commonly called, hypnone This compound is prepared by the action of chloride of benzoyl on zinc methyl, or by distilling together a mixture of benzoate and acetate of calcium It is a colorless mobile liquid, having an odor not unlike oil of bitter almonds or cherry laurel water It has a very decided physiological action, for a cubic centimètre injected under the skin of a guinea pig produced a torpid comatose condition, from which the animal did not recover The respiration was quickened, the heart-beats became fewer in number, the animal started convulsively, gradually grew colder, and died To produce sleep, it should be given in doses of from 2 to 16 minims, and, if administered at bedtime, it uniformly produces a well marked hypnotic action It may be diluted with alcohol, ether, glycerine, but the best way to give it is in capsules It communicates to the breath a somewhat disagreeable odor, but its taste may be masked by syrup of orange flower or oil of sweet almonds Dr Dujardin-Beaumetz's observations have been fully confirmed both by Dr Constantine Paul and by Dr Huchard —*British Medical Journal*, February 20 1886

LEAD POISONING —DR SINCLAIR WHITE, the medical officer of health for Sheffield, has recently published an excellent and interesting report on the action of the Sheffield water on the lead communication pipe and its effects on the health of the community A number of cases of chronic lead poisoning occurred during last year amongst persons not engaged in any of the trades in which lead is used, analysis showing that the drinking-water in every case contained a sufficient amount of lead to account for the poisoning An examination of the water-supply led to the fact becoming known that the water of only some parts of the town contained lead to any appreciable extent Sheffield derives its water from two distinct sources, with separate systems of distribution, the first is from the hills around Redmires, which is collected in reservoirs near its origin, and and runs in a conduit to a reservoir at Crooke, known as Hadfield Reservoir, whence it is distributed to certain high lying districts, the other source is from the hills around Strines and Agden, which runs in a conduit to a reservoir known as Godfrey Reservoir, and is thence distributed to the two low lying parts of the town The persons who suffered from lead poisoning resided in the high lying districts The Redmires water is collected from moorland, the surface peat varying in thickness from a few inches to several feet, and beneath this are shale and mill stone grit of the carboniferous system of rocks, both the peat and the shale contain iron pyrites, and the water was distinctly acid in reaction, the acidity being most intense in the higher portion of the collecting grounds The Strines and Agden water was not acid The cause of acidity in the Redmires water was the subject of careful investigation, and it was found possible that this had resulted, firstly, from the action of soft water on the iron pyrites, giving origin to free sulphuric acid, secondly, from ulmic and humic acids, which are caused by the decomposition of vegetable substances, thirdly, from the atmosphere, which contains large quantities of sulphurous acid, the result of the large consumption of coal in the town Assuming that the first two possible causes had been in force, the impregnation of the Redmires water is explained on the ground that this neighborhood contains iron pyrites, while the water from Strines and Agden, from containing more alumina, which would neutralize the acid, would give less evidence of the presence of free acid A further analysis of water taken from sources where the water had passed through new and old lead pipes showed the former contained a much larger amount of lead than the latter, the former containing from 0 14 to 0 61 grain per gallon, whereas the latter contained from 0 14 to 0 42 grain per gallon Again, long pipes led to greater pollution of the water than short ones, and the length of time the water had stood in the pipes was also directly related to the amount of lead contained The report ends with a statement of the results of filtration carbon and spongy iron filters removing all traces of lead —*Lancet*, March 13, 1886

LEAD POISONING BY HOUSEHOLD UTENSILS —The German Parliament has now under consideration a Bill which is intended to regulate the employment of lead in the manufacture of cooking and other domestic utensils, and so to diminish the risk of poisoning by that metal The provisions of this measure certainly do not err on the side of leniency They forbid the use of vessels containing more than 10 per cent of lead in their composition for the above purposes No alloy with over 1 per cent may be used in coating iron articles used in cookery Solder may consist of lead to one tenth of its amount, but no more Enamels into which lead enters are treated with equal stringency The effect of this Bill, if it be passed, will be to obliterate the legal existence of pewter and of soft solder as at present made, since these alloys contain from one half to one-fourth of their weight of lead One fact which it brings into prominence is that lead-poisoning in Germany appears to arise from other causes besides those to which it is commonly attributed in this country Cases of this kind among ourselves are usually found in the persons of those who are actually engaged in handling lead or its compounds in their daily occupation Plumbers, painters, glass blowers, glaziers, potters and enamel-card makers furnish the majority of those who suffer from plumbism When this disorder appears in the household, new paint in the walls or the lead work of the water service affords a clue to its detection It is comparatively rare to find in these days that pewter pots or cooking utensils are at fault This may be because glass is used on the whole far more frequently than pewter in the liquor trade, while in the kitchen those vessels the contents of which are most likely to become contaminated with lead in the solder—such, for example, as preserving pans—are usually made of brass or copper (which is kept well burnished), and present a relatively trifling soldered surface, or are lined with porcelain The water used in cooking also acts as a protective, since the lime salts contained in it tend to prevent the solution of lead The proposed German legislation on this subject is very perfect in theory so far as it goes Possibly it may be called for by the teaching of experience In this country it would probably be found to be needlessly severe, and would not cover the chief causes of the evil which it is intended to meet We do not see how it can do this even in Germany, unless measures of equal rigor be adopted to control the use of lead in manufactures and in its other domestic applications The introduction of these further restrictions might fitly exercise the judgment of our own as well as foreign legislators —*Lancet*, February 13, 1886

THE TREATMENT OF OLD CORNEAL OPACITIES —In the last number of *Archiv fur Ophthalmologie*, Dr Dantziger advocates the treatment of old opacities of the cornea by friction performed daily, and continued for two or three months if necessary When the opacity is of moderate size, but of considerable density, it is recommended that it should first be scraped away, and the friction, or "massage," commenced as soon as the epithelium has been reformed The scraping is performed with a Graefe's knife, used in the manner in which one scrapes away a blot with a penknife Antiseptic precautions are used, and iodoform is applied as a dressing, cocaine produces sufficient anæsthesia Atropine and warm fomentations are used if the reaction be very great, by the fifth to the eighth day the epithelium has generally been reproduced, and the "massage" is then commenced A minute piece of Pagenstecher's ointment is introduced, and the upper lid is then moved from side to side over the cornea with the fore finger, with a rapid to and fro movement, for about half a minute Some hyperæmia is produced, which should not last more than a few minutes, if it last as long as half an hour, the treatment must be used cautiously, and may have it to be abandoned The author gives a detailed account of ten cases, in four of which the friction was preceded by scraping With the exception of three, all were opacities which had existed in a stationary condition for more than three years, and in all except one (in which the whole cornea presented a greyish opacity) there was a very great improvement in vision, sometimes without any obvious clearing of the cornea An improvement from $\frac{20}{200}$ to $\frac{20}{60}$ in three months would, perhaps, about represent the average result of the cases, but in some it was much better Those who know how very intractable these cases are under ordinary treatment, will welcome any method which offers a reasonable prospect of ameliorating their condition, and should these results be borne out by wider experience, a very valuable addition will have been made to the resources of ophthalmic surgery —*British Medical Journal*, February 20, 1886

SALICYLATE OF LITHIUM IN RHEUMATISM —VULPIAN read before the Paris Academy of Medicine recently a paper in which he claimed certain advantages of salicylate of lythium over the salicylate of sodium We abstract without comment some of the principal points of his paper, as found in the *Deutsche Medizinal Zeitung* of January 14, 1886

In spite of the acknowledged specific influence which salicylate of sodium exercises over the rheumatic process in general, every practitioner has met cases which proved absolutely refractory to this medication In some forms of rheumatism, such as the gonorrhœal, in the subcutaneous articular and chronic articular, the sodium salt has little if any power In these forms the salicylate of lithium has, in the hands of Vulpian, given fair results, and proven by all means superior to the salicylate of sodium Wherever the fibrous tissues are first and prominently affected, the lithium salt appears to act better In some chronic cases, in which the sodium salt had been exhibited for a long time without the slightest effect, salicylate of lithium gave relief in ten to fourteen days, removing pain, swelling and functional disturbance Improvement was also obtained in some very advanced cases marked by semi anchylosis and deformities The salt is easily soluble in water, has an agreeable taste, and may be given in doses of 7 grains The daily ingestion ought not to exceed 1 drachm The drug is, however, by no means free from unpleasant after effects, though patients who were treated by both the sodium and the litheum salt gave the latter the preference —*Therapeutic Gazette*, March 15, 1886

NERVOUS TROUBLES IN SLOW MERCURIAL INTOXICATION —1 Slow mercurial poisoning gives rise to a certain number of nervous troubles which constitute the greater part of its symptomatology

2 These nervous troubles can be attributed, in part, to the presence of mercury in the nervous centres, where it has frequently been found, and in part to lesions of the cerebro spinal system, which have been described by Wising One of the most curious characteristics of these lesions is the persistence of the axis cylinder in the altered regions This last condition is found in the lesions of sclerosis in plaques, which, moreover, in its clinical features

refreshing I awoke without a headache, with appetite for breakfast, and what was equally agreeable, there was no interruption to any of my functions" Similar testimony has been given by the majority of patients, who have taken full doses to produce sleep In smaller doses, its action is less marked, still it is decidedly calmative and agreeable, causing no unpleasant effect, such as nausea, flatulence, constipation or headache It does not effect the nerve-centres of circulation or respiration, but spends itself on the cerebrum It possesses, therefore, great advantages the older and valuable sedatives, which have certain evil influences, especially in exceptional cases Given in gout and rheumatism in full doses, alone or in combination, it has the great advantage over morphia of not interfering with the action of the bowels or kidneys, besides, it is not unpleasant to the taste, the only objection to it is its price, although that has been reduced 50 per cent since I gave my first dose three months ago

For the other new hypnotic, we have to thank Dr Dujardin-Beaumetz, who recently submitted to the Academie de Médicine of Paris the results of a series of observations on aceto-phenone, or as it is more commonly called, hypnone This compound is prepared by the action of chloride of benzoyl on zinc methyl, or by distilling together a mixture of benzoate and acetate of calcium It is a colorless mobile liquid, having an odor not unlike oil of bitter almonds or cherry laurel water It has a very decided physiological action, for a cubic centimètre injected under the skin of a guinea pig produced a torpid comatose condition, from which the animal did not recover The respiration was quickened, the heart-beats became fewer in number, the animal started convulsively, gradually grew colder, and died To produce sleep, it should be given in doses of from 2 to 16 minims, and, if administered at bedtime, it uniformly produces a well marked hypnotic action It may be diluted with alcohol, ether, glycerine, but the best way to give it is in capsules It communicates to the breath a somewhat disagreeable odor, but its taste may be masked by syrup of orange flower or oil of sweet almonds Dr Dujardin-Beaumetz's observations have been fully confirmed both by Dr Constantine Paul and by Dr Huchard —*British Medical Journal*, February 20 1886

LEAD POISONING —DR SINCLAIR WHITE, the medical officer of health for Sheffield, has recently published an excellent and interesting report on the action of the Sheffield water on the lead communication-pipe and its effects on the health of the community A number of cases of chronic lead poisoning occurred during last year amongst persons not engaged in any of the trades in which lead is used, analysis showing that the drinking-water in every case contained a sufficient amount of lead to account for the poisoning An examination of the water-supply led to the fact becoming known that the water of only some parts of the town contained lead to any appreciable extent Sheffield derives its water from two distinct sources, with separate systems of distribution, the first is from the hills around Redmires, which is collected in reservoirs near its origin, and and runs in a conduit to a reservoir at Crooke, known as Hadfield Reservoir, whence it is distributed to certain high lying districts, the other source is from the hills around Strines and Agden, which runs in a conduit to a reservoir known as Godfrey Reservoir, and is thence distributed to the two low lying parts of the town The persons who suffered from lead poisoning resided in the high lying districts The Redmires water is collected from moorland, the surface peat varying in thickness from a few inches to several feet, and beneath this are shale and mill stone grit of the carboniferous system of rocks, both the peat and the shale contain iron pyrites, and the water was distinctly acid in reaction, the acidity being most intense in the higher portion of the collecting grounds The Strines and Agden water was not acid The cause of acidity in the Redmires water was the subject of careful investigation, and it was found possible that this had resulted, firstly, from the action of soft water on the iron pyrites, giving origin to free sulphuric acid, secondly, from ulmic and humic acids, which are caused by the decomposition of vegetable substances, thirdly, from the atmosphere, which contains large quantities of sulphurous acid, the result of the large consumption of coal in the town Assuming that the first two possible causes had been in force, the impregnation of the Redmires water is explained on the ground that this neighborhood contains iron pyrites, while the water from Strines and Agden, from containing more alumina, which would neutralize the acid, would give less evidence of the presence of free acid A further analysis of water taken from sources where the water had passed through new and old lead pipes showed the former contained a much larger amount of lead than the latter, the former containing from 0 14 to 0 61 grain per gallon, whereas the latter contained from 0 14 to 0 42 grain per gallon Again, long pipes led to greater pollution of the water than short ones, and the length of time the water had stood in the pipes was also directly related to the amount of lead contained The report ends with a statement of the results of filtration carbon and spongy iron filters removing all traces of lead —*Lancet*, March 13, 1886

LEAD POISONING BY HOUSEHOLD UTENSILS —The German Parliament has now under consideration a Bill which is intended to regulate the employment of lead in the manufacture of cooking and other domestic utensils, and so to diminish the risk of poisoning by that metal The provisions of this measure certainly do not err on the side of leniency They forbid the use of vessels containing more than 10 per cent of lead in their composition for the above purposes No alloy with over 1 per cent may be used in coating iron articles used in cookery Solder may consist of lead to one tenth of its amount, but no more Enamels into which lead enters are treated with equal stringency The effect of this Bill, if it be passed, will be to obliterate the legal existence of pewter and of soft solder as at present made, since these alloys contain from one-half- to one-fourth of their weight of lead One fact which it brings into prominence is that lead-poisoning in Germany appears to arise from other causes besides those to which it is commonly attributed in this country. Cases of this kind among ourselves are usually found in the persons of those who are actually engaged in handling lead or its compounds in their daily occupation. Plumbers, painters, glass blowers, glaziers, potters and enamel-card makers furnish the majority of those who suffer from plumbism. When this disorder appears in the household, new paint in the walls or the lead work of the water service affords a clue to its detection. It is comparatively rare to find in these days that pewter pots or cooking utensils are at fault. This may be because glass is used on the whole far more frequently than pewter in the liquor trade, while in the kitchen those vessels the contents of which are most likely to become contaminated with lead in the solder—such, for example, as preserving pans—are usually made of brass or copper (which is kept well burnished), and present a relatively trifling soldered surface, or are lined with porcelain. The water used in cooking also acts as a protective, since the lime salts contained in it tend to prevent the solution of lead. The proposed German legislation on this subject is very perfect in theory so far as it goes. Possibly it may be called for by the teaching of experience. In this country it would probably be found to be needlessly severe, and would not cover the chief causes of the evil which it is intended to meet. We do not see how it can do this even in Germany, unless measures of equal rigor be adopted to control the use of lead in manufactures and in its other domestic applications. The introduction of these further restrictions might fitly exercise the judgment of our own as well as foreign legislators.—*Lancet*, February 13, 1886.

The Treatment of Old Corneal Opacities.—In the last number of *Archiv fur Ophthalmologie*, Dr. Dantziger advocates the treatment of old opacities of the cornea by friction performed daily, and continued for two or three months if necessary. When the opacity is of moderate size, but of considerable density, it is recommended that it should first be scraped away, and the friction, or "massage," commenced as soon as the epithelium has been reformed. The scraping is performed with a Graefe's knife, used in the manner in which one scrapes away a blot with a penknife. Antiseptic precautions are used, and iodoform is applied as a dressing; cocaine produces sufficient anæsthesia. Atropine and warm fomentations are used if the reaction be very great; by the fifth to the eighth day the epithelium has generally been reproduced, and the "massage" is then commenced. A minute piece of Pagenstecher's ointment is introduced, and the upper lid is then moved from side to side over the cornea with the forefinger, with a rapid to and fro movement, for about half a minute. Some hyperæmia is produced, which should not last more than a few minutes; if it last as long as half an hour, the treatment must be used cautiously, and may have it to be abandoned. The author gives a detailed account of ten cases, in four of which the friction was preceded by scraping. With the exception of three, all were opacities which had existed in a stationary condition for more than three years, and in all except one (in which the whole cornea presented a greyish opacity) there was a very great improvement in vision, sometimes without any obvious clearing of the cornea. An improvement from $\frac{20}{200}$ to $\frac{20}{60}$ in three months would, perhaps, about represent the average result of the cases, but in some it was much better. Those who know how very intractable these cases are under ordinary treatment, will welcome any method which offers a reasonable prospect of ameliorating their condition; and should these results be borne out by wider experience, a very valuable addition will have been made to the resources of ophthalmic surgery.—*British Medical Journal*, February 20, 1886.

Salicylate of Lithium in Rheumatism.—Vulpian read before the Paris Academy of Medicine recently a paper in which he claimed certain advantages of salicylate of lythium over the salicylate of sodium. We abstract without comment some of the principal points of his paper, as found in the *Deutsche Medizinal Zeitung* of January 14, 1886.

In spite of the acknowledged specific influence which salicylate of sodium exercises over the rheumatic process in general, every practitioner has met cases which proved absolutely refractory to this medication. In some forms of rheumatism, such as the gonorrhœal, in the subcutaneous articular and chronic articular, the sodium salt has little if any power. In these forms the salicylate of lithium has, in the hands of Vulpian, given fair results, and proven by all means superior to the salicylate of sodium. Wherever the fibrous tissues are first and prominently affected, the lithium salt appears to act better. In some chronic cases, in which the sodium salt had been exhibited for a long time without the slightest effect, salicylate of lithium gave relief in ten to fourteen days, removing pain, swelling and functional disturbance. Improvement was also obtained in some very advanced cases marked by semi anchylosis and deformities. The salt is easily soluble in water, has an agreeable taste, and may be given in doses of 7 grains. The daily ingestion ought not to exceed 1 drachm. The drug is, however, by no means free from unpleasant after effects, though patients who were treated by both the sodium and the litheum salt gave the latter the preference.—*Therapeutic Gazette*, March 15, 1886.

Nervous Troubles in Slow Mercurial Intoxication.—1. Slow mercurial poisoning gives rise to a certain number of nervous troubles which constitute the greater part of its symptomatology.

2. These nervous troubles can be attributed, in part, to the presence of mercury in the nervous centres, where it has frequently been found, and in part to lesions of the cerebro spinal system, which have been described by Wising. One of the most curious characteristics of these lesions is the persistence of the axis cylinder in the altered regions. This last condition is found in the lesions of sclerosis in plaques, which, moreover, in its clinical features

shows some analogies with cerebro-spinal hydrargyrosis

3 The nervous troubles of hydrargyrosis are

a Disturbances of motion trembling analogous to that of sclerosis in plaques, convulsive phenomena of various kinds (cramps, epileptiform attacks, etc), choreic movements, apoplectiform ictus, paralyses presenting the features of paralysis of cerebral origin

b Disturbances of sensibility anæsthesia presenting *the features of anæsthesia of cerebral origin*, painful phenomena of which the most constant are *the arthralgias and* cephalalgias

c Disturbances of a psychical nature which are at first excessively emotional disturbances of sleep, vertigo, and, toward the last, dementia very much resembling senile dementia

4 In general, these nervous orders persist for a very long time, they may be greatly benefited, but only rarely can an absolute cure be obtained — Phillipe Marechal, *These de Paris*, 1885 —*Jour Cutaneous and Venereal Diseases,* March, 1886

A Specific for the Treatment of Hernia — Dr Doroteo de Armas publishes an article in the *Union Medicale de Caraccas* (*Bull Gen de Ther*, No 28, 1885), in which he claims that the peasants of Venezuela produce a radical cure of hernia by means of a parasitic plant which grows on the *Bowdichia virgiloides* The boughs of this parasitic plant are stripped of their leaves, and then scraped with a sharp instrument so as to remove all the inactive portions of the bark, the remainder is then chopped up and mixed with water to form a semisolid paste After the lapse of some time an extractive matter separates, which is at first greenish, but then becomes almost black It is elastic, semi solid, and capable of being drawn out in long filaments, which stick to the hands, and gradually harden when exposed to the air The mode of employment is to spread a thick layer of this substance on a piece of linen, and, after having well shaved the skin, to apply it over the hernial tumor, where it is maintained from forty days to two months Dr Armas refers to two cases of cure with which he is himself personally acquainted He believes that this mode of action is on the one side attributable to its contraction, and so renders it analogous in its application to a truss, and he believes, on the other hand, that it exerts special influence over the hernial rings —*Therapeutic Gazette,* March 15, 1886

Benzoate of Cocaine—Dr A Bignon considers the benzoate superior to all other salts of cocaine as a local anæsthetic Benzoic acid is the natural synergist of cocaine, since it is one of the products of its decomposition, but, when combined with it, increases its stability Moreover, its antiseptic property is an advantage, and the benzoate in solution has a decided odor of the coca leaf Mention is made of epithelioma of the tongue, who could neither eat, talk, nor sleep without using cocaine The muriate only enabled him to sleep for an hour at a time, but the benzoate secured four hours of continuous sleep The experiment was repeated many times and invariably with the same result He states that, whereas an application of the neutral hydrochlorate caused a painful sensation before anæsthesia was established, nothing of the sort occurred when the benzoate was used The benzoate may be prepared extemporaneously in solution by using one part of benzoic acid to three parts of cocaine —*New York Medical Journal Journal* March 13, 1886

Muriate of Thebaine in some Affections of the Optic Nerve —Dr Bono says that thebaine is an excellent myotic, similar to eserine, but producing less spasm and myosis One drop of a 1–40 solution produces its effect in half an hour, the effect passing off in four or five hours He believes that thebaine will prove very useful in the following cases

1 In alcoholic and nicotinic amblyopia

2 In detachments of the retina

3 In incipient progressive general paralysis, with limitation of the visual field and atrophy of the optic nerve

4 In the anæmics and convalescents of grave diseases (typhoid, diabetes, malaria, etc) with visual troubles

5 In descending atrophy of the optic nerve

6 In neuro retinal affections of syphilitics, use being made at the same time of mercurial frictions, with iodide of potassium internally —*Nouveaux Remedes,* March 1, 1886

Intra Venous Injections of Iodine —Dr Van der Heyden, on the assumption that infection of deep closed tissues is due to bacteria, and that these organisms are especially sensitive to the action of iodine, has used the following mixture as an intravenous injection in certain cases

Iodine	1 part
Iodide of sodium	2 parts
Distilled water	7 "
M	

The amount for one injection is 10 grammes

The first injection was made in a case of typhoid fever, in which the temperature was very high It fell immediately, and did not go up again In two cases of cholera, at the beginning, the injection produced a favorable effect In another case, in which the algid period was very pronounced, it was of no avail In three cases of leprosy there was marked amelioration —*Nouveaux Remedes*, March 1, 1886

Congenital Tuberculosis —An eight months' fœtus was taken from a cow, the subject of advanced tuberculosis, by Dr Johne The placenta and uterus were free from tuberculous lesions, but in the lower lobe of the right lung a nodule the size of a pea was detected containing four caseous centres The bronchial glands were congested and also tuberculous The liver contained numerous gray granulations Microscopically the tubercular structure was confirmed, masses of epithelioid cells with giant corpuscles containing tubercular bacilli were discovered —*Lancet*, March 6, 1886

Address

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No 65 RANDOLPH STREET
CHICAGO ILLINOIS

SATURDAY, APRIL 3, 1886

TUESDAY, MAY 4, 1886

We have seen in several of our exchanges references to the next meeting of the American Medical Association as to take place on the *second* Tuesday in May, which may deceive some in regard to that meeting We think the error in date originated in an editorial in the *Courier-Journal*, of St Louis, several weeks since The meeting at St Louis will commence on the first Tuesday, May 4, 1886, as stated in the official notice of the Permanent Secretary Any of our exchanges which have made the error will confer a favor by making the correction as soon as possible

CHICAGO AS A CENTRE OF MEDICAL EDUCATION

Thirty seven years since, when the writer of this paragraph became a resident of Chicago, there was but one medical college in it, called the Rush Medical College, in honor of Dr Benjamin Rush, of Revolutionary fame Its annual lecture term was sixteen weeks, and its class of medical students numbered about 120 At its recent annual Commencement exercises the same college conferred the degree of Doctor of Medicine on 165 students, and its whole class of matriculants was reported to be 410 Beside this college there have been added three other regular colleges, viz The Chicago Medical College, which is the Medical Department of the Northwestern University, the Chicago Woman's Hospital Medical College, and the College of Physicians and Surgeons At the recent annual public Commencements of these institutions the Chicago Medical College reports 120 matriculants and 39 graduates, the Woman's Hospital Medical College 60 matriculants and 17 graduates, and the College of Physicians and Surgeons 165 matriculants and 71 graduates, making a total of 755 matriculants and 292 graduates

Instead of the original annual term of sixteen weeks, at the present time the regular annual term of instruction is five months in all except the Chicago Medical College and the Woman's College, which require full six months of thoroughly graded instruction each year Thirty seven years since there was no organized hospital open for clinical instruction in Chicago, but during the past year the students of the several schools named have had access for systematic clinical instruction to no less than five important public hospitals for the sick, and to not less than three well patronized free dispensaries The attainment of a fair general education is required of each student before he is admitted to the medical colleges, and during the last eight or ten years the Chicago Medical College has required systematic practical work in the laboratories of chemistry, histology, and pathology as a part of the curriculum for graduation During the past college term the accommodations in the laboratories of histology and pathology have been sufficient for classes of thirty or more at the microscopes, under the direction of the professors or their demonstrators At the recent public Commencement of Rush Medical College it was announced that arrangements had been completed for requiring in future of her classes the same practical work in the departments of histology and pathology

If Chicago does not at this day rank with the first three cities of America in respect to population and commerce, the foregoing facts and figures show that she certainly does as a centre of medical education and scientific progress

PTOMAINES, LEUCOMAINES AND MICROBES—PUERPERAL SEPTICÆMIA

At the meeting of the Académie de Médecine, on February 23, a note was read from Mr Béchamp, of Lille, in which he takes MM Gautier and Peter to task on two or three points in regard to their recent papers on "Ptomaines and Leucomaines" The reading of the communication was followed by an interesting discussion on the part of MM Charpentier, Peter, and Verneuil M Bechamp's first point is as to a question of priority So long ago as May, 1871, he delivered a lecture before the Academy in which he said "The living being, filled with microzymes, bears in itself the essential elements of life, disease, death and total destruction And that this diversity in the results does not astonish us, the results are the same Our cells are constantly destroying themselves by a process of fermentations entirely analogous to those which follow death One may truly say that we putrefy unceasingly" This language in the light of further knowledge, and in conformity with the microbial theories, he now retracts "We neither putrefy nor ferment We are nourished, and what is called fermentation, and putrefaction, is only nutrition in the cellular beings and vibrios"

In the discussion on this subject M Charpentier called attention to the fact that M Trèlat had asked the opinion of obstetricians on certain facts concerning puerperal septicæmia, related by M Le Fort, and interpreted by M Peter in the sense of auto infection, or auto-typhysation, to use the favorite expression of the advocate of spontaneous generation M Charpentier confined his remarks strictly to a general consideration of puerperal septicæmia, and to certain facts advanced by his colleagues First, he said, we must consider one fact as absolutely incontrovertible to day "Puerperal septicæmia is the manfestation, under multiple forms, of an infection, of an intoxication of the lying-in woman It is always accompanied by the presence of microbes in the tissues of the woman so affected This puerperal septicæmia is essentially transmissible, and we may to day, thanks to antiseptic precautions, not only avoid this transmissibility, but even suppress the disease itself, so to speak The statistics of Maternities prove this From 10 to 15 per cent the mortality has fallen to 1 per cent in hospitals It would be nothing, I venture to say, if all the antiseptic precautions were to day and henceforth rigorously carried out"

But if *all* obstetricians be in accord, French and all others, in recognizing that puerperal septicæmia is the result of an infection, it is easily seen that a series of questions are naturally suggested 1 Can a lying in woman produce puerperal septicæmia in herself? Can she spontaneously create this morbid agent, whatever it be, which poisons her? Can she, in a word, produce auto infection, or, on the contrary, is this septic agent always transmitted, or caused by hetero infection? 2 Admitting that puerperal septicæmia is always the result of an infectious agent, what is the nature of this agent? What is to be understood by spontaneity in disease? Charpentier does not think it admissible to hold, with Peter and Béchamp, to the spontaneous development of bacteria, bacteria being only the evolution of microzymes This theory has been completely refuted, within the past two months, by Cornil Spontaneity is only apparent From an exclusively clinical point of view we can never know absolutely the exact source of infection It may be suspected with more or less probability, but can never be demonstrated except by the experimental method When there is a question of infection, whatever this infection may be, there are always two elements to be considered the infecting agent, and the soil upon which it is deposited The soil varies as the woman is in the pregnant or the lying in state The pregnant woman offers no soil for the microbe, but in the lying-in woman the conditions are extremely favorable When a woman, says Charpentier, is delivered without antiseptic precaution, and contracts a puerperal or septic affection, we can never affirm what is the source of the poison

Sometimes isolated cases of puerperal septicæmia are seen, which seem to be developed in spite of all precautions These are often cited as sporadic cases, without direct contagion by the genital organs being shown Are these cases infected by the uterine wound in spite of everything? Are they examples of auto-infection? These, says Charpentier, are insoluble hypotheses. One fact, however, is certain septicæmia is of microbial origin Would M Peter, who denies the influence of the microbe, neglect antiseptic precautions in the lying-in chamber? He attaches great importance to *soil*, seemingly forgetful that the most enthusiastic microbiologists give it almost the same, if not as great importance M Béchamp announces that he will soon make known the true theory of nutrition, and expose the physiological and chemical errors in the expression "vivre anaérobiquement on putrefactivement" of Gautier, errors as prejudicial to science as to medicine Our readers may therefore look for a continuation of this discussion and subject in an early issue of The Journal

SCHOOLS FOR CRIMINALS

A late issue of the *Philadelphia Record*, which, it will be remembered, is the newspaper which exposed the notorious "Dr Buchanan," contained some startling disclosures of gross mismanagement and brutality in the management of the schools or asylums for soldiers' orphans in the State of Pennsylvania These reports have been confirmed by an investigation conducted by the committee of the Grand Army of the Republic, and by the Governor of Pennsylvania in person There are at present eighteen such institutions in Pennsylvania, the number of orphans in them being about 2000, ranging in age from four to sixteen years While the State has no property interest in the schools, it pays annually $150 for each child ordered into them It is evident from the report of the committee that those who managed the schools did so with an eye only to the possible profits to be derived

At scarcely any of the eighteen schools and homes was there a satisfactory condition of affairs, while the management of those at Mount Joy and Mercer is disgraceful The disgusting details of the interior arrangements of the "schools" at Mount Joy, visited by Governor Patterson on March 8, show that the 'school syndicate" have made a good speculation in the orphan farming business, while the orphans have fared similarly to the children in charge of Mr Squeers About 250 boys and girls are incarcerated in the place at Mount Joy The domitories were found to be cramped, foul and almost air tight The bed linen was washed by the orphans, when washed at all The clothing of the children was filthy, ragged, and infested with vermin The managers, evidently familiar with Oliver Twist, "abated not one rag in Dodger's coat" In the so called lavatory the bath tub was an old pickle barrel Those of the large boys who cared to perform ablutions with such uninviting accessories crowded into the "bath tub" two or three at a time, to the exclusion of the smaller boys

The medical department of this establishment was presided over by the "school greaser" Cutaneous diseases and sore eyes were common, and twenty or more of the boys were constantly under the care of the juvenile medical officer, an over grown lad, who, with a brush, "painted his patients with three kinds of salve—one for sore heads, a second for body sores, and a third for what he called 'the each'" The supply of clean towels was limited to *one* a day for *forty* boys, and the girls were no better supplied The orphans did most of their own washing, ironing and baking The "play room," for use on cold and rainy days, was "a foul dungeon of a boiler room, with mouldy walls and damp, dirty floors, where the light of day never penetrated" We have been unable to learn anything as to the death rate in this monstrously mismanaged institution, and it is entirely probable that any such information would be grudgingly furnished, if at all, by the managers Nor are there any facts before us which show what becomes of these children when they are old enough to be emancipated from these schools for criminals—for such they must be We do not know what subjects are taught in these schools, but a list of what is not taught might be easily given Uncleanliness of body is inconsistent with bodily health or moral cleanliness It would be no matter for surprise should the majority of these children become criminals, but it is to be hoped that every effort will be made to correct the present abuses and repair the damage already done

SOCIETY PROCEEDINGS

CHICAGO GYNÆCOLOGICAL SOCIETY

LXIII Meeting, Friday Evening, Feb 19, 1886

THE PRESIDENT, DANIEL T NELSON, M D,
IN THE CHAIR

W W JAGGARD, M D, EDITOR

DR A REEVES JACKSON, opened the adjourned discussion of the treatment of pelvic abscess by reading a paper entitled

LAPAROTOMY FOR PELVIC ABSCESS

Owing to Dr Jackson's absence, the paper was read by the Secretary

At the December meeting of this Society, a discussion arose upon the subject of pelvic abscess and its treatment It was based upon the report of a case by Dr H T Byford, which had been treated by favoring discharge of the pus by way of the rectum, and the placing within the abscess cavity a portion of sulphate of copper to promote granulation The discussion seemed unfinished, and was withal of so interesting a character, that I have thought well to reopen it by the relation of the following case Whether the operation performed in the treatment of the case should be termed a laparotomy will depend upon what signficance we attach to the term Upon this point opinions will doubtless differ

If we understand by the world laparotomy, the opening of the abdominal cavity in its largest sense, the term is here correctly used, but if, on the other hand, we mean the opening of the abdomen for the relief of *an encysted intraperitoneal abscess non adherent to the abdominal wall*, the term would not be properly applicable, for here there was complete adhesion, and, possibly, in the course of time the abscess might have pointed and opened in that direction, although I do not believe that such result would have occurred Without active interference I think the disease would have resulted in death from pyæmia in a very few days

On March 9, 1885, I visited Anna N , in consultation with Dr Louis Braun, of this city She was 24 years old, had been married six years, and had one child 18 months old On February 1—five and a half weeks prior to my visit—she had miscarried, producing a fœtus four months old A few days after that event, Dr Braun found the patient suffering from symptoms of pelvic inflammation, which had since continued, with varying severity He informed me that the pelvic swelling, which he detected on examination, appeared to involve all the periuterine structures, but to a greater extent on the right side, that during the past few days, however, it had seemed greater on the left side From the onset of the attack the pulse had been rapid, and the temperature elevated—the former ranging from 110 to 130, and the latter being persistently over 102° F , reaching on one occasion, 104° F Pain had been severe, but controllable by morphia The appetite had failed utterly and the stomach finally rejected all food At the time of my visit, the patient was pale, extremely emaciated, and her visage showed marks of prolonged suffering

On examination, I found on the left side of and behind the uterus a swelling as large as a medium-sized orange, with rather indistinct outlines Its lower portion was in a plane with, or somewhat below, the *os uteri*, and bimanually its upper margin could be felt extending above the fundus, which was pushed strongly to the right Both uterus and tumor were immovable The latter had a slightly elastic feeling in some places, although I was unable to detect any certain fluctuation through the vagina, rectum or hypogastrium Through the posterior vaginal wall, at a point about an inch above the lower portion of the swelling, I fancied I received a sensation of bogginess, and this, taken in connection with the history of the case, gave me the belief that pus was present Accordingly, I thrust a curved trocar and canula into the swelling by way of the vagina to the depth of about two inches, with no other result than the emission of a few drops of blood It was then concluded that the patient should have prolonged hot water vaginal douches daily, rectal feeding, and appropriate anodyne and tonic medicines

On April 18, five weeks later, I saw the patient again, with Dr Braun, who reported that after my former visit the symptoms had all become gradually ameliorated, the stomach resumed its functions, pain subsided, pulse and temperature became normal No menstrual or other discharge had appeared This improved condition had continued until two days before, when without apparent cause, the patient had a chill, followed by rapid pulse, high temperature, pelvic pain and irritability of the bladder

Under anæsthesia I examined the abdominal and pelvic organs The pelvic swelling had undergone no marked change, except that it seemed to have increased in an upward direction, extending now to a point about an inch above the *symphysis pubis* At this place I thought I detected obscure fluctuation The swelling as felt *per vaginam* was hard at every accessible point All operative measures were declined by the patient and her friends, and the treatment advised consisted in the administration of morphia and quinine, and peptonized milk for diet

April 19, the patient was much worse The pelvic pain was controlled only by large doses of morphia given hypodermically, and the stomach retained almost nothing The pulse was 130, temperature 102° F It was decided that laparotomy should be performed the following day

April 20 There were present as assistants Drs Steele, Braun, Sterl, Dickerson and Mascheck A spray of carbolized water had been kept playing in the room for several hours The patient was etherized, and the bladder emptied by catheter She was the thinnest person I ever saw placed upon an operating table Immediately before the taking of ether her pulse was 124, temperature, 103° F The hair of the pubis was shaven off, and the skin of the abdomen washed with soap and carbolized water An incision three inches long, ending below at the upper portion of the *mons veneris*, was made in the middle line of the hypogastrium Deepening the cut, I came upon the peritoneum, which, however, could not be separated from the parts beneath Proceeding inward through dense structures the knife suddenly entered an abscess cavity, which at once gave exit to a stream of pus to the amount of two or three ounces Passing my finger through the opening, I found that the cavity extended downward, behind and to the left of the uterus, about three inches The abscess walls proper could not be accurately defined The inflammatory processes had matted together the upper part of the uterus, the left broad ligament, tube and ovary The cavity was washed out, and a rubber drainage tube passed to the lower end, the outer portion of the tube being stitched to the edge of the wound at its lower extremity The remainder of the wound was closed with sutures, and dressed in the usual manner

The night following the operation the patient slept fairly without an opiate

When I saw her the next day she had taken milk and lime water with relish, her pulse was 108, and temperature 100 1-5° F In brief, the relief of the symptoms was immediate, and the recovery uninterrupted Pus continued to discharge for more than six weeks in constantly diminishing quantity The tube was then removed Menstruation appeared July 20, and has been regular since I examined the patient September 25 The uterus was still in a position of right lateroversion, but movable in a slight degree The parts about the left broad ligament were thickened, and somewhat tender An irregularly shaped mass occupied Douglas's space, and extended upward and to the left The patient had gained greatly in weight, was ruddy, and doing her own housework

In a letter dated December 29, she states, "I have no pain, and feel better than I have for four or five years"

Dr Jackson appended the following note from Mr Lawson Tait

7 The Crescent, Birmingham, Jan 4, 1886

My Dear Sir I have performed now thirty two operations for pelvic abscess, in every one of which a cure has resulted Yours very truly,

Lawson Tait

Dr Christian Fenger said Before entering into the discussion of the paper which has been read here this evening, I wish to remark that I came here under the impression that the entire subject of suppurative, pelvic inflammation was to be dealt with, I now see the subject is limited to the treatment of pelvic abscess by laparotomy The operation performed in Dr Jackson's case I should not call a laparotomy at all, but simply an oncotomy An abscess was opened, and the operation does not differ materially from the opening of a deep seated abscess in any other region of the body, *e g*, in an extremity As I understand the term laparotomy, and I am not aware that it is ever used otherwise, it means that section of the abdominal parietes is followed by an operation, performed within the peritoneal cavity If the wall of an abscess situated in an abdominal organ has become adherent to the visceral surface of the abdominal parietes, the peritoneal cavity is of necessity obliterated to the extent to which adhesions have formed. An incision made over such adhesions does not open the peritoneal cavity, and consequently the operation cannot be spoken of as a laparotomy. In the paper which I published on "Laparotomy for Periuterine Abscess," it was distinctly stated that the only way by which it seemed possible to get at the abscess was by opening the peritoneal cavity. It is also mentioned that omentum and intestines were found between the walls of the abscess and the walls of the abdomen.

Concerning the etiology of pelvic abscess, I should like to call attention to the literature of the subject. Sanger, whose statements regarding etiology I have found to be the most complete, says that one out of nine of all gynecological affections is of gonorrhœic character. He further says that fifty per centum of these are diseases of the uterine appendages, although, of course, any part of the genital tract may be primarily invaded. In the Fallopian tubes he finds that disease most often has its principal focus, where it begins and whence it spreads. He distinguishes six kinds of salpingitis (1), septic, puerperal and non puerperal, (2), tuberculous, (3), syphilitic, (4), actinomycotic, (5), gonorrhœic, (6), a mixed form. The gonorrhœic is the most common form of the disease, and it produces the most severe cases of pelvic inflammation. It has not as yet been proven that the gonococci of Neisser can, of themselves, produce abscesses, but destruction of the surface of the mucous membrane is sufficient, an entrance is thus given to the septic, pus microbes, the *staphylococcus aureus* and *albus* and the *streptococcus pyogenes*, which are probably always present.

The invasion having taken place, we must ask ourselves by what channel does the inflammation travel? Where should we expect finally to find an abscess in case one should form? The Fellows will remember the beautiful experiments of Bitas, Koenig, Schlesinger, experiments which about three years ago I repeated in the dead house of the Cook County Hospital, although the purpose I had in view at that time was a different one. These gentlemen injected, by means of fine canulæ, fluids, such as colored glue, into the periuterine tissues of puerperal and non-puerperal bodies. Koenig found (*a*) that fluids, injected in the region around the *fundus uteri* and uterine portion of the Fallopian tubes, first pass upwards into the iliac fossa to reach the crest of the ilium, then downwards towards Poupart's ligament, and finally into the *pelvis minor* or true pelvis, (*b*) fluids injected into the periuterine tissues, in the neighborhood of the internal os, first fill the extraperitoneal tissue of the *pelvis minor*, then follow the round ligament as far as Poupart's ligament and ascend in a backward direction into the iliac fossa, (*c*) that when the injection is made near the lower portion of the posterior surface of the uterus, the fluid first flows into the *cul-de sac* of Douglas, and thence rises into the iliac fossa. Schlesinger, although in the main agreeing with Koenig, differs with him in the following two points. He says (*a*) when fluid is injected into the neighborhood of the *fundus uteri*, it first passes into the iliac fossa, but thence it does not descend into the true pelvis, as Koenig observed, but it ascends, running up the anterior abdominal wall, (*b*) from the broad ligament the fluid finds its way into the iliac fossa and thence upwards towards the kidney, running in the mesentery of either the ascending or descending colon. Schlesinger further makes the interesting statement that his pericervical injections filled the pericervical tissues, but that they never produced a tumor which could be felt above the *symphysis pubis*. As far as my experience goes, the results of these experiments correspond well with the clinical facts. The puerperal abscesses which I have opened were situated, two over the crest of the ilium, one on Poupart's ligament, and one on the anterior abdominal wall, about three inches above the ligament.

As before mentioned, about three years ago I made similar experiments, the fluid I employed was milk. My object, at the time, was to ascertain the exact relative position of such an artificial exudate, representing an abscess, with regard to one of the broad ligaments. I wanted to see for myself what difficulties I must be prepared to encounter in uniting the walls of a pelvic abscess, after having opened it, to the edges of the abdominal wound. As might have been expected, I found the difficulties of the operation to vary partly with the size of the exudate and partly with the degree of tension of the abdominal parietes. On the whole, the matter seemed simpler to me than I had *a priori* imagined.

Whether in cases of pelvic inflammations and abscesses laparotomy should be done or not, is a question of comparatively recent date, it being but little older than five years. As I have already said in my paper on "Periuterine Abscess," the operation is always to be regarded as a last resort, and should never be thought of in cases in which the abscess can with safety be reached in any other way, which, of course, includes opening it through the rectum. Lawson Tait, of Birmingham, and Martin, of Berlin, were the first who attempted to prevent the terrible contingencies of pelvic inflammations by attacking the disease at its original seat, Lawson Tait removed the suppurating uterine appendages, Martin operated for suppurating periuterine hæmatocele. Tait operated for a suppurating hæmatoma of the right Fallopian tube (peritonitis) in 1878, and he removed both tubes for pyosalpinx and an ovary for abscess in 1885. In 1885 Martin performed laparotomy in three cases of intraperitoneal hæmatoma, *i. e.*, retro-uterine hæmatocele. He opened the peritoneal cavity, incised the sac, and evacuated the blood and pus, he then drained into the vagina, through the pouch of Douglas, and closed the opening he had made into the sac from the peritoneal cavity by sutures. In the discussion following the reading of Martin's paper, Kaltenbach opposed Martin's operation, and pleaded for an extraperitoneal operation, reaching the abscess either from above Poupart's ligament, or, as Hegar recommended, from the ischio-rectal fossa. In 1880, Feldman, of Gottingen, published an operation for double pyosalpinx. In 1882, Baumgartner published a case of hæmatocele in which Martin's operation had been successfully performed. These more or less sporadic operations called the attention of the profession to the subject, and already during the following year, 1883, upwards of fifty or sixty cases were reported in which laparotomy was resorted to for the cure of pelvic inflammations. Aside from the forty-six cases which Lawson Tait published in his book, "Diseases of the Ovaries," he reported seven more. T. Gaillard Thomas reported five cases, Zeiss, Thornton, Baer and Proschownick, each one. In 1884, America was represented by fifteen cases, Stone, 1, Lee, 4, Lusk, 1, Martin, of Chicago, 1, Goodell, 2, Jones, 1, Thomas, 1, Dawson, 1, Polk, 3. In England we have thirty-five cases. Tait, 15, 7 of pelvic abscess, McDonald, 2, Lediard, 1, Chapman, 1, Savage, 9, 8 of pelvic peritonitis and 1 of hæmatocele, Malin, 7. In Germany, twenty-two cases were reported. Martin, 8 of suppurating hæmatocele, Gusserow, 7, in 4 of which the sac was stitched to the abdominal wound, Sanger, 5, Schroder, 1, Quetsch, 1.

It is evident that the operation rapidly gained ground, and that laparotomy has come to occupy a prominent place in the treatment of pelvic inflammations and abscesses. It may be objected that as yet the indications for the operation are not as clearly defined as we might wish them to be, in answer to this, we can only say that the operation is new, and that we must consider the importance of the subject the guaranty of progress in the right direction.

I wish to add a few words about the subject as it is modified in cases in which the periuterine abscess communicates with the rectum or some other part of the intestines. My remarks will have reference to the discussion of my paper on "Chronic Periuterine Abscess," the discussion of to-night being but a continuation of that broken off at our recent meeting for want of time. My paper was read before this Society in May, 1885. I will refer as well to the discussion of Dr. H. T. Byford's paper on "Pelvic Abscess," read here December 18, 1885.

When a communication exists between an abscess and the intestinal tract, evacuation of the pus into the bowel is sometimes followed by spontaneous recovery. As a rule, however, such a condition is extremely dangerous, for the abscess cavity is constantly being infected with septic material from the intestine. Péan, in his "*Diagnostique et Traitement des Tumeurs de l'Abdomen et du Bassin,*" T. 11, p. 155, writes that a periuterine abscess may open into the cæcum, colon or rectum, that if a periuterine abscess opens into the intestine, bladder or uterus, septic infection will not fail to produce its symptoms and may speedily prove fatal. This statement may be a little too broad. Schroder, in his "*Krankheiten der Weiblichen Geschlechtsorgane,*" Leipzig, 1880, says that when the abscess has broken into the gut or bladder we have to deal with a grave condition, as it is difficult or impossible to reach the abscess from the vagina. At that time, in 1880, he had not thought of the practicability of laparotomy in such cases. When the abscess has evacuated itself into the rectum, he considers it less difficult to get access to it, and he advises cutting through the posterior *cul de sac* of the vagina, and dissecting upwards between the uterus and the rectum. Emmet writes that when an abscess opens into the rectum, the case is very much complicated by septic infection through the fæces. The quotations given are sufficient for us to conclude that, when there is communication between a periuterine abscess and the rectum, the patient is in great and constant danger of dying from septic infection, and that, therefore, an operation should be done, if possible, to provide free drainage of the abscess. In discussing my paper, Dr. W. H. Byford said that he was opposed to the line of treatment suggested by me, *i. e.*, laparotomy, that the *sphincter ani* should be dilated or incised, the communication between the abscess cavity and rectum should be dilated with the finger, a steel dilator or the knife, the cavity of the abscess scraped, washed out, and drainage effected *per rectum*.

Aside from the old, now justly abandoned, puncture of a retro-uterine abscess *per rectum*, Dr. Byford's method of attacking such an abscess is to me entirely new. I have nowhere, in the course of my reading, met with a similar suggestion. If the abscess communicate with the intestine at a point beyond the rectum, a rectal operation is of course out of the question. If the opening into the rectum lies three inches or more above the anus, dilatation is hardly practicable. Such openings are often narrow and tortuous, the neighboring organs are immovable, and even if we divide the sphincter and the retrorectal tissues, we are obliged to work in the dark, for it is difficult or impossible to draw such an opening well down into view. The gentlemen present who have extirpated a carcinoma of the rectum, will appreciate the difficulties of operating high up in the gut.

But above all, I must earnestly warn you against adopting Dr. Byford's plan of employing in this region a knife for the purpose of dilating the opening of an abscess. Working here with a knife, we always run the risk of opening the peritoneal cavity, and of dividing large vessels which are bound in the wall of the sac, as I once demonstrated in the walls of an abscess, situated in a broad ligament. The large uterine vessels may be found anywhere, and if wounded, it is next to impossible to ligature them securely.

In a relatively small number of cases the abscess into the rectum near the anus, in these, dilatation may be tried, and it may even effect a cure, as we learn from Dr. H. T. Byford's case. However, we must have heard of more than one case before we can judge of the value of this method of treatment. Being somewhat enthusiastic over his rectal method, Dr. Byford disposes of laparotomy by saying, "The treatment by abdominal section cannot for a moment be entertained, for at least two reasons," of which the first one is that it is necessarily followed by a recto-abdominal fistula, which is incapable of being promptly cured, and is apt to become an unfailing source of systemic infection. Of the numerous examples we have, I need but mention the perityphlitic abscesses to show that an intestino-abdominal fistula does not contraindicate the evacuation of the abscess. We operate to save life, whatever may become of the fistula afterwards, besides, these fistulæ do frequently close In the third case referred to in my paper, it closed in two months The closure of a cœcal fistula is a common occurrence The explanation is not far to seek Whenever an abscess breaks into the gut, the condition of the abscess necessitates such an outlet for the pus When the abscess is drained through a counter opening in the abdominal wall or the vagina, and thus transformed into a fistula, the necessity for emptying its contents into the bowel no longer exists, the opening has become useless, and it gradually contracts A fistula in itself is no source of infection We never hear, for example, of a primary local tuberculosis originating in a fistulous tract An anal fistula, when tuberculous, is always preceded by a local tuberculosis

Dr Byford, further on, criticises my cases in particular, remarking that to operate as does Lawson Tait, before the abscess has discharged, and then treat antiseptically, is an entirely different matter All I have to say to this is, that the doctor has entirely misunderstood Lawson Tait A letter I had the pleasure of receiving from Mr Tait one month after I had published my cases, begins, "I have just read your extremely interesting articles in the *Annals of Surgery*" I shall now pass the letter around to the Fellows of the Society In his second letter to me, Mr Tait says "Concerning your operations for pelvic abscess, I quite agree with you Opening the abdomen is a very much more satisfactory way of dealing with these cases than any other" Dr H T Byford's further remarks on my cases I shall pass by in silence, as I do not think their discussion is in order before the Chicago Gynæcological Society

Dr **W W Jaggard** begged permission to submit an extract of a letter from Dr Paul F Mundé, received about the 15th of February Dr Mundé's large experience in the treatment of pelvic abscess was well known to the Fellows of the Society Dr Mundé writes "I do not agree with Dr Byford's rectal treatment, as a rule, and certainly have not in my quite extensive experience found true laparotomy required to evacuate and drain a pelvic abscess I mean opening the peritoneal cavity

"Neither has my experience been that of Dr Dudley, who says that the mortality from abscess opening into the rectum, is great I have seen only one case that I thought must die, in which there was a spontaneous rectal perforation"

Dr **Henry T Byford** A few years ago Sir James Y Simpson invented the operation of division of the cervix for uterine flexures Almost all gynecologists began performing it, and in a short time had done more harm than good with it Only a few years since Dr T A Emmet invented the operation of trachelorrhaphy While justly maintaining that it is an exceedingly valuable operation in proper cases, he has recently stated that it may have done more harm than good A short time ago, Lawson Tait invented a method of treating pelvic abscess by laparotomy, and surgeons are resorting to it with a certain degree of success The method is gaining favor, and bids fair to be employed with disastrous frequency, and possibly do more harm than good

In endeavoring to fix the limits of the usefulness of laparotomy for pelvic abscess, we must go beyond the recorded experience of the laparotomists, for the records are not yet all in I understand that Tait opens the abdominal cavity only in those cases which cannot be reached from below

Dr **Fenger** remarked, parenthetically He (Tait) does not operate through the rectum He performs laparotomy when he cannot open through the vagina

Dr **Byford**, continuing Then we may say that abscesses like the one reported (which point above) should be opened by a simple incision, without entering the abdominal cavity, and those which point in the vagina should be opened and treated through the vagina Now the question is, should those which point in the rectum be opened and treated through the rectum? What I claim is, that the procedure has not been thoroughly tested by the profession As has already been stated in this Society by Dr Wm H Byford, we can, by thoroughly stretching the sphincter of the anus, get into almost any abscess which is truly pelvic in its nature, and points, or opens, in the lower four or five inches of the rectum We can dilate the opening, and then enlarge it with the fingers, without the use of any cutting instruments, against which objection has just been made The danger of hæmorrhage from the wounding of blood vessels is certainly very much less than the dangers in operating by laparotomy There must be danger connected with any operation, but in the one I am speaking of it is reduced to the minimum The entrance of fæces is of minor importance, for in the presence of perfect drainage and antiseptic irrigations, they do not remain in the cavity, and do not prevent it from filling in with granulations from the top and sides, and contracting and healing Therefore dilatation *per rectum* should be first tried, and if any cases, after trial, cannot be thus successfully treated, laparotomy, or some other substitute, should be considered Dr Fenger quotes, and then criticises, my arguments against laparotomy, without mentioning that I was only referring to abscesses that could be reached through the rectum With regard to recto abdominal fistula, I must still maintain that the abscess will close up and get well more readily with one opening into the rectum, properly made or enlarged, than if such a fistula exist in which the rectal outlet has not been enlarged Gases and fæces will almost invariably pass through and keep the abdominal end of the fistula open, and will lodge in septic pockets, or sinuses, resulting from the inadequacy of the opening at the rectal end If we close such a fistula above, we have the unfavorable conditions of the original abscess, and must still practice dilatation per rectum Martin's method of instituting perfect drainage through the vagina, and then closing the abdominal opening, would undoubtedly be sound in principle, were it not that an operation through the vagina should take precedence when practicable, and when *not*, a single opening from above must be regarded as fulfilling the requirements, as is proved by the experience of Tait and others Hence Martin's method must eventually be relegated to the exceptional procedures

I do not wish the Society to understand that I do not believe in laparotomy for pelvic abscess, but that, being popular and new, it is apt to be resorted to unnecessarily and unjustifiably The remarkable success of Tait should not be allowed to mislead us His mastery of *technique* and fertility of resource in abdominal surgery, justifies him in assuming risks which others may not

Dr Edmund Andrews It seems to me that the usefulness of the operation in proper cases is reasonably certain, but that we must be careful not to incur the risks of laparotomy when safer methods are available It will broaden our views somewhat, if we recollect that an abscess in the cellular tissue about the uterus does not differ materially in nature, principles of treatment, nor results, from abscesses in the cellular tissue in other parts of the pelvis and abdomen One set of laws governs them all, both in pathology and treatment A point to be remembered is, that many cases recover spontaneously in early stages, contrary to the statements of some eminent men A professional gynecologist or surgeon, whose patients are attracted to him from long distances on account of his reputation, gets a class of cases, because of their long standing and obstinate character He has to combat the same tendency to error of judgment in one respect which besets the mind of a pathologist, whose conclusions are too exclusively drawn from the dead house, that is to say, neither of them sees the numerous cases which recover under ordinary treatment, and therefore do not come before them Recoveries from abscesses in the cellular tissue in all parts of the abdomen and pelvis are common, though they are apt to be very slow

I recall two cases, attended by well known physicians in this city, which recovered from such absceses after suffering about a year These abscesses discharged through the rectum I have, perhaps, been somewhat slow in the treatment of these cases For example, a retrouterine abscess was brought to me from a distant state It periodically discharged into the rectum above the reach of the finger The patient arrived in Chicago in fair general health Directly after her arrival, the discharges grew smaller in quantity, with longer intervals of time between, and she continued to progress in that way Improving constantly in strength and activity, she began to make excursions and long visits to friends in neighboring States, and, in short, enjoyed life so thoroughly that I deemed a laparotomy not justifiable so long as she progressed so well towards recovery without it I presume she got tired of my dilatory plan At any rate, after some months of improvement she ceased to report herself for periodic examination, and I lost sight of the case I have a case now on hand in a more debilitated condition She is confined to her bed the greater part of the time I expected to operate many weeks ago, but soon after I took charge of the case she showed signs of improvement, which led me to postpone the laparotomy to see what would occur The discharges, which were from a point high up in the rectum, grew less in quantity and further apart in time The temperature went down to the normal standard and remained there, the tumor about the uterus diminished in size, and nearly two months have now elapsed since the last small discharge of pus The patient's vigor is slowly returning Under such conditions it is not certain that any pus cavity remains I deem it my duty to wait until the presence of such a collection of pus is reasonably certain before subjecting the patient to the perils of laparotomy Not long ago I had the opportunity to make a post-mortem examination in a case of circumuterine abscess The abscess had formed several years ago, after a difficult parturition I saw the patient in consultation a few times during the last weeks of life The pus was discharged, partly by the rectum and partly through a fistula midway between the *symphysis pubis* and the umbilicus She had been subjected twice to some surgical operation, whose exact nature I did not learn The operations were not laparotomies Having received no benefit, the patient was determined that no more surgery should be tried on her

After some weeks she died of asthenia, and I was allowed a limited autopsy The fistula above the pubes, after passing through the integuments, led downward and to the right, and at a point which seemed to be the right external inguinal ring it entered the inguinal canal and followed the round ligament into the pelvis Here it became more spacious, but exceedingly crooked and complicated, winding irregularly backward until it opened into the upper part of the rectum All the viscera in the vicinity were glued together in a mass by old inflammatory deposits There was no large abscess cavity at any one point, but still there was a flattened pocket some three inches long, and an inch or more in width, lying behind the rectum in the hollow of the sacrum It contained a little pus and fæces This pocket might have been safely opened from below, working up outside the posterior surface of the rectum, had it been possible to ascertain its existence I do not see how it could have been reached by laparotomy The anterior fistula might have been benefited by freely slitting up the inguinal canal I feel compelled to differ with my friend Dr Henry T Byford in one point He suggests very naturally that Tait's operation, performed after the abscess cavity has opened into the rectum, would make a complete intestinal fistula, which it might be impossible to heal This thought is natural, and I confess I would think the same thing myself, had not an extensive observation upon fæcal fistulæ shown me the reverse Experience teaches that an abscess cavity opening into an intestine and filled with putrid pus and fæces, is very reluctant to heal so long as it is not freely drained and disinfected, but if it is widely opened, so as to make and maintain the shortest and straightest possible route from the opening in the cut to the external air, and if it be kept well cleansed and disinfected, fresh granulations will spring up, the orifice will contract and the fistula will heal, provided there is no stricture in the intestine below This fact, or law, is very important, and applies equally to fæcal and urinary fistulæ, as I have verified by an abundant experience A striking case in point occurs to me at this moment An eminent physician on the South Side requested me to take charge of one of his patients, a lady who seemed to have an anomalous hernia, and was sinking under a suppurative discharge from the bowels On examination I found her confined to bed, and rapidly approaching fatal exhaustion There were several evacuations daily of mingled pus and fæces from the rectum The left hip was found prominent over the whole gluteal region The tumor fluctuated on palpation, was resonant on percussion, and gave a succussion on coughing At times it gurgled under pressure I opened it very slowly and carefully, fearing to find an intestine there After passing through the atrophied gluteus maximus, I entered a broad cavity containing neither intestine nor omentum, but filled with pus and fæces This cavity being emptied and washed out, was easily traced up to the sciatic notch, where it entered the pelvis by an orifice of moderate size I now ripped the cavity open for nearly its whole length and kept it cleansed Vigorous granulations sprang up at once and the sac healed up rapidly and permanently The patient seemed relieved of a great depressing influence, and rebounded at once toward health She became plump and rosy, and rapidly regained her full strength

Dr F E Waxham presented for examination a

FEEDING BOTTLE FOR USE IN CASES OF INTUBATION OF THE LARYNX

The feeding bottle consists of an ordinary nursing flask, with a rubber cork, with a small vent through which a tube passes to the bottom of the bottle To this tube is attached another leading to the bulb of a Davidson's syringe, and this in turn is attached to a small sized œsophageal tube In using this apparatus the gag is placed between the jaws, the tube introduced into the œsophagus and the contents of the bottle quickly introduced by means of the bulb

Many patients, especially young infants, do not take sufficient nourishment after intubation has been performed, on account of the coughing produced by the trickling of the liquid into the trachea This apparatus obviates this difficulty

Yellow Fever—A Brazilian Pasteur —Treatment and Prophylaxis of Yellow Fever by Inoculation of the Attenuated "Cryptococus Xanthogenicus"—Beri-beri, its Etiology and Genesis—Dr Moncorvo and the "Polyclinica Geral"—Aneurism of the Subclavian

The medical world will soon wake up to the fact that scientific research is not confined to the great European centres, and that a "Koch" or a "Pasteur" is quite as likely to turn up in the new as the old world Brazil is already putting in her claim for a share of attention Dr Domingos José Freire, the results of whose studies on yellow fever have been going the rounds of the medical journals, has been called the Brazilian Pasteur, and well deserves the title His recent work on the "Doctrine Microbiénne de la Fièvre Jaune," is a monument of honest, painstaking labor in a very difficult field, extending over a period of several years, it is a work of 630 pages, written in the simple, direct style of your true scientist, and accompanied by elaborately executed plates, illustrating the various steps of the work which led to the discovery of the "Cryptococus Xanthogenicus," with carefully prepared tables of the hospital and laboratory experiments, by which he established a causal relation between his new found microbe and the yellow fever

In a recent pamphlet he gives the net results of his 6000 inoculations of the pure culture, carefully recorded and kept track of, when practicable So far, none of them have died of yellow fever, while more than four hundred persons *not inoculated*, inhabiting the same neighborhood, have succumbed to the disease These are ugly figures for the anti microbists As a matter of course, he meets with a great deal of adverse criticism and opposition among his colleagues in Rio It is the old story, "A prophet is not without honor save in his own country" People who live beyond the radius of personal prejudice, however, recognize the significance of these facts The comparative death rate from yellow fever for the last three years is 1883, 1336, 1884, 618, 1885, 374 The part of the total mortality of 1885 credited to yellow fever is 3 6 per cent , against 16 2 per cent in some of the bad years

In a recent communication from Dr Freire he claims, in his own words, that "La *prophylaxie est un fait deja acquis*, je ne hésite pas à l'affirmer et ne cesserai de le confirmer de plus en plus Quant à la *thérapeutique*, les observations suivante nous inspirent les plus belles et les plus flatteuses espérances " Following this are the details of four cases of undoubted yellow fever, treated by him, after Pasteur's method, with the attenuated yellow fever microbe, by injecting a gramme of the liquid culture into the region of the deltoid He also reports three cases treated in the same way, in his hospital, by the late Charles Browne—seven cases in all, with seven recoveries! In each case there was a marked amelioration within twenty four hours In one case only was a second injection necessary

The present season bids fair to afford the learned Professor ample opportunities for pursuing his studies The intense heat, scarcity of water, and general bad sanitary condition of Rio favor the development of an epidemic The daily increasing death rate from yellow fever is already beginning to give serious concern Dr Freire's report of this season's work in the fever districts will be looked for with unusual interest

Beri beri is now, and has been for a year or two, ravaging the whole coast line of Brazil lying within the tropics, and attracts more attention than even yellow fever, its per centage of deaths reaches in some localities the appalling figure of 74 50 per cent of all attacked, and the total mortality of the coast is *treble that of yellow fever* The beri beri, or *barbiers of Brazil*, differs widely from the disease bear ing the same name in India, and described by Morehead, Aiken, and others, yet it preserves a significant number of the leading features to establish its identity Of the three types—the paralytic, the œdematous, and the mixed—about 67 per cent are of the paralytic I saw a great many cases along the coast last July, among them some of the so called "galloping" cases, where the patient succumbs in a few hours The symptoms are, at first glance, those of a myelitis A great many papers have been written on the disease, the most valuable and complete being that of Dr J F de Silva Lima, of Bahia, giving a full history of the disease from its first appearance in Brazil Unfortunately, this work was written several years ago, and does not embrace the later observations Dr J B de Lacerda, the author of the permanganate of potash treatment for snake bite, and who, by the way, is one of the ablest microscopists and most indefatigable investigators in the Empire, has published two works on beri beri, and claims to have identified it with the "*horse pest*" of the island of Marajo, and to have discovered the "microphyto beriberigeno" Whether Dr Lacerda succeeds in making his microphyte stick or not, he has written a very valuable book and thrown a good deal of light upon an important subject

The profession is indebted to Dr Moncorvo, of the Rio Polyclinic, for several valuable monographs on diseases of children "The Frequency of Dilatation of the Stomach in Children," "Temperature of the Abdominal in Enteritis of Children," "Whooping Cough, and the use of Muriate of Cocaine in its Treatment," "Resorcin in the Treatment of Whooping Cough," etc

Prof Saboia, of the Imperial Academy of Medicine, recently operated upon an aneurism of the right subclavian, by electro puncture, after the manner of Prof Ciniselli Fourteen elements were used, and after thirty five minutes the tumor became hard and ceased to pulsate

It will be seen by the foregoing that medicine is alive in Brazil, and likely to be heard from in the future H M L

DOMESTIC CORRESPONDENCE

LETTER FROM NEW YORK

(FROM OUR OWN CORRESPONDENT)

Dr Flint—The Discussion on Glycosuria—Jambol and Matzoon in Diabetes—Cremation not a Necessary Sanitary Measure—The Meeting of the Fifth District Branch—Dr Charles H Phelps—Dr Ezekiel Wade—Curious Hallucination

At the meeting of the Academy of Medicine held March 18, when the death of ex President Austin Flint was announced, the President, Dr A Jacobi, stated that he would claim for himself the privilege of pronouncing before the Academy the eulogy on his illustrious predecessor in the office Dr Stephen Smith was appointed to prepare a memoir of the late Dr Alfred C Post

The subject of the evening's discussion, which was introduced by the Section on Theory and Practice of Medicine, was Glycosuria The first question propounded was, *The Significance of Small Quantities of Sugar in the Urine*, and it cannot be said that a great deal of light was thrown upon the subject by the speakers participating in the debate, although considerable information was elicited in regard to the difficulty of detecting small amounts of sugar and the best methods for accomplishing this Unfortunately, both the gentlemen who were expected to read papers upon this subject, Dr E C Seguin and Dr L Weber, were unable to be present, and the discussion was entirely an extemporaneous one Dr T A McBride said that while sugar was not infrequently found in the urine in connection with phthisis, pleurisy, cardiac disease, cerebral hæmorrhage, certain of the psychoses, and other grave forms of disease, it was recognized at the present day that in moderate amount sugar might itself be the cause of various nervous troubles, such as insomnia, so called neurasthenia, paræsthesia certain pareses and even temporary hemiplegia The quantity of sugar present in the urine in these cases varies from a trace to 2½ per cent, though as large a proportion as the latter figure was rare On the whole, he felt obliged to confess that he was now somewhat at a loss to say what was really diabetes and what was not

Dr George B Fowler called attention to the fact that sugar was often to be found in the urine of those taking sweets freely, particularly on an empty stomach, and said that patients in whom there was slight glycosuria, with more or less defective digestion, would frequently recover very quickly under a properly regulated diet

Dr Wm H Draper remarked that he had ceased to attach much importance to the occasional occurrence of very small quantities of sugar in the urine, for the reason explained by Dr Fowler He found it very often, particularly in the lithæmic state, in which there were seen the evidences of suboxidation When crystalline uric acid and the urates in large amount were present in the urine, sugar was very apt to be found also All were to be attributed alike, he thought, to defective metabolism, and the treatment which rendered the urine normal in other respects, would also remove the sugar from it As Dr McBride had remarked, it was difficult to say where diabetes really commenced Sugar was not infrequently found in the urine of patients passing not only imperfectly assimilated hydrocarbons, but also nitrogenous food, and therefore sugar was often to be regarded simply as an indication of dyspepsia He did not think one could distinguish any difference in the cases of nervous disturbance in connection with lithæmia, whether sugar was formed in the urine or not Bence Jones had long ago remarked that the "sour disease," or gout, was very closely allied to the "sweet disease," or diabetes mellitus, and had pointed out the important fact that gout and diabetes very frequently existed in the same families, and even in the same individual

The President, Dr A Jacobi, said that in a great many persons, at times sugar was found in the urine in small quantities which could be detected by the ordinary tests When he was a student he had been taught that diabetes was a very rare disease, and was always fatal It was true, indeed, that the cases in which the specific gravity ranges from 1040 to 1060 were rare, but cases in which it ranges from 1017 to 1035 were very frequent, and they were by no means always of a mild character Still, quite a large number of such patients lived a long time, and some got entirely well A considerable proportion of these cases are in gouty individuals beyond middle life When their general heath was good, very little sugar was to be found in the urine, but when they began to fatten up and took little exercise, the quantity might be sufficient to produce pruritus vulvæ in the case of females When such patients contracted other diseases, however, and especially pulmonary affections, they were in the greatest possible danger, and, as a rule, they would not survive an attack of pneumonia Having mentioned the case of four brothers, all of whom were or had been the subjects of diabetes, he remarked that this history showed that in a large number of cases the presence of sugar in the urine indicated defective assimilation If this condition was not appropriately treated, it might result in persistent diabetes and perhaps finally terminate in pulmonary disease He would say, there fore, that sugar in small quantities did not signify much, as long as a good general state of health was maintained, but it might be the source of great danger when other disease set in

In the course of the discussion of the second topic, which was the *Treatment of Diabetes*, Dr Cauldwell related his experience with the recently discovered so called specific, jambol He had prescribed it in four well marked cases of the disease, in each of which the patient was passing more than 100 ounces of urine, while in all the specific gravity of the urine was above 1035 All the patients were treated alike, and, in addition to the use of the drug, was kept on anti diabetic diet, with a moderate allowance of toasted bread Five grains of the powdered jambol seed were given three times a day In the first case the effect was apparently quite remarkable Within two months the patient gained twelve pounds in weight, and the sugar disappeared entirely from the urine For a month past it has remained absent In the second case, on the other hand, no effect whatever was produced by the remedy, as far as could be perceived, but in the third and fourth cases the results were beneficial In one the daily quantity af urine passed was reduced to eighty two ounces, with a specific gravity of 1030, and in the other to fifty ounces, with a specific gravity of 1028, while in the latter case the patient had gained ten pounds in weight In addition, Dr Cauldwell referred to two cases which had been under the care of Drs Keyes and Alexander, in one of which the improvement had been very satisfactory, while in the other there was no improvement whatever In four cases out of six, therefore, the use of jambol had been followed by improvement, and in two it had proved a failure

Dr Draper remarked that, excluding the dietetic treatment, it might be truly said that the treatment of diabetes was as purely empirical as our knowledge of its pathology was speculative There was no trustworthy evidence that drugs alone, without the more or less complete restriction of saccharine and starchy food, were of any service, and while medicinal agents were undeniably useful as adjuvants, his experience led him to believe more and more that the dietetic and hygienic management constituted the essential factor in the successful treatment of this affection The three medicines which had proved of the most service in his hands were codeia, sulphide of calcium, and the alkaline carbonates His attention had first been called to Dr N C Husted, who himself recovered from diabetes under the use of this drug, which he originally took for the relief of furuncles It was followed with good results in a considerable number of cases, especially in gouty subjects, and he believed that it enabled the diabetic to indulge in a greater variety of food than he could otherwise do The alkaline carbonates he had also proved very valuable, and, believing, as he did, that both gout and diabetes are not infrequently due to defective metabolism, he thought that it was a rational treatment to stimulate oxidation

Dr Dadirrian, who has practiced for some time in Constantinople, spoke of the good effects of matzoon, or fermented milk-food, in which the sugar is converted into lactic acid, and which is used largely throughout the East, and Dr Baruch strongly advocated the efficacy of judicious active and passive exercise in diabetes, the amount of exercise being regulated by the strength of the patient

At the last meeting of the New York Society of Medical Jurisprudence and State Medicine, its venerable President, the distinguished surgeon, Dr Frank H Hamilton, read a paper on *Cremation*, in which he took a somewhat different view of the subject from what is entertained by many in the profession at the present day, but one which it would perhaps be well for some enthusiasts to ponder over before committing themselves to such rash and uncalled for measures as have recently been proposed and discussed This conservative paper of Dr Hamilton's was called out by a proposition made by a member of the Society of Medical Jurisprudence at a preceding meeting to ask the Legislature of the State of New York to enact a law making compulsory the cremation of persons who have died of certain infectious diseases, and of those who are buried at the public expense, and it was entitled "*Cremation of Human Bodies Not a Necessary Sanitary Measure*" He said that he could not approve of the proposed legislation, or of any legislation making it obligatory that the body of any person who has died of any disease, or under any circumstances whatever, shall be cremated, and for the following reasons

First The danger to health and life from the present mode of burial, when the inhumation has been properly made, has, by the advocates of cremation, been greatly over-estimated, if, indeed, it can be said to exist at all

Second Cremation removes effectually one of the most important means of detecting certain crimes

Third The general sentiment of the community in which we live is opposed to cremation, and, in view of the facts above stated, it would be unnecessary, unwise, and unjust to impose cremation by legal enactments

The first of these, he thought, was perhaps the only one at present requiring extended discussion, and to this he especially devoted his attention In speaking of the comparative innocuousness of the emanations from abattoirs, he said The mortuary and general sanitary statistics of Chicago will probably not show that it is any more unhealthy to day than it was before it became the slaughter house of the world, nor has it been said that Cincinnati has suffered in its sanitary reputation by the immense growth of its industry in the slaughter and packing of hogs for home and foreign markets He did not wish to be misunderstood, however He did not intend to say that decaying animal matter does not give out noxious gases, and when these are present in the atmosphere in certain quantities and under certain circumstances that they do not cause sickness and death, but only that, in the light of the observations which he had made in reference to the emanations from decaying human and other animal bodies, the dangers from these sources have, in the popular mind, been greatly exaggerated

In treating of the immunity from infection of those constantly working in dissecting rooms, he quoted the opinion of Duchatelet, after a thorough investigation of the subject (an opinion that was concurred in by Lallemand, Dessault, Dubois, Dupuytren, Boyer, Andral, Lawrence, of London, and Warren, of Boston), that it was "an error to suppose that the air of a neighborhood is ever contaminated—so as to induce disease—by the emanations from dissecting rooms, or that the students ever suffer from breathing the impure air of those places" After referring to the various dissecting-rooms of this city he said "I am informed, I think authoritatively, that, according to some recent experiments, the air of the autopsy rooms, and of the other rooms attached to the dead-house (at Bellevue) contained fewer septic germs than the most favored ward in Bellevue Hospital, namely, the Osborne ward, which is a new, outlying, one story brick pavilion, and which is considered a model of sanitary construction, arrangement and police"

In considering to what extent health and life are endangered by emanations from animal bodies buried beneath the surface of the earth, he stated that chemistry and experience have alike demonstrated that the escaping gases, and the fluid or solid organic matters which sometimes find exit with them, rapidly undergo changes by entering into new combinations when brought into contact with the earth This was illustrated in the familiar experience with the so called "earth closet," and was to the scientist a well known fact If many bodies were deposited at the same time in a great vault, or in superficial trenches, it would be easy to understand how the gases and organic matter might, for a time, penetrate the soil unchanged, and in a sufficient amount to render the surrounding atmosphere and the adjacent water unwholesome, although after the great battles of modern times, where many thousands have been thus buried in a single day, no accounts have reached us of sickness or of pestilence thereby induced In the case, however, of our civic and rural burial grounds, within which bodies are deposited one by one, at considerable intervals of time and at great depth, it would seem impossible, in the light of the accumulated testimony now presented, that any harm should come to the living

Having remarked that nearly all of the testimony adduced by the cremationists, if not all of it, was drawn from the assumed noxious emanations from certain burial grounds in Europe or Asia, and thus placed beyond the reach of critical investigation, he said it was, in fact, a just ground of complaint that the American advocates of cremation as a hygienic measure do not draw their illustration from examples supplied by our own country In order that his position might be fairly understood, he thought it well to say that he was defending the mode of burial usually practiced in this country, namely, from four to six feet below the surface of the earth, as in itself a complete sanitary measure, and as rendering cremation unnecessary New Orleans, and all other cities where the dead cannot be buried to a sufficient depth beneath the surface, might do well to consider the alternative of cremation, but this admission, he thought, supplied no argument against inhumation where it can be properly done Any who would feel interested in following out Dr Hamilton's argument in full will find the paper in the April number of *Gaillard's Medical Journal*

A successful special meeting, for scientific purposes, of the Fifth District Branch of the New York State Medical Association, was held at Yonkers, on the Hudson, on March 23 The gathering took place in the Common Council Chamber, which is situated in the ancient Phillipse manor house, one of the oldest and finest colonial buildings in the country, the bicentennial of which was celebrated with elaborate and appropriate ceremonies in October, 1882 The programme of scientific papers, which has been published in THE JOURNAL, was carried out, and several memoirs of deceased Fellows were read Much interest was shown in the proceedings, and it was decided to have another special meeting of the Branch in June next This will be held at Kingston, Ulster County, and it is probable that a delightful excursion to the neighboring Catskills will be arranged in connection with it

The Governor of the State has made a very satisfactory appointment in nominating as Health Officer of the Port Dr Charles H Phelps, who has already acceptably filled a number of medical positions of importance, and is at present one of the attending surgeons to Bellevue Hospital, of the Medical Board of which, as well as of the Board of Police Surgeons, he is President He also has a large practice, and is much liked personally One of the three Quarantine Commissioners whom Governor Hill nominated at the same time is also a physician, Dr John H Douglas, who has become widely known all over the country by his connection with the case of General Grant

Dr Ezekiel Mulford Wade, who died at his residence in the town of Watervliet, New York, in the early part of March, was a grandson of Edward Wade, a Revolutionary patriot who took part in the Battle of Bunker Hill His father, James Wade, M D, was quite a noted physician, his practice extending into Albany, Schenectady, and Saratoga counties, and his reputation is said to have been established during a notable epidemic of so called typho pneumonia, in which nearly all other physicians in the region lost almost every patient within twenty-four hours after the bleeding then resorted to as a routine practice at the beginning of the treatment By avoiding bleeding, and by the use of supporting measures, he saved nearly all his cases

The other evening a woman apparently about 45 years of age presented herself at police headquarters and asked for protection, who was suffering under a somewhat unusual hallucination She stated that she was followed by relatives who wanted to administer to her hypodermic injections of morphia, and though she had thus far been able to baffle their efforts, she feared that she would not be able to do so any longer P B P

"THE FUTURE OF THE AMERICAN MEDICAL ASSOCIATION"

To the Editor of the Journal

Dear Sir The Philadelphia *Medical News* of February 27, under the above caption, published an article from the *Nashville Medical and Surgical Journal*, of February 1886, which reads as follows

"The meeting of the American Medical Association at St Louis, Mo in May next, will be a most important one Surely, every physician who holds the honor of his profession dear, should either go himself, or interest himself in sending such representatives as are honorable and pure, and free from all selfish motives for self-advancement and preferment, and fully alive to the important issues that will be discussed at this meeting The topic of the International Medical Congress will be the absorbing question for discussion *Of late years this Association has appeared to degenerate into a body merely medico political*, and it is time something should be done to elevate it to a proper standard and make it what the British Medical Association is to the profession in England, representative and national *Political intrigue and trickery* have too long held sway in this Association, and it is time the profession should see to it, that it be no *longer thus degraded* and be brought back to the place it occupied in its palmiest days From year to year the meetings have become less and less important in a scientific point of view, and it is time every true physician should individually strive to change its downward course If some change is not soon effected, the Association will cease to exist, and the profession will turn its attention to the separate special Associations, which are all now in a flourishing condition We hope, therefore, that all who can, will make an effort to attend the coming meeting"

Surely no intelligent physician can read the above quotation and be at a loss to divine both its origin and animus The deep solicitude manifested for the well being of the Association and the terms of affection are covered by a veil too thin to conceal the venom rankling in the bosoms of disappointed schemers and plotters to overthrow, or disgrace, or humiliate the American Medical Association—an Association dear to the great overwhelming mass of the medical profession, and should be, to every true and honorable physician in this land and country It is written somewhere in the Holy Scriptures, "that a man's (worst) enemies are the men of his own household" It does seem to me that in this unnecessary and unreasonable antagonism to the Association, and I may say tirade of slander, this saying is literally fulfilled It is humiliating to our profession to read such untrue and venomous statements as are contained in the foregoing quotation, and we are wonderstruck that any medical journal, having any pretentions to honorable professional pride and respectability, should reproduce it without denouncing it as a spiteful calumny When did the American Medical Association degenerate into a "body merely medico-political?" And when did "political intrigue and trickery" commence, which the splenic writer affirms have too long held sway in this Association?

The truth of the matter is that, until the last meeting of the Association, we never heard of any such changes, neither a hint of such suspicion Up to that time the Association was held to be a body of honorable men intent only to work for the good of the profession—to elevate the standard of medicine and to maintain the true honor and dignity of medical science But at the meeting in New Orleans it did come about that a few ambitious schemers, (I will not say political intriguers) made their appearance (by proxy) desiring to get control of the Association, and to use it in their own preferment and distinction, to the exclusion of members fully their peers in every essential quality of medical and scientific culture, and because their schemes were resisted and frustrated as selfish and sectional, and the Association held true to its honor and representative national character, these discomfited schemers have resorted to every misrepresentation to injure the Association, and to make the meeting of the International Medical Congress in this country in 1887 a failure Can any fair minded man conceive of any course more despicable on the part of physicians claiming to be honorable and the leaders of medical thought?

Now, in good faith, what was the real offence given by the Association at the meeting in New Orleans? It did not displace any one of the seven the Committee appointed at its meeting in Washington in 1884 It simply added others, enlarged the Committee to make it more representative of the entire medical profession of the United States, in whose name the Association had extended the invitation to the International Medical Congress, and to this Committee thus enlarged, the power was given to revise the work already done, and to perfect and complete every arrangement for the successful meeting of the Congress in Washington City in 1887 Was there "medico political" trickery in the exercise of this clear and undoubted right? Was there anything in it that should have wounded the feelings and given offence to any honest medical worker, unselfishly labor-in which we live is opposed to cremation, and, in view of the facts above stated, it would be unnecessary, unwise, and unjust to impose cremation by legal enactments.

The first of these, he thought, was perhaps the only one at present requiring extended discussion, and to this he especially devoted his attention. In speaking of the comparative innocuousness of the emanations from abattoirs, he said: The mortuary and general sanitary statistics of Chicago will probably not show that it is any more unhealthy to-day than it was before it became the slaughter-house of the world, nor has it been said that Cincinnati has suffered in its sanitary reputation by the immense growth of its industry in the slaughter and packing of hogs for home and foreign markets. He did not wish to be misunderstood, however. He did not intend to say that decaying animal matter does not give out noxious gases, and when these are present in the atmosphere in certain quantities and under certain circumstances that they do not cause sickness and death, but only that, in the light of the observations which he had made in reference to the emanations from decaying human and other animal bodies, the dangers from these sources have, in the popular mind, been greatly exaggerated.

In treating of the immunity from infection of those constantly working in dissecting rooms, he quoted the opinion of Duchatelet, after a thorough investigation of the subject (an opinion that was concurred in by Lallemand, Dessault, Dubois, Dupuytren, Boyer, Andral, Lawrence, of London, and Warren, of Boston), that it was "an error to suppose that the air of a neighborhood is ever contaminated—so as to induce disease—by the emanations from dissecting rooms, or that the students ever suffer from breathing the impure air of those places." After referring to the various dissecting-rooms of this city he said: "I am informed, I think authoritatively, that, according to some recent experiments, the air of the autopsy rooms, and of the other rooms attached to the dead-house (at Bellevue) contained fewer septic germs than the most favored ward in Bellevue Hospital, namely, the Osborne ward, which is a new, outlying, one-story brick pavilion, and which is considered a model of sanitary construction, arrangement and police."

In considering to what extent health and life are endangered by emanations from animal bodies buried beneath the surface of the earth, he stated that chemistry and experience have alike demonstrated that the escaping gases, and the fluid or solid organic matters which sometimes find exit with them, rapidly undergo changes by entering into new combinations when brought into contact with the earth. This was illustrated in the familiar experience with the so-called "earth-closet," and was to the scientist a well-known fact. If many bodies were deposited at the same time in a great vault, or in superficial trenches, it would be easy to understand how the gases and organic matter might, for a time, penetrate the soil unchanged, and in a sufficient amount to render the surrounding atmosphere and the adjacent water unwholesome, although after the great battles of modern times, where many thousands have been thus buried in a single day, no accounts have reached us of sickness or of pestilence thereby induced. In the case, however, of our civic and rural burial grounds, within which bodies are deposited one by one, at considerable intervals of time and at great depth, it would seem impossible, in the light of the accumulated testimony now presented, that any harm should come to the living.

Having remarked that nearly all of the testimony adduced by the cremationists, if not all of it, was drawn from the assumed noxious emanations from certain burial grounds in Europe or Asia, and thus placed beyond the reach of critical investigation, he said it was, in fact, a just ground of complaint that the American advocates of cremation as a hygienic measure do not draw their illustration from examples supplied by our own country. In order that his position might be fairly understood, he thought it well to say that he was defending the mode of burial usually practiced in this country, namely, from four to six feet below the surface of the earth, as in itself a complete sanitary measure, and as rendering cremation unnecessary. New Orleans, and all other cities where the dead cannot be buried to a sufficient depth beneath the surface, might do well to consider the alternative of cremation; but this admission, he thought, supplied no argument against inhumation where it can be properly done. Any who would feel interested in following out Dr. Hamilton's argument in full will find the paper in the April number of *Gaillard's Medical Journal*.

A successful special meeting, for scientific purposes, of the Fifth District Branch of the New York State Medical Association, was held at Yonkers, on the Hudson, on March 23. The gathering took place in the Common Council Chamber, which is situated in the ancient Phillipse manor house, one of the oldest and finest colonial buildings in the country, the bicentennial of which was celebrated with elaborate and appropriate ceremonies in October, 1882. The programme of scientific papers, which has been published in The Journal, was carried out, and several memoirs of deceased Fellows were read. Much interest was shown in the proceedings, and it was decided to have another special meeting of the Branch in June next. This will be held at Kingston, Ulster County, and it is probable that a delightful excursion to the neighboring Catskills will be arranged in connection with it.

The Governor of the State has made a very satisfactory appointment in nominating as Health Officer of the Port Dr. Charles H. Phelps, who has already acceptably filled a number of medical positions of importance, and is at present one of the attending surgeons to Bellevue Hospital, of the Medical Board of which, as well as of the Board of Police Surgeons, he is President. He also has a large practice, and is much liked personally. One of the three Quarantine Commissioners whom Governor Hill nominated at the same time is also a physician, Dr. John H. Douglas, who has become widely known all over the country by his connection with the case of General Grant.

Dr. Ezekiel Mulford Wade, who died at his residence in the town of Watervliet, New York, in the early part of March, was a grandson of Edward Wade, a Revolutionary patriot who took part in the battle of Bunker Hill. His father, James Wade, M.D., was quite a noted physician, his practice extending into Albany, Schenectady, and Saratoga counties, and his reputation is said to have been established during a notable epidemic of so called typho pneumonia, in which nearly all other physicians in the region lost almost every patient within twenty-four hours after the bleeding then resorted to as a routine practice at the beginning of the treatment. By avoiding bleeding, and by the use of supporting measures, he saved nearly all his cases.

The other evening a woman apparently about 45 years of age presented herself at police headquarters and asked for protection, who was suffering under a somewhat unusual hallucination. She stated that she was followed by relatives who wanted to administer to her hypodermic injections of morphia, and though she had thus far been able to baffle their efforts, she feared that she would not be able to do so any longer.

"THE FUTURE OF THE AMERICAN MEDICAL ASSOCIATION."

To the Editor of the Journal.

Dear Sir: The Philadelphia *Medical News* of February 27, under the above caption, published an article from the *Nashville Medical and Surgical Journal*, of February 1886, which reads as follows:

"The meeting of the American Medical Association at St. Louis, Mo., in May next, will be a most important one. Surely, every physician who holds the honor of his profession dear, should either go himself, or interest himself in sending such representatives as are honorable and pure, and free from all selfish motives for self-advancement and preferment, and fully alive to the important issues that will be discussed at this meeting. The topic of the International Medical Congress will be the absorbing question for discussion. *Of late years this Association has appeared to degenerate into a body merely medico political*, and it is time something should be done to elevate it to a proper standard and make it what the British Medical Association is to the profession in England, representative and national. *Political intrigue and trickery* have too long held sway in this Association, and it is time the profession should see to it, that it be no *longer thus degraded*, and be brought back to the place it occupied in its palmiest days. From year to year the meetings have become less and less important in a scientific point of view, and it is time every true physician should individually strive to change its downward course. If some change is not soon effected, the Association will cease to exist, and the profession will turn its attention to the separate special Associations, which are all now in a flourishing condition. We hope, therefore, that all who can, will make an effort to attend the coming meeting."

Surely no intelligent physician can read the above quotation and be at a loss to divine both its origin and animus. The deep solicitude manifested for the well being of the Association and the terms of affection are covered by a veil too thin to conceal the venom rankling in the bosoms of disappointed schemers and plotters to overthrow, or disgrace, or humiliate the American Medical Association—an Association dear to the great overwhelming mass of the medical profession, and should be, to every true and honorable physician in this land and country. It is written somewhere in the Holy Scriptures, "that a man's (worst) enemies are the men of his own household." It does seem to me that in this unnecessary and unreasonable antagonism to the Association, and I may say tirade of slander, this saying is literally fulfilled. It is humiliating to our profession to read such untrue and venomous statements as are contained in the foregoing quotation, and we are wonder-struck that any medical journal, having any pretentions to honorable professional pride and respectability, should reproduce it without denouncing it as a spiteful calumny. When did the American Medical Association degenerate *into* a "*body merely medico-political?*" And when did "political intrigue and trickery" commence, which the splenic writer affirms have too long held sway in this Association?

The truth of the matter is that, until the last meeting of the Association, we never heard of any such changes, neither a hint of such suspicion. Up to that time the Association was held to be a body of honorable men intent only to work for the good of the profession—to elevate the standard of medicine and to maintain the true honor and dignity of medical science. But at the meeting in New Orleans it did come about that a few ambitious schemers, (I will not say political intriguers) made their appearance (by proxy) desiring to get control of the Association, and to use it in their own preferment and distinction, to the exclusion of members fully their peers in every essential quality of medical and scientific culture, and because their schemes were resisted and frustrated as selfish and sectional, and the Association held true to its honor and representative national character, these discomfited schemers have resorted to every misrepresentation to injure the Association and to make the meeting of the International Medical Congress in this country in 1887 a failure. Can any fair minded man conceive of any course more despicable on the part of physicians claiming to be honorable and the leaders of medical thought?

Now, in good faith, what was the real offence given by the Association at the meeting in New Orleans? It did not displace any one of the seven the Committee appointed at its meeting in Washington in 1884. It simply added others, enlarged the Committee to make it more representative of the entire medical profession of the United States, in whose name the Association had extended the invitation to the International Medical Congress, and to this Committee thus enlarged, the power was given to revise the work already done, and to perfect and complete every arrangement for the successful meeting of the Congress in Washington City in 1887. Was there "medico political" trickery in the exercise of this clear and undoubted right? Was there anything in it that should have wounded the feelings and given offence to any honest medical worker, unselfishly laboring for the advancement of true medical science and the good of the whole profession? It strikes me there was not, that the action taken, was open, frank and fair dealing, and absolutely required to keep the Association true to its representative character and the high and honorable standard of medical ethics, incorporated in its very being—the *lex non scripta* of every honorable medical man in this and every other civilized country

But here is the point of friction, and the origin of this trouble It is well known that a body of ambitious medical men and specialists in the City of New York, believing themselves to be superior to the American Medical Association, of which they were members, boldly undertook to set aside the Code of Ethics and proclaimed their right to hold professional consultations with irregular practitioners of medicine of every description The National Association, as in duty bound after this revolutionary procedure, refused to admit their delegates, and this proper action of the Association was endorsed by every State Medical Society[1] But, these eminent men of New York, justly honored for their high medical attainments, have assumed to stand at the head of the medical profession and to control and govern medical thought and action, and have used every opportunity and means ever since, to justify their antagonism to the Association How well they succeeded, at least for a season, is shown in their capture of the Committee of Seven, the appointees and agents of the Association, and so controlling their action as to have themselves placed above the Association, and so adroitly laid their plans as to draw in the *Medical News* of Philadelphia, which, although professing to love the *Code of Ethics* and be a friend of the Association, has written and said more to injure and break down both, than all other medical journals combined, not excepting the two leading journals of New York, the open enemies of the Code of Ethics and the Association The *Medical News*, not content with sowing the seeds of discord and strife among the physicians at home, has sedulously used its influence in foreign countries, there disseminating misrepresentations of our divisions, to prejudice the medical mind of all Europe against the Association, and thereby prevent a successful meeting of the International Congress, unless these ambitious schemers of New York and their allies can dominate the entire medical profession of this country, and use the Association to further their own personal preferment The bitterness of the *Medical News* is further evinced in its eager hunt after and republishing of every disparaging paragraph and sentence that has appeared in the medical journals of the country whose editors have hoped to gain notoriety and greatness by aping the *News* and the New York journals in their abuse of the action of the Association, when, in fact, they have been outrageously misrepresenting the views of their readers and the medical sentiment of the country, much to their injury and the mortification of their friends

We cordially and heartily appeal to the profession, and beg that they will send as delegates to the Association, in May, their very best men, men of culture, of broad conceptions and conservatism, and of mental and moral stamina, and that while every manly and honorable effort shall be honestly made to pacify and harmonize all of our dissensions, the honor and dignity, the authority and the National and representative character of the American Medical Association will be triumphantly sustained

RICHARD H DAY,
Ex-President Louisiana State Med Soc
Baton Rouge, La , March 7, 1886

NECROLOGY

ALEXANDER Y P GARNETT, JR , M D

The record left behind us when death comes is the heritage of our friends, and in part the legacy which belongs to society Hence it is meet and proper that the good deeds, exemplary conduct and noble character of those who die should be transmitted to posterity as an example to follow and a career to emulate Recognizing this truth, we are unwilling that the untimely death of Dr Alexander Yelverton Peyton Garnett, Jr , which occurred on the 12th of March, 1886, in Washington, should receive only the brief mention of that event

Dr Garnett was born in Washington, on September 18, 1855, received his academic education at the institution of Mr Charles B Young, subsequently graduating in the old William and Mary College, of Virginia He was always of delicate physique, and when but 17 years of age he was sent to Southern California, where he spent one year, returning home in apparent robust health After being graduated at William and Mary, he commenced the study of medicine with his father, in Washington, and matriculated in the National Medical College, in Georgetown, D C , from which he was graduated two years afterwards He then entered the Medical Department of the University of New York, from which he graduated in the following year, and obtained a position in the Charity Hospital of New York Returning home in 1885, he associated himself in the practice of his profession with his father During the short period his health permitted him to engage in practice, he acquired a phenomenal popularity—courteous, tender, careful, and patient in dealing with his patients he never failed to secure their confidence and esteem In August he was taken with a severe attack of rheumatic fever, which at once developed a severe rheumatic carditis, involving the valves and resulting in dilatation From that date his disease seemed to steadily progress, the distressing and fatal consequences following in rapid succession and terminating in his death on Friday, March 12

In the capacity of Assistant Demonstrator to the National Medical College he had commenced a course which was destined, in the near future, to place him in the highest and most responsible positions In all the relations of life, from his boyhood to the day of his death, he was universally admired and beloved The multitude of letters of sympathy and condolence received by his family from all parts of the country attest the wonderful power he possessed to make friends, and the wide spread sympathy and respect shown by those who attended his funeral manifested the hold he had already taken up on the admiration and regard of his fellow citizens in Washington As an evidence of the high regard in which he was held by his fellow associates in the Colleges and Hospital of New York, he received during his illness testimonials in flowers, and the most affectionate letters Professor William H Welch, of the Johns Hopkins University, thus speaks of him in a letter of condolence to his parents "I wish to tell you my deep sympathy in your great affliction, and to express to you the sincere esteem and attachment which I had acquired for your son I became well acquainted with him during the time he worked in my laboratory in New York His amiable and manly character, his enthusiasm, and the marked ability which he showed in his studies with me led me to anticipate for him a useful and successful professional career"

---

[1] Except the New York State Medical Society

At a special meeting of the Washington Obstetrical and Gynæcological Society, held on Friday, March 12 1886, the following preamble and resolutions were unanimously adopted

WHEREAS, This Society has learned of the death of Dr A Y P Garnett, Jr, who died at his residence in this city after a long and painful illness, therefore be it

Resolved, That in the death of Dr Garnett, Jr, this Society has sustained the loss of a member who was distinguished for his exemplary conduct, his uniformly courteous and genial manners, and for his professional zeal and acquirements

Resolved, That we most deeply sympathize with his sorrow-stricken family, and offer them this expression of our sincere condolence in their great bereavement SAMUEL S ADAMS,
A F A KING, *Pres't* *Cor Sec'y*

At a meeting of the Medical Society of the District of Columbia, the following resolutions were adopted

Inasmuch as it has pleased Almighty God to visit us again with affliction by removing from our midst Dr A Y P Garnett, Jr, who departed this life on the morning of March 12th, therefore

Resolved, That we hereby put upon record our profound sorrow at his untimely death, upon the very threshold of a professional career which gave promise of exceptional brilliancy and usefulness

Resolved, That, as Fellows of the Society, we shall ever cherish an affectionate remembrance of his genial, kindly nature, and lofty, self denying character

Resolved, That we tender to his stricken family our heart felt sympathy and condolence in this their great bereavement, and that we attend his funeral in a body

Resolved, That these resolutions be spread upon our records, published in the daily newspapers, and a copy thereof be transmitted to the family of the deceased THOMAS C SMITH, M D,
Corresponding Secretary

ASSOCIATION ITEMS

AMERICAN MEDICAL ASSOCIATION

The Thirty-seventh Annual Session will be held in St Louis, Mo, on Tuesday, Wednesday, Thursday and Friday, May 4, 5, 6 and 7, commencing on Tuesday at 11 A M

The delegates shall receive their appointment from permanently organized State Medical Societies and such County and District Medical Societies *as are recognized by representation in their respective State Societies*, and from the Medical Department of the Army and Navy, and the Marine Hospital Service of the United States

Each State, County, and District Medical Society entitled to representation shall have the privilege of sending to the Association one delegate for every ten of its regular resident members, and one for every additional fraction of more than half that number *Provided*, however, that the number of delegates for any particular State, territory, county, city or town shall not exceed the ratio of one in ten of the resident physicians who may have signed the Code of Ethics of the Association

Secretaries of Medical Societies, as above designated, are earnestly requested to forward, *at once*, lists of their delegates

Also, that the Permanent Secretary may be enabled to erase from the roll the names of those who have forfeited their membership, the Secretaries *are, by special resolution*, requested to send to him, annually, a corrected list of the membership of their respective Societies

SECTIONS

"The Chairman of the several Sections shall prepare and read, in the general sessions of the Association, papers on the advances and discoveries of the past year in the branches of science included in their respective Sections"—*By-Laws*, Article 11, Sec 4

Practice of Medicine, Materia, Medica and Physiology—Dr J T Whittaker, Cincinnati, Ohio, *Chairman*, Dr B L Coleman, Lexington, Ky, *Secretary*

Obstetrics and Diseases of Women and Children—Dr S C Gordon, Portland, Me, *Chairman*, Dr J F Y Paine, Galveston, Texas, *Secretary*

Surgery and Anatomy—Dr Nicholas Senn, Milwaukee, Wis, *Chairman*, Dr H H Mudd, St Louis, Mo, *Secretary*

State Medicine—Dr John H Rauch, Springfield, Ill, *Chairman*, Dr F E Daniel, Austin, Texas, *Secretary*

Ophthalmology, Otology, Laryngology—Dr Eugene Smith, Detroit, Mich, *Chairman*, Dr J F Fulton, St Paul, Minn, *Secretary*

Diseases of Children—Dr W D Haggard, Nashville, Tenn, *Chairman*, Dr W B Lawrence, Batesville, Ark, *Secretary*

Oral and Dental Surgery—Dr John S Marshall, Chicago Ill, *Chairman*, Dr A E Baldwin, Chicago, Ill, *Secretary*

A member desiring to read a paper before a Section should forward the paper, or its *title* and *length* (not to exceed twenty minutes in reading), to the Chairman of the Committee of Arrangements, at least one month before the meeting —*By-Laws*

Committee of Arrangements —Dr Le Grand Atwood, St Louis, Missouri, *Chairman*

AMENDMENTS TO BY-LAWS

By Dr Foster Pratt, Mich —Each Section shall nominate its Chairman and Secretary—all other nominations to be made, as now, by the nominating Committee

By Dr I N Quimby, N J—Create a new Section, to be known as the Section on Medical Jurisprudence WM B ATKINSON, M D,
Permanent Secretary
1400 Pine St, S W cor Broad, Philadelphia

RAILWAY FACILITIES TO THE ASSOCIATION MEETING —The regular through trains of the Illinois Central Railroad from Chicago to St Louis will afford excellent accommodations for delegates who wish to attend the meeting of the American Medical Association at St Louis the first week in May The night express, with Pullman sleeping cars, leaves Chicago at 8 30 P M, and arrives in St Louis at 7 A M The rates are full fare going and one-third for returning

The rates on the Baltimore and Ohio Railway for those coming from the East and South east are full fare coming and one-third fare returning

MISCELLANEOUS

QUARANTINE INSPECTIONS ON THE NORTHERN FRONTIER OF THE UNITED STATES —Official information having been received that the small pox, which recently prevailed as an epidemic in some of the provinces of the Dominion of Canada, is now under control, therefore the regulations issued October 10, 1885, for the maintenance of quarantine inspections on the Northern frontier of the United States, are hereby revoked JOHN B HAMILTON,
Supervising Surgeon-General

AT THE special meeting of the Fifth District Branch of the New York State Medical Association, held in Yonkers on Tuesday, March 23, 1886, it was unanimously resolved that this Branch express its feeling upon the death of the late Austin Flint, M D, as embodied in the following report of its committee, Drs A L Carroll and E H Squibb

The Fifth District Branch of the New York State Medical Association desires to record its unfeigned grief at the decease of its most distinguished Fellow and Founder

In the death of Austin Flint, M D, LL D, a loss has befallen the medical profession which will be sadly recognized as almost irreparable, not only in America, but throughout the civilized world Few men of this generation have done so much to exalt the dignity of our chosen calling, and both at home and abroad, all who knew him conjoined with reverence for his intellectual power and scholarly attainments a sense of personal attachment Whether as an exponent of scientific medicine or as an exemplar of professional integrity and private virtue, he stood conspicuous among the best of his contemporaries, and at the ending of a life without reproach, of a career lavish in benefactions to mankind and rich in well-merited honors, no enmity will slur his memory, no jealousy dispute his leadership

J G PORTEOUS, M D, E H SQUIBB, M D,
President *Secretary*

PALATABLE QUININE, REMARKABLE TOLERANCE —DR E F INGALS, of this city, recently ordered for a child two years of age fifteen tablets of quinine with chocolate, each containing one grain of quinine. One half of a tablet was to be taken three times a day Shortly after the administration of the first dose the child secured the box and ate all the tablets, thinking it candy *No evil effects followed*

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY FROM MARCH 20, 1886 TO MARCH 26 1886

Asst Surgeon John J Cochran, ordered for duty as Post Surgeon, Ft Mason, Cal

Asst Surgeon A S Polhemus, ordered for duty at Presidio of San Francisco, Cal (S O 18, Dept Cal, March 15, 1886)

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U S NAVY DURING THE WEEK ENDING MARCH 27 1886

Martin, H M, Surgeon, detached from "Independence" and ordered to the "St Louis"

Guitéras, D M, P A Surgeon, detached from Navy Yard, Pensacola, and wait orders

Ross, J W, Surgeon, detached from special duty at New York, and ordered to Pensacola

Eckstein, H C, Surgeon detached from the "St Louis" and placed on sick leave

Means, V C B, Asst Surgeon, detached from the "Vermont" and ordered to the "Shenandoah"

Beaumont, N H, Surgeon, detached from the "Enterprise" and wait orders

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U S MARINE HOSPITAL SERVICE FOR THE TWO WEEKS ENDED MARCH 27 1886

Wyman, Walter, Surgeon, detailed as chairman of Board for physical examination officer Revenue Marine Service March 27, 1886

Sawtelle, H W, Surgeon, granted leave of absence for thirty days March 27, 1886

Irwin, Fairfax, Passed Asst Surgeon, granted leave of absence for seven days March 22, 1886

Ames, R P M, Passed Asst Surgeon, detailed as recorder of Board for physical examination officer Revenue Marine Service March 27, 1886

White, J H, Asst Surgeon, granted leave of absence for three days March 23, 1886

Bailhache, P H, Surgeon, detailed as chairman Board of Examiners March 15, 1886

Fessenden, C S D, Surgeon, detailed as member Board of Examiners March 15, 1886

Purviance, George, Surgeon, detailed as recorder Board of Examiners March 15, 1886

EXOPHTHALMIC GOITRE, DYSPEPSIA, PROGRESSIVE MUSCULAR ATROPHY, CHRONIC DIARRHŒA

A Clinical Lecture Delivered in Jefferson College Hospital on February 25,

BY ROBERTS BARTHOLOW, M D ,

PROFESSOR OF MATERIA MEDICA AND THERAPEUTICS IN THE JEFFERSON MEDICAL COLLEGE AND PHYSICIAN TO THE HOSPITAL

The first case, gentlemen, that I will bring before you to day, is one that will well illustrate the method of therapeutics as based upon a physiological basis, about which I have already spoken to you on several occasions Exophthalmic goitre, as you no doubt are aware, is a disease characterized, so to speak, by four sets of symptoms we have an implication of the eyes, they are prominent and protruding, we have an implication of the thyroid gland, which is hypertrophied, we have a dilated condition of the blood-vessels generally, and we have the heart affected, in so far as its action is increased in frequency and in force We have, then, this complexus of symptoms in typical cases, but of course it is not in every case that we have all of them present In this case, for example, there is no protrusion of the eyes, though the other symptoms are all well marked

Now observe this young man's general appearance, if you please, see his type of skin, now he is sitting quiet and has been for some time, and yet you notice that his skin is redder than it should be normally When he makes any exertion, simply that of walking, or goes into a warm room, there is a very decided flushing, not only of the face, but of the whole body, in other words, there is at all times a dilated condition of the peripheral vessels, which is increased by the least exertion Such a state of the cutaneous circulation is always present in this disease, and the temperature is naturally higher than it is in health, which you would expect Well then, we have also an increased rapidity and force of the heart's action, which is really a compensatory augmentation, made necessary by the dilatation of the peripheral vessels, in order that the circulation may be properly maintained therein Well now, where shall we look for an explanation of these phenomena, which we must recognize as due to a paresis of the vaso motor nervous system? well, so much for this cause, but that we may have a comprehensive view of the disease, we must endeavor to look further and ascertain, if possible, what has been the ultimate cause of this paresis of the vaso motor system There seems, from clinical experience, no grounds for doubt that some mysterious and as yet but imperfectly comprehended connection exists between this hypertrophied condition of the thyroid gland and the paretic condition of the vaso motor system Just how the connection acts we are not prepared to say, but that it does exist I think there can be no doubt

As I have already said, in this case we have no protrusion of the eyes, but we have a marked enlargement of the right half of the thyroid gland When I place my fingers over this gland I can detect a very distinct pulsation therein, not confined to the skin alone, for, on somewhat deep pressure, I can also feel this pulsation deep down in the tissue of the gland itself Now I have said that this gland exerts a mysterious influence, let me revert to it again for a minute You are all no doubt familiar with the fact that very peculiar effects follow the removal of the thyroid gland, and you have also, no doubt, heard of the disease called myxœdema, which is characterized by, and is the result of, atrophic changes in this gland, just the reverse of what we have in this case So that you see this body certainly must play some important part in the economy, though just what it is we do not know Here, instead of atrophic, we have hypertrophic changes, and the vaso motor nervous system affected in consequence

Well now, as I have said, we will treat this case from a physiological basis, we will use such drugs as are calculated to antagonize the conditions that are here present In my didactic lecture this morning I was discussing the therapeutic properties of the two drugs, nitrite of amyl and nitro glycerine, and I told you that if you were to administer nitrite of amyl to a patient you would produce, in consequence thereof, a fulness and a throbbing of all the blood-vessels, just such a condition as we see so well marked in the case before us, therefore, reasoning from a physiological standpoint, we should obviously employ such drugs as are calculated to oppose, to antagonize this condition Well now, what drugs are the antagonists of such articles as nitrite of amyl and nitro glycerine? We have several, prominently among them being ergot, which not only theoretically opposes this action, but which has been amply demonstrated by clinical experience to do so Dr Barnes, of London, has reported cases of hour glass contraction of the uterus—which is a condition that may be likened to that produced by ergot, and which is a condition that does not usually readily subside spontaneously—wherein he has secured most satisfactory results from the use of nitrite of amyl, thus very clearly demonstrating the antagonistic action of these two drugs

Having here, then, a condition analogous to that which would be induced by the use of nitrite of amyl, it is obviously logical, arguing from the basis of the antagonism of drugs, that we should employ ergot to combat such a condition I will therefore order ergot for this patient, and I ask, is there any other drug that has this same character of antagonistic action? to which I answer, yes, that such virtue is undoubtedly possessed by digitalis, so that I will order a pill containing two grains of Squibb's aqueous extract of ergot, and one grain of powdered digitalis leaves, one of these pills to be taken thrice daily Well, now, when we have ordered these pills have we performed our full measure of duty? No, by no means We must then direct our attention to the enlargement of the thyroid, for the ergot and the digitalis are intended to combat the abnormal state of the circulation

When he throws back his head you can plainly see how decidedly enlarged this gland is To reduce this enlargement, I know of no better remedy than the local use of an ointment of the red iodide of mercury, which will usually relieve a thickened, hypertrophied condition of the thyroid The Indians, from whom we have derived this remedy, always rubbed it in in the direction of the rays of the sun I do not know whether this procedure has any superiority over any ordinary method of applying it, but it can certainly do no harm, and we might resort to it The patient might sit in front of a window, so that the rays of the sun would fall on his throat There are certain rays of the sun outside of the solar rays, that is to say, the chemical or actinic rays, that certainly do have an influence on vegetable life, and may have some influence on animal life, and we might as well avail ourselves of any influence that these rays may possibly have, for, as I have said, they can do no harm I said to use an ointment of the red iodide of mercury Now, a word of explanation will be necessary, or else you may be misled by what I have said This ointment was officinal in the Pharmacopœia of 1870, but is not so in that of 1880, but you can easily make an ointment by using one drachm of the mercury to one ounce of simple ointment, and take a piece the size of the end of your thumb and rub it well in Do this once a day until the skin becomes sore After awhile you will notice that the skin will become dry and the epidermis will peel off, but this does no harm You may then suspend the ointment for awhile, recommencing it later and using it a little more cautiously than at first

DYSPEPSIA

This young man comes to us complaining of vomiting This may seem like a trivial case to bring before you, and the man does not look as though he was very ill, but it is just these apparently simple cases that will baffle you if you do not cultivate the habit of critically inquiring into their cause and nature You must not despise small matters, for if you do you will frequently overlook greater ones There are several points of interest about this case He tells us that he vomits some time after eating, and that the ejected matter is liquid and occasionally there is some solid matter mixed with it When he was in the waiting room awhile ago he was given a draught of water, and after about half an hour it was regurgitated Now there is a difference between vomiting and regurgitation that I will explain to you In vomiting there is not only a contraction of the stomach, but the abdominal muscles also take part in the act, whereas in regurgitation it is only the stomach and œsophagus that are involved, and regurgitation may occur without any implication of the stomach even, being simply an inversed peristaltic action of the œsophagus We will sometimes have cases where the œsophagus is dilated, where a pouch is formed in some portion of its course, from which the food, after remaining therein for a time, is regurgitated Such is not the case here, for the contents of the stomach itself are regurgitated That is the problem that confronts us, namely, to find out why this regurgitation takes place, and until we have done so, we cannot hope to institute a rational course of treatment that will inure in the least to the patient's benefit

The matter regurgitated is, as I have told you, liquid, and I assume that the man has a form of dyspepsia Well, what form is it? If we were to give this man remedies directed to the relief of the vomiting, even though we were to restrict his diet, as such restriction is usually understood, we would most likely fail to effect a cure, because there is a special indication in the case that must be taken into consideration, and it is just here, in recognizing and appreciating the significance of these little symptoms, that the superiority in diagnosis and the greater success in treatment of one physician over another is to be found We must work out our therapeutics on the fundamental principle that the matter here regurgitated is liquid, hence the patient must be restricted to a dry diet, he should confine himself to solid aliment, and take only that amount of liquid that is absolutely necessary to the proper performance of his functions Of course, he could not absolutely abandon liquids, for they seem to be really more essential to health and life than do solids This fact was abundantly demonstrated by Dr Tanner, in his famous fast He found it comparatively easy to get along without solid food, but his great trouble was in giving up liquids, so much so that after seven or eight days his desire, his longing for them, became well-nigh irresistible So that I say water is really more essential to the performance of the functions than is solid food, we could get along for a longer time without solid foods than we could without liquids When we do not use liquids, the liquid constituent of the blood becomes very much diminished thereby, the blood, in consequence, is thickened, and so an embarrassment of the circulation ensues Taking this fact into consideration, it would not do to rigidly exclude liquids from this man's diet, but, to repeat, he should take them only in such quantities as are absolutely essential. He should take no fluid at meals, unless it is necessary to aid him to masticate his food, and then he should take only a few drops at a time. He should also avoid all articles that are liable to undergo fermentation in the stomach. He doubtless eats fats, which undergo fermentation, with the liberation of butyric acid, and also, no doubt, saccharine articles, that liberate acetic acid and carbonic acid gas, and I will venture to say that he is troubled with eructations of gas, well now, he should avoid such articles. To summarize, his diet should be dry and should consist of such articles as are free from saccharine and oleaginous matter. Now, in addition to the regulation of the diet, which is the most important consideration, what drug can we use? I have, in such cases, derived very good results from the use of sulphurous acid (mind, I say sulphur*ous* and not sulphur*ic*), of which we will give him ten drops (of the dilute acid) in a wineglass of water, thrice daily, before meals. This drug, in conjunction with the regulation of the diet, will do a great deal of good.

PROGRESSIVE MUSCULAR ATROPHY

The characteristic attitude of this woman's hands is so striking that we have no trouble in making a diagnosis. You see that she has wrist drop, but I do not say that she is suffering from lead poisoning, with which trouble you might, at first sight, confound this condition, because she is not so affected. You must remember that there are many varieties of wrist drop. So far as the cause is concerned, the condition is not always due to plumbism, and you should bear this fact clearly in mind, else you will be often misled in your diagnosis. You will also note how all the muscles about the fingers, the interossei very perceptibly, are wasted. When I examine the shoulder, I feel the spine of the scapula very prominent, while both above and below it, more especially below, there is a marked depression, which tells me that there is a wasting of the muscles in this region. She can raise her arm from her shoulder, by which I know that there is still power in the deltoid, but this power is noticeably diminished. Now, then, we have evident wasting or atrophy of the muscles in a muscular young woman, who works in a manufacturing establishment. It is a case of progressive muscular atrophy.

This disease is not very common in women, but it does quite often occur in men under just the conditions that we have here, that is to say, it usually occurs in strong, muscular men, and is the result of some over exertion. It is sometimes hereditary, that is to say, a tendency to atrophy may be inherited, and in such cases over-exertion will light up the latent inheritance into activity. It will be observed, that is this tendency, in certain family groups. It nearly always commences in the fingers, and first manifests itself by sensations of pain and trembling of the fingers and hands. So also, in these parts, there is always a reduction of temperature. Now we will test the electrical reaction of the muscles, you see that every interruption produces a contraction of the muscles, but it is impaired, it is not as marked as normal, and it is confined to certain groups of muscles, but although the muscles are much wasted, they yet respond fairly well to the faradaic current, they react quite well to the direct, but less so to the indirect current. Well, now, what does this response indicate? It tells us that all the muscular elements are not gone, that while the muscular tissue is, to a great extent, replaced by fibrous tissue, it is not wholly so usurpated, and this is a point of exceeding great importance, for upon the loss or the conservation of this reaction will our prognosis depend. Since we find that the muscular tissue still remains, we may hope to rejuvenate it. I would say that in this case there is wasting of the muscles, and that while the response is feeble, yet they do respond to direct faradaic excitation, and much more readily to galvanism. We have, then, a condition where the muscles are not completely changed in character, but are mainly atrophied, the muscular elements are in fairly good condition, and we may therefore hope to benefit the patient. Let us see what the difference in temperature is, and for this purpose we will use one of these surface thermometers that are made by Hawkesley, of London, and are so arranged that a large surface of mercury is exposed to contact with the skin. We might make comparative observations of temperature, if we wish, though it is sufficient for all practical purposes to know that it is lower in the affected part, and we usually find it several degrees lower. In this case we find the temperature of the cheek to be 99°, while that of the thumb is only 92°, a difference of seven degrees, which is very great even in this disease.

The question of the seat of the lesion in progressive muscular atrophy has been greatly discussed and is, as yet, unsettled. One of the latest authorities who has written on the subject is a distinguished professor of Heidelberg, who has contributed a lengthy monograph, in which he claims that the disease really begins, that the lesion is situated at the point where the disease first becomes manifest, that it is situated in the terminal filaments of the motor nerves, and that it is transmitted to them through the muscles, having been really in the first place an affection of the muscles themselves, from which theory the disease would seem to be rheumatic somewhat in nature. The opposite view is that the lesion is situated in the multipolar ganglion cells of the anterior cornuæ of the spinal cord. This case would seem to indicate that the theory of the Heidelberg professor was the correct one, for the electrical responses would cause us to think that the disease was purely a local one, and consisted simply in an atrophy of the muscles without, as yet, any implication of the nerves.

Well, now, assuming this to be the correct theory, what treatment would be indicated? Well, as the muscles respond to the faradaic current, it would be obviously proper for us to excite them thereby until they are restored to their full volume and normal reaction. If they did not respond to faradism we would employ galvanism, but as they do respond to the former, it will be used. Well now, is there anything else we can use in addition to electricity? Yes, we can probably accomplish a great deal by local medication, we will inject $\frac{1}{60}$ of a grain of strychnia into the affected muscles about three times a week, and will also look to improving the general health.

CHRONIC DIARRHŒA.

This young man tells us that he has chronic diarrhœa, that is, to speak more correctly, he will have attacks of diarrhœa every now and then, which will last for several days each time. The stools are liquid, watery and yellow in color. He is never constipated, the passages being always more or less soft in consistence. I have brought the case before you more especially to speak of its treatment. The discharges contain no pus, no blood and no mucus. Now, here again we will base our treatment of this case upon physiological principles. There is evidently a congestion of the intestinal mucous membrane, and we ask what drug will combat such a condition. There is none better than belladonna, and we will give this patient 15 drops of the tincture thrice daily, we will give it alone, that we may unequivocally note the effect. Belladonna is sustained in its action, and it may therefore be that after a while two doses will be found to be sufficient.

ORIGINAL ARTICLES.

EARLY AND REPEATED TAPPING IN CASES OF ASCITES.[1]

BY AUGUSTUS P. CLARKE, M.D.,

OF CAMBRIDGE, MASS.

I was called on March 17, 1879, to attend A. V. S., a Hollander, aged 56 years. He was a cabinet-maker, and while returning a distance of two miles from his work began to suffer from a severe attack of dyspnœa. He had always been well until that time, when he walked somewhat faster than usual. The walking seemed to be the first exciting cause of his malady. When I saw him he was quite unable to lie in a horizontal posture on account of the extreme dyspnœa. Counter irritants, expectorants and stimulants, with ammonia, afforded some relief, and the next day he was much easier.

I did not visit the patient again until January 20, 1880, when I was called, and learned that he had suffered much in the meanwhile from occasional attacks of dyspnœa, as well as from œdema of the feet. At this time he was suffering from orthopnœa. His feet and legs were greatly swollen, and his urine was scanty, the amount voided in twenty-four hours being not much over a pint. The urine, when boiled, gave a precipitate of albumen, one sixth, the specific gravity was 1014. Both lungs were evidently more or less œdematous, and this appeared to be the cause of the orthopnœa. The patient also suffered a good deal from cerebral symptoms, he was delirious, and unable to sleep, and hypnotics acted badly. He had always been of temperate habits. He also suffered from dimness of vision, the ophthalmoscope revealed marked retinitis of both eyes. The infusion of digitalis in full doses was given, and followed up until the physiological and therapeutical action of that drug was obtained. Elaterium in pill, gr. ⅙, was given every second or third day. Sometimes the pill had to be repeated the same day. I also scarified the legs and feet from time to time, and by this means I succeeded in reducing the swelling very much. My record shows that I made upwards of a thousand punctures with the lancet. The scarifications were followed by no untoward symptoms, and the patient often requested the scarifying to be done for the relief afforded.

Subsequently Martin's elastic bandage was applied to each leg from the toe to above the knee. These afforded him a good deal of relief, and after he had learned their uses and value he would rarely be without them. His symptoms at length became better, the swelling of the extremities was markedly less, and the dyspnœa much less urgent. The action of the lungs became more regular, and the pulse and temperature were nearly normal, but he began to suffer more from ascites, and though the diuretics and hydragogues were freely employed, they had but a limited influence on the fluid effused into the peritoneum. Fluctuation became distinct, but I waited until August 20, 1880, when with the aspirator I removed four quarts of fluid from the cavity of the peritoneum. This gave the patient considerable relief, and on September 11 I again drew off eight quarts. The patient bore the loss quite well, and afterward appeared much better.

On October 13 I drew off with a small trocar five quarts. On November 14 I drew off four quarts, and January 18, 1881, I drew off with a larger trocar 8½ quarts, March 18, 11½ quarts, April 21, 15½ quarts, May 14, 16 quarts, June 10, 18 quarts, July 16, 16 quarts, August 6, 14½ quarts, September 3, 16 quarts, October 1, 17½ quarts, October 28, 13 quarts, January 5, 1882, 12 quarts, February 10, 14 quarts, March 14, 14½ quarts, March 27, 17 quarts, April 17, 18 quarts, May 8, 17 quarts, May 22, 13½ quarts, June 5, 12 quarts, July 11, 14 quarts, August 22, 12½ quarts, March 30, 1883, 11½ quarts (after a period of six months and eight days), August 14, 14½ quarts (after a period of five months), September 7, 12 quarts, October 21, 15 quarts, December 17, 13 quarts, January 25, 1884, 14½ quarts, February 29, 15 quarts, April 7, 17½ quarts, July 7, 13½ quarts, October 3, 13 quarts, November 19, 16 quarts, December 17, 12 quarts; February 21, 1885, 13 quarts, and April 17, 13 quarts. The number of tappings, including the two aspirations, was in all thirty eight, and the quantity of fluid removed by this means of treatment amounted in all to 506½ quarts (32 fluid ounces contained in each quart, or 126⅝ gallons).

After each tapping the patient was always better, and was often able to go out of doors, especially in warm weather. Soon after I began to tap him he gained in strength, nearly all the œdema of his lower limbs disappeared, his appetite became better, and for the most part he needed no quieting medicine, indeed, he took but little medicine after this line of treatment was adopted The patient also began to take quite a lively interest in various matters, such as reading the daily papers, until the accumulation of fluid become excessive The urine became of higher specific gravity, for a long time, on boiling, was only a little opalescent, and there was a tendency to a return of its normal constituents The quantity of urine for a healthy person was only approached, it never exceeded 1,000 cc, and for the most part was only 500 cc daily Accurate measurements were kept for a long period daily Whenever the quantity of urine for any considerable time was increased, the symptoms and condition became much better, and whenever the quantity of urine was markedly less, say between 400 and 500 cc, the patient was more uncomfortable

---

[1] Read before the Cambridge Society for Medical Improvement, January 25, 1886.

The longest period between the tappings was six months and eight days This was from August 28, 1882, to March 3, 1883 The next longest period was that of five months, from March 3 to August 4, 1883 During these periods the patient took from time to time a good deal of fluid extract of jaborandi and of ergot The patient felt so far recovered for awhile as to be out a little almost every day The urine during this time was greatly improved and he gained in strength For several weeks the circumference of his abdomen over or just below the navel was no more than it often would be three or four days after a tapping Toward the close of these periods the fluid increased quite rapidly, and the tension became intolerable The patient usually recovered well after each tapping Sometimes, however, he would feel a little weak, but a small draught of wine or of milk, or sometimes only water, was all that was needed to revive him He usually kept his lounge or bed for a day or two, and then dressed himself as usual A short time before he was tapped in December, 1884, he met with a severe fall down a long flight of stairs He was severely contused about the right shoulder, left hip, leg and other parts, but he sustained no marked injury upon the abdomen

During the early part of his sickness he had considerable febrile disturbance, the pulse often going as high as 115, and the temperature as high as 101 5° to 102° F, but for a long time before his death the pulse was normal or nearly so, and there was no rise of temperature Immediately after being tapped the temperature would occasionally be slightly sub normal At first the patient suffered very much from constipation, but for the last three years of his life the bowels were very regular Though the urine was scanty, and at first highly albuminous, very few casts of any kind were observed, or other abnormal products of a microscopic character After he was tapped he assumed the horizontal posture

The liver, for the last two years or more, could be distinctly felt as a hard and contracted globular mass high up in the right hypochondriac region It was evidently not more than one half the natural size At first the area of the liver by percussion appeared to be unusually extended, and this increased size at first, occasioned by congestion or inflammation, would account in part for the increased temperature and other febrile disturbances which appeared so early in the case The diminished flow of the urine was under the circumstances indicative of congestion of the portal vein The increased bulk of the liver, and the commencing ascites and the œdema of the lungs must have greatly interfered with the action of the diaphragm, and have been the cause of the extreme dyspnœa which also so early presented itself

The last six months or more of the patient's life showed a general failing of the vital powers, the appetite was poor, though the patient was not greatly emaciated About May 1 1885, he began to be troubled with dysenteric stools These exhausted him more and more, so that his death could be considered rather as the result of gradual asthenia than of any peculiar lesion or organic phase of the disease The tapping, as already stated, gave immediate relief from the dyspnœa and other urgent symptoms, and the patient, though dreading the operation, at length became satisfied that he could not be comfortable without resorting to it He showed me an account which he had found in reading an old Dutch author, that Peter the Great had saved or prolonged the life of his wife, Eudoxia Feodorovna, by tapping her for a dropsical malady This art, it appeared, Peter had learned by witnessing the operation as performed by the chirurgeons when he was a young man and an inmate in a European hospital This little bit of history served to stimulate my patient by giving hope and confidence in the treatment as the only means for his relief He died on May 13, 1885

In regard to my own experience, reference to the recorded cases of ascites from various causes coming under my care up to the time I was called to treat the case here reported, shows that six cases recovered, one case after a single tapping, one case after three tappings, two cases after four tappings each, one case after three tappings, each tapping varying from two to three months, and one case, that of a lady aged 51, after six tappings, each tapping varying from six weeks to three months There was no sensible return of the fluid in her case after a period of two years After that she left the State for the provinces, and has not to my knowledge since returned One case was that of a man, aged 64, whom I tapped for ascites four times during a period of three years He was greatly relieved, but afterwards died from some abdominal disease complicated with acute pneumonia

Two cases were males, aged respectively 37 and 42 These were phthisical patients, each much troubled with ascites One of them was tapped twice, and the other three times during a period of eleven months They were greatly relieved, but both finally had to succumb to the original malady, which was far advanced before this treatment was undertaken

Another case was that of Miss S, aged 17 She was under my care from July to September, 1878 She had Bright's disease She had previously been under the treatment of two homœopathists for what they at first supposed to be "rheumatism and neuralgia of the spine," until the legs and abdomen began to swell, when they were dismissed and I was called and diagnosticated, with Dr Holt's assistance,

Bright's disease We were compelled to tap her twice within two months, but she finally died in a uræmic convulsion Her abdomen was enormously distended before the tapping This was undoubtedly a case of acute parenchymatous disease of the kidney

Another case was that of a lady aged 60 years She had malignant disease of the stomach She also had ascites The fluid, though moderate in amount, was a source of great suffering, and she required large doses of morphine She was under my care from February 5th to April 25th, 1878, the time of her death I tapped her twice She experienced marked relief from each tapping until the fluid again accumulated, which did not occur until after the lapse of four weeks

The twelfth case was that of Miss P, aged 43 years She suffered from extreme dyspnœa and great throbbing at the neck, which seemed indicative of aneurism Elaterium and digitalis removed all the swelling of the extremities and abdomen This was from November 1 to December 16, 1879, but on December 31 following she had a recurrence of the dyspnœa, with marked ascites Between this date and March 10, 1880, she was tapped twice, with much relief after each operation On April 3 she died in consequence of the enormous aneurism, which after death proved to be at the arch of the aorta

I will now briefly relate a case which has been of unusual interest to me Mr B, aged 76 years, upon whom I had operated three times during the months of May and June, 1884, before I succeeded in completely curing him of old hæmorrhoids attended with severe prolapsus of the rectum After this the patient had entirely recovered, so that he was able to be out as heretofore during the months of August and September In November following he was run over by a heavy express wagon while in Boston, and was afterwards exposed to severe cold and wet, and was chilled On November 11 he was unable to void urine His legs, genitals and abdomen were enormously swollen, and the patient became stupid, his tongue was dry and brown With great difficulty I succeeded, on that day, in drawing off about a pint of urine, which was of a dark, smoky color On the next day he was much worse, was still stupid and unable to comprehend anything of consequence when spoken to, and I found it necessary to slit up the prepuce about an inch and a half before I could reach the urethra with any kind of a catheter whatever, so great was the swelling that had extended to these parts Only a small quantity of urine, however, was found in the bladder With the assistance of the apothecary, Mr H S Andros, who had frequently assisted me in the case of A V S, I aspirated the abdomen and removed four quarts of fluid The next day I tapped again, and the amount of fluid now removed was nearly a water-pailful After that the patient was able to void his urine, and by the use of elaterium he gradually made a complete recovery, except for a troublesome pruritus, the absence of the tendon reflex and a tendency towards locomotor ataxia The patient is able to be out of doors almost daily, and walks quite well Up to the time (1880) when I began to treat my patient, A V S, almost all authorities refer to tapping of the abdominal cavity in ascites to be had recourse to only as a last resort In THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, Vol 1, No 10, will be found an original article "On Early Tapping in Cases of Ascites" This article, by Austin Flint M D, was read at the meeting of the British Medical Association in Liverpool, on August 2, 1883, and which was about three years after I began to treat my patient, whose case I have given *in extenso* at the beginning of this paper Dr Flint, in speaking of the advantages of early tapping in cases of ascites, gives a report of twelve cases illustrative of the benefit of such tapping He refers to a series of forty six cases in an article "On Hydro Peritonæum," which he published in the *American Journal of Medical Sciences* in the year 1863 In his article of 1883 he again states that more writers than heretofore recommend tapping in cases of ascites "only when the dropsical accumulation has occasioned an alarming interference with respiration, and after other means of treatment have proved ineffectual" In a foot-note he mentions "as exceptional instances" some cases occurring in Dr Frederick T Roberts's "Hand-Book of Medicine"

QUININE IN SCIATICA—UNUSUAL SUSCEPTIBILITY TO MORPHIA, WITH TOLERANCE OF THE DRUG

BY WM G EGGLESTON, M A, M D,

OF CHICAGO ILL

The average length of time, I believe, required for a subcutaneous injection of morphia to take effect as an anodyne is about fifteen minutes, for the hypnotic effect a still longer time is required The following case is interesting on account of the facts that the drug acted in a remarkably short time, and that at times there was no appreciable interval between the anodyne and hypnotic effects, and on account of the favorable action of quinine in a case of sciatica

On March 13, at 8 P M, I was called to see A F H, æt 54, who who was suffering from a severe attack of sciatica on the right side For sufficient reasons I administered morphia, gr $\frac{1}{6}$, with gr $\frac{1}{200}$ of atropia As usual when I administer any drug subcutaneously I noticed the time While replacing my syringe in the case the patient threw his arms across his chest, said "All right," and was asleep immediately This was just four minutes after the injection was made Being somewhat alarmed at such unusual susceptibility, I aroused the patient and spoke to him I had no difficulty in awakening him, and he seemed surprised that I had aroused him He said that the drug had had a similar effect two or three years ago when he had taken it, and his wife confirmed his statement Upon this information I determined to set aside my proposed treatment of the case with injections of ether, and to use morphia, with cod liver oil and phosphorus internally

On the next day, March 14, I administered gr $\frac{1}{6}$ morphia, with gr $\frac{1}{200}$ of atropia, at 9 A M The patient had slept well the night before until about

3 30 A M , after which the pain began to return slowly The injections were made superficially behind the right trochanter on the affected side Within three minutes the patient announced that he "felt it" in his arms—"a kind of numb feeling down through the elbows" Within another minute he said that he was perfectly easy This time, however, he did not fall asleep Another injection was made in the evening, the pain being annoying, but not so great as on the previous afternoon Within a few seconds less than four minutes he began to say that he felt better, but was asleep before the sentence was completed In the morning he had commenced taking teaspoonful doses of cod liver oil and phosphorus (gr i–f℥jss)

March 15 —Patient said that he had misinformed me as to the element of periodicity in the attacks of pain before I was called in He now remembered that the first attack, about five days previously, had come on at 8 P M , the second about 7 30, the third a little earlier, and the attack on the previous day about 5 P M I ordered bisulphate of quinine gr xxx, one half to be taken at 2 P M , the remainder at 4 o'clock

March 16 —The pain did not come on yesterday afternoon, and the patient slept all night The quinine made him "pretty drunk," he said, and yielding to his very earnest desire I ordered none for this afternoon The pain came on at 5 30 P M , and I gave morphia at 7 30 As before, he was at ease and asleep in four minutes The only subjective sensation was the numb feeling down the arms There was no nausea whatever, and no itching of the nose I ordered bisulphate of quinine as before, to be taken at 2 and 4 P M

March 18 —No pain yesterday Quinine continued for to day Phosphorus in oil reduced to gr $\frac{1}{50}$ at a dose

March 19 —No pain yesterday Quinine continued for to day, two doses of gr x each

March 24 —There has been no return of pain, and the patient has been at work since March 20 He continues the cod liver oil and phosphorus (now gr $\frac{1}{100}$ at a dose), and is taking Fowler's solution, gtt vj after each meal His appetite is excellent, bowels perfectly regular Ordered pil hydrarg gr v to be taken on the first appearance of furred tongue or irregular action of the bowels, and to be followed on the next morning by a Seidlitz powder

March 29 —He reports that he is still improving, and there has been no pain whatever

In regard to the use of cod liver oil in sciatica Anstie has long laid much stress on its importance, as has Dr Ashburton Thompson Anstie insists that fat must be liberally taken So also, in regard to the use of phosphorus, Dr Thompson has used and recommended it for some time He gives it in solution in cod liver oil, gr j—f℥jss One drachm of this is given every four hours The solution is best made by adding the pharmacopœial phosphorated oil to the cod liver oil Dr Thompson has given a table of fifty cases of neuralgia treated by phosphorus, and in several the effects of the drug seem to have been truly remarkable According to him, if marked results be not seen within three days, it is useless to continue this line of treatment The above recorded case is the second (of sciatica) in which I have recently used phosphorus, in large doses, with cod liver oil I am sure that the first case experienced more direct and immediate relief from ether injections than from the phosphorus, and that the second case was cured by quinine Still, I believe the oil and phosphorus to be valuable parallel and after treatment

The amount of quinine used in this case may be thought by many to be excessive But I think that, as a rule, larger doses of this antiperiodic are required to prevent the recurrence of a severe neuralgia than of an ordinary "chill" Again, many are in the habit of administering quinine in 5 grain doses, and claim that the effects are just as good or even better But it is necessary to use 5 or 10 grains more, as a rule, when it is given in this way A protracted personal experience with "chills" has given me a dislike to small doses of quinine (gr v every four hours) in intermittent affections Nor do I think that the value of quinine in neuralgia is limited to the strictly intermittent cases I recall one case in which a severe case of non intermittent (though probably malarial) trigeminal neuralgia was effectually routed by two doses of gr xxx, on two successive days, though the patient had been taking gr iv three times a day for fully two weeks

At any rate, it must be admitted, as has been shown, that large doses of quinine, given at one time for the antipyretic effect, have a more marked effect on the temperature than the same quantity distributed over a long time, and I see no reason to doubt that the same holds true when the drug is given solely as an antiperiodic It is possible, too, that malarial pyrexia and malarial neuralgia differ only in this in the first the nervous explosion is general, and takes the form of fever, in the second it is localized in one or more nerves and causes pain One reason that has been advanced against the giving of one or two large doses of quinine is that it is rapidly eliminated In three experiments Thau found that about three-fourths of the amount given was eliminated in *twelve* hours[1] I use the bisulphate invariably It is very much more certain in its effects, much more soluble, and its effects are therefore more quickly produced Its solubility, moreover, renders it especially adaptable for hypodermatic administration When thus used the solution should *always be brought to the boiling point* in the spoon immediately before it is taken into the syringe This, I think, is the most certain way to prevent sore spots and abscesses after subcutaneous injections of any drug

In regard to the extreme susceptibility to morphia, with the tolerance, without any bad or unpleasant effect whatever, of a dose which acted so quickly, I think that the case recorded is very remarkable That the imagination of the patient had nothing to do with the rapid effect was shown by the fact that a subcutaneous injection of warm water, given experimentally on the second day, had no effect whatever

65 Randolph St

---

[1] Binz found that about two thirds only was eliminated in 48 hours but his results have been questioned

Bright's disease We were compelled to tap her twice within two months, but she finally died in a uræmic convulsion Her abdomen was enormously distended before the tapping This was undoubtedly a case of acute parenchymatous disease of the kidney

Another case was that of a lady aged 60 years She had malignant disease of the stomach She also had ascites The fluid, though moderate in amount, was a source of great suffering, and she required large doses of morphine She was under my care from February 5th to April 25th, 1878, the time of her death I tapped her twice She experienced marked relief from each tapping until the fluid again accumulated, which did not occur until after the lapse of four weeks

The twelfth case was that of Miss P , aged 43 years She suffered from extreme dyspnœa and great throbbing at the neck, which seemed indicative of aneurism Elaterium and digitalis removed all the swelling of the extremities and abdomen This was from November 1 to December 16, 1879, but on December 31 following she had a recurrence of the dyspnœa, with marked ascites Between this date and March 10, 1880, she was tapped twice, with much relief after each operation On April 3 she died in consequence of the enormous aneurism, which after death proved to be at the arch of the aorta

injection was made Being somewhat alarmed
such unusual susceptibility, I aroused the patient an
spoke to him *I had no difficulty in awakening him*
and he seemed surprised that I had aroused him H
said that the drug had had a similar effect two o
three years ago when he had taken it, and his wife confirmed his statement Upon this information I determined to set aside my proposed treatment of the case with injections of ether, and to use morphia, with cod-liver oil and phosphorus internally

On the next day, March 14, I administered gr $\frac{1}{6}$ morphia, with gr $\frac{1}{200}$ of atropia, at 9 A M The patient had slept well the night before until about

shown, to the hypertrophy of the muscular fibres between the orifices of the ureters—the intra ureteral bar—as well as, I believe, to that of the muscular fibres so largely entering into the composition of the prostate In this, I submit, will be found the immediate cause of prostatic hypertrophy The change being an example of an hypertrophy, its production by conditions favoring the formation of over growths observed in the body seems to be reasonable Such a view, as applied to the large prostate, is strengthened by certain clinical observations A frequent desire to empty the bladder is constantly met with in what is regarded as the earliest stage of prostatic hypertrophy, and long before the gland has assumed any considerable size, the more frequent the calls are to urinate, the more rapidly does the prostate grow, and all circumstances which tend to increase irritability of the bladder may be said to favor the development of this condition Lastly, the only means which are known to have caused the opposite state—namely, that of atrophy, to be engrafted on the hypertrophied gland—are those which for a considerable time converted a muscular and physiological act into a purely mechanical one, for instance, the case I published[1] some years ago (since repeated with equally satisfactory results), where, by the wearing of a canula inserted through the perineum, the process of micturition was reduced to the mechanical act of turning a tap on the part of the patient Though regarding senile enlargement of the prostate as an hypertrophic change, I was at a loss to explain how it was induced until I met with instances where, from the conformation of the bladder, an irritating condition of residual urine seems to have preceded, and not to have been the consequence of, an enlarged prostate Instances in practice are not uncommon in elderly males, where all the symptoms usually assigned to prostatic enlargement are present, without there being evidence, beyond the presence of some residual urine, that any physical change in the gland has taken place

The frequency with which the floor of the gland is the first to show the hypertrophic change seems to strengthen the inference I have drawn from the development of the inter ureteral bar, and to indicate that both conditions are the direct result of straining and an excess of the expulsive action of the bladder and associated parts Structurally, the inter ureteral bar and the hypertrophied prostate are identical, with the exception that in the latter will be found the follicles which have led to it being regarded as a glandular body It is impossible to examine some of the commoner forms of advanced prostatic hypertrophy without being struck with their resemblance to what I would describe as growing casts of the interior of a frequently contracting bladder

But it may be urged that if repeated expulsive action on the part of the bladder causes enlargement of the prostate to follow, how is it that stone and urethral stricture do not in like manner occasion it as a uniform consequence? To this I would reply that stone and stricture as excitants of expulsion are general or varying in their operations, and do not, as a rule, merely involve a limited area of the bladder wall, consequently the hypertrophy following stricture is universal so far as the viscus is concerned In the same way, the whole bladder is involved when a growing prostate becomes in addition an obstacle to micturition When a stone is fixed to the bladder it is I believe, subjected to precisely similar influences on the part of the bladder wall immediately adjacent to it as those described in connection with the trigone, and may result, as I have seen, in a circumferential development of muscular tissue sufficient in some instances to produce sacculation This is not an uncommon process, and may be studied with advantage in those cases where secondary calculi are developed as a consequence of surface irregularities produced by a large prostate, and which I have referred to elsewhere as fixed or stationary stones [1] Further, it may be urged that such an explanation cannot be held to cover those instances where persons with more or less enlarged prostates do not suffer from them I have investigated cases of this kind generally with the result of finding out that, at some period in their history, considerable urinary irritation was present and persistent That an hypertrophy may prove to be *a precise compensation*, without, on the one hand, falling short, or, on the other, overlapping, I think we have evidence of here as in other parts of the body It has been objected that enlargement of the prostate cannot be regarded as a mere muscular hypertrophy, as it does not occur during those periods of life which are most remarkable for muscular activity and development On the other hand, it is hardly necessary to remark that, though an hypertrophic act in which muscular tissue is principally involved, it is really prompted by alterations in the form or function of a contiguous part which are the products of advancing years

It may not be out of place to observe in connection with analogous processes of hypertrophy, which in general terms have been referred to, that the best marked are those where structural defects are remedied, not in the part itself at fault, but in that which is adjacent In the heart it is not the valve that is reproduced, but the ventricle or auricle which is augmented Nor does the analogy cease here, for as the hypertrophied heart in turn occasions symptoms peculiar to itself, in like manner does the large prostate produce its own derangements In conclusion, it should be remembered that the changes and diseases to which the hypertrophied gland is liable, and about which there is much to be said of great practical value, must not be confounded with the primary lesion it is desired here to refer to —*Lancet*, March 6, 1886

Pyridine in Asthma —Dr Joseph Neff, of Philadelphia, in an article on this subject, gives the following summary of his results with this drug

Nervous pulmonary asthma, 3 No return of attacks in any

Cardiac asthma, 3 All were relieved of attacks One remained under observation three months, and one for two weeks only

A CASE OF STRAMONIUM POISONING, WITH PECULIAR SYMPTOMS

BY C C GRATIOT, M D,

OF SHULLSBURG WISCONSIN

Between the hours of 7 and 8 P M on February 22 I was called in haste to see the child of Street Commissioner Thomas Lee, of Shullsburg, the messenger stating that the child was having convulsions I arrived at the house within a few moments and found the patient, a boy three years of age, sitting in his mother's lap, his arms and hands outstretched as though to grasp some object He would open and shut his fingers with deliberation, as though the object he was trying to grasp required some caution and skill to take hold of After two or three minutes of such manœuvreing he would make a sudden jump as though about to seize the object, and would then cry distressfully

While his hands were thus employed his eyes were fixed, looking straight ahead as though watching something The pupils were widely dilated, cheeks flushed, mouth dry, pulse fast and full, heart's action good but fast, and respirations increased

There was also another hallucination He would act as though something was approaching him from the opposite side of the room, and would point towards it his eyes and facial expression would convey the idea that the object was after him, and coming nearer and nearer, until he became so agitated that he seemed on the point of having a convulsion

These hallucinations would alternate, and the only thing that diverted his attention for an instant would be to offer him a cup of water, which he took with a seeming relish Turning down the light until the room was almost dark made no difference in his actions

I was told by the parents that he had always been healthy, that he had been playing out of doors all day, ate a hearty supper, and that nothing wrong was noticed until a few moments before they sent for me, when he commenced to act in the manner described I inquired if there was any medicine in the place that he could have taken, but could find nothing that threw any light on the case While watching him and making these inquiries I noticed that the symptoms were getting worse

It occurred to me that the symptoms were those of belladonna poisoning I administered an emetic of ipecac, gr x, and a large quantity of water He vomited in a short time, but there was nothing unusual in the ejected matters I then gave small doses of morphia and bromide of potassium, and rectal injections to move the bowels, but without effect After an hour he became more quiet, and fell asleep After an hour's sleep he seemed somewhat better The pupils were still widely dilated, but the hallucinations were not so vivid

On telling a professional friend of the curious actions of the patient he remarked that the symptoms were similar to those which he once saw in the cases of two children who had eaten *stramonium*, and it immediately occurred to me that such was the case with my patient He vomited several times during the night, and would wake up and go through his performances, but not so badly as during the evening

On the morning of February 23 he was much better The crazy actions had disappeared, but the pupils were still considerably dilated, cheeks flushed, and he was very thirsty He ate a good breakfast, and before night was apparently as well as ever In the matters vomited during the night were a number of stramonium seed I found on inquiry that his father had kept a patch of stramonium plants in the corner of his yard, which he used in making ointment for horses The boy had cut one of the dry stalks, which was hanging with pods full of seed, and had eaten a quantity of the seed After finding the cause of the child's sickness the mother remembered his bringing the stalk on the porch, and saying that he had cut a tree

The case is of still further interest as showing that stramonium poisoning is quite possible in winter if there be any of the dead plants about with pods full of seed

MEDICAL PROGRESS

Causation and Nature of Hypertrophy of the Prostate —Mr Reginald Harrison gives an interesting summary of his views on this subject as follows In a paper recently published[1] on some "Changes in Form of the Prostate and Floor of the Bladder," I have shown that the inter ureteral bar of muscular fibres so frequently met with in cases of enlarged prostate is to be regarded as the outcome of efforts, by the development of extraordinary agents of micturition, to expel urine from a part where it is apt to lodge and cause inconvenience In connection with these investigations, I have met with instances where an unusually depressed state of the floor of the bladder, or trigone, appeared to me to have existed previously to an enlarged prostate, in fact, that a condition of residual urine preceded, and was not the sequence, of enlargement of the gland The trigone, or floor of the bladder, in addition to being a highly sensitive part, is peculiar in that it contains but few muscular fibres in its composition, muscle in abundance may be found as low as a line corresponding with the openings of the ureters, and marking the superior boundary of the trigone, and below in the prostate, between these two points the power of muscular contraction can hardly be said to exist Assuming that, from any cause, such as long retention of urine, habit, position of the body, or the weakness connected with advancing years, the trigone, or non contractile part of the bladder, becomes permanently depressed or altered in form, so that the person finds himself unable to get rid of the last half-ounce or so of urine, the effect will be frequently repeatedly expulsive efforts in all the muscles immediately adjacent to a part which, by reason of its connections and structure, has no power of exercising contractility This will eventually lead, as I have shown, to the hypertrophy of the muscular fibres between the orifices of the ureters—the intra ureteral bar—as well as, I believe, to that of the muscular fibres so largely entering into the composition of the prostate In this, I submit, will be found the immediate cause of prostatic hypertrophy The change being an example of an hypertrophy, its production by conditions favoring the formation of over growths observed in the body seems to be reasonable Such a view, as applied to the large prostate, is strengthened by certain clinical observations A frequent desire to empty the bladder is constantly met with in what is regarded as the earliest stage of prostatic hypertrophy, and long before the gland has assumed any considerable size, the more frequent the calls are to urinate, the more rapidly does the prostate grow, and all circumstances which tend to increase irritability of the bladder may be said to favor the development of this condition Lastly, the only means which are known to have caused the opposite state—namely, that of atrophy, to be engrafted on the hypertrophied gland—are those which for a considerable time converted a muscular and physiological act into a purely mechanical one, for instance, the case I published[1] some years ago (since repeated with equally satisfactory results), where, by the wearing of a canula inserted through the perineum, the process of micturition was reduced to the mechanical act of turning a tap on the part of the patient Though regarding senile enlargement of the prostate as an hypertrophic change, I was at a loss to explain how it was induced until I met with instances where, from the conformation of the bladder, an irritating condition of residual urine seems to have preceded, and not to have been the consequence of, an enlarged prostate Instances in practice are not uncommon in elderly males, where all the symptoms usually assigned to prostatic enlargement are present, without there being evidence, beyond the presence of some residual urine, that any physical change in the gland has taken place

---

[1] Liverpool Medico Chirurgical Journal July 1885

The frequency with which the floor of the gland is the first to show the hypertrophic change seems to strengthen the inference I have drawn from the development of the inter ureteral bar, and to indicate that both conditions are the direct result of straining and an excess of the expulsive action of the bladder and associated parts Structurally, the inter ureteral bar and the hypertrophied prostate are identical, with the exception that in the latter will be found the follicles which have led to it being regarded as a glandular body It is impossible to examine some of the commoner forms of advanced prostatic hypertrophy without being struck with their resemblance to what I would describe as growing casts of the interior of a frequently contracting bladder

But it may be urged that if repeated expulsive action on the part of the bladder causes enlargement of the prostate to follow, how is it that stone and urethral stricture do not in like manner occasion it as a uniform consequence? To this I would reply that stone and stricture as excitants of expulsion are general or varying in their operations, and do not, as a rule, merely involve a limited area of the bladder wall, consequently the hypertrophy following stricture is universal so far as the viscus is concerned In the same way, the whole bladder is involved when a growing prostate becomes in addition an obstacle to micturition When a stone is fixed to the bladder it is I believe, subjected to precisely similar influences on the part of the bladder wall immediately adjacent to it as those described in connection with the trigone, and may result, as I have seen, in a circumferential development of muscular tissue sufficient in some instances to produce sacculation This is not an uncommon process, and may be studied with advantage in those cases where secondary calculi are developed as a consequence of surface irregularities produced by a large prostate, and which I have referred to elsewhere as fixed or stationary stones[1] Further, it may be urged that such an explanation cannot be held to cover those instances where persons with more or less enlarged prostates do not suffer from them I have investigated cases of this kind generally with the result of finding out that, at some period in their history, considerable urinary irritation was present and persistent That an hypertrophy may prove to be *a precise compensation*, without, on the one hand, falling short, or, on the other, overlapping, I think we have evidence of here as in other parts of the body It has been objected that enlargement of the prostate cannot be regarded as a mere muscular hypertrophy, as it does not occur during those periods of life which are most remarkable for muscular activity and development On the other hand, it is hardly necessary to remark that, though an hypertrophic act in which muscular tissue is principally involved, it is really prompted by alterations in the form or function of a contiguous part which are the products of advancing years

It may not be out of place to observe in connection with analogous processes of hypertrophy, which in general terms have been referred to, that the best marked are those where structural defects are remedied, not in the part itself at fault, but in that which is adjacent In the heart it is not the valve that is reproduced, but the ventricle or auricle which is augmented Nor does the analogy cease here, for as the hypertrophied heart in turn occasions symptoms peculiar to itself, in like manner does the large prostate produce its own derangements In conclusion, it should be remembered that the changes and diseases to which the hypertrophied gland is liable, and about which there is much to be said of great practical value, must not be confounded with the primary lesion it is desired here to refer to —*Lancet*, March 6, 1886

PYRIDINE IN ASTHMA —DR JOSEPH NEFF, of Philadelphia, in an article on this subject, gives the following summary of his results with this drug

Nervous pulmonary asthma, 3 No return of attacks in any

Cardiac asthma, 3 All were relieved of attacks One remained under observation three months, and one for two weeks only

---

[1] British Medical Journal Dec 24 1881 and April 8 1882

[1] Annals of Surgery June 1885

Bronchial asthma, 3 In one there was no return during ten weeks' stay in the hospital The two others were relieved of their attacks and insisted upon their discharge, being under treatment less than three weeks

Asthma in advanced phthisis, 2 In one there was but slight relief during the paroxysm, in the other there was absolutely no benefit

Asthma as a complication of gout, 1 No return in a month Albuminuria from interstitial nephritis was present

Of the fourteen cases reported by Sée, four were in females, ten in males, from 30 to 68 years of age Nine were what he terms "pure asthma," all of which were more or less relieved, and five cases of cardiac asthma

In one case of twelve years' duration pyridine caused nausea and vertigo after eight days of treatment, which necessitated its discontinuance, although great relief was obtained Nausea I have not seen, vertigo but once In one or two cases where the expectoration had been purulent it lost that character after the inhalation All unpleasant symptoms seem to be confined to cases with long standing emphysema, or valvular or degenerative heart disease, with small, irregular pulse In young, robust people with "simple" pulmonary asthma there seems to be drowsiness alone

Since these observations were made I have noted, in a more recent report by Lublinski, one case of marked tremor of the limbs with nausea, and another with vomiting, dizziness, and severe headache In all of these, however, the length of time of each inhalation was prolonged from one to one and one-half hour The beneficial results obtained from this remedy seem to be from its action on the sympathetic and the medulla Any depressing effects on the heart would seem due rather to the interference with the pulmonary functions, death being caused, in the lower animals at least, by paralysis of the respiratory centers

Pyridine is not to be classed as a curative agent Most likely its greatest value will be seen in cases of simple or nervous pulmonary asthma, when the iodine preparations cannot be borne, or nitro glycerine and sodium nitrite are contra indicated Although in the bronchial or catarrhal forms of the disease the relief of the paroxysms has been marked in ninety per cent of the cases treated, of the remaining number nearly all had emphysema of long standing In asthma occurring in advanced phthisis the drug should be given with care on account of the small amount of lung tissue left unaffected, especially where there is a great degree of consolidation with fibroid induration, when, perchance, the spasm may be relieved, but few air vesicles remain in condition to respond Here at least morphine will hardly be superseded

I have used pyridine in several forms of dyspnœa occurring in different diseases without much benefit In phthisis the recurring dyspnœa and orthopnœa are relieved during the period of inhalation only, returning in a few moments, and at times with increased violence

With so little experience, this drug must be administered with a certain degree of caution until its action is thoroughly understood, severe or persistent headache, nausea, vomiting, and vertigo acting as danger signals warning us to proceed with care — *New York Medical Journal,* March 13, 1886

Diagnosis of Cancer of the Uterus —Dr H Handford reports the following interesting case

M I , aged 24, was admitted into the Nottingham General Hospital under my care on April 7, 1885 Her family history was good Menstruation commenced at the age of 12, the flow lasted four days, and recurred every month She was married at 15, and had had two children, both of whom died before they were 6 month old Since then, she had had two miscarriages at about the third month, the last five years ago, since which time she had been regular She first noticed a fœtid vaginal discharge about six weeks before admission, and a little later saw Dr Truman at the Nottingham General Dispensary, who diagnosed cancer of the womb She never had any rash on the skin or falling out of the hair, and had no syphilitic eruption On vaginal examination, the cervix was found indurated, enlarged, ragged, and excavated so as to admit the index finger for about three fourths of an inch The uterus was somewhat restricted in movement, but the fundus was not enlarged The patient was also seen by Mr Wright, the senior surgeon, who confirmed the diagnosis of cancer The examination caused a little hæmorrhage I removed a small fragment of the growth, which, upon microscopic examination, was found to consist chiefly of large round cells, with a single large nucleus, but no flat or irregularly shaped cells The tissue was pervaded by the mycelium of a filamentous fungus (one of the hyphomycetes)

The patient left the hospital, and died eighteen weeks later, six month from the first symptoms No *post mortem* examination was made

The diagnosis was between cancer, sarcoma, and syphilis The ravages of the latter may be very extensive, but are stated to be limited to primary ulcers taking on a phagedænic character There was no evidence of syphilis in this case Sarcoma is said almost invariably to take its origin from the lining membrane of the body of the uterus, and not to commence in the cervix The microscopic examination of the portion removed did not suffice to determine the exact nature of the growth The fragment was necessarily small, was infiltrated with inflammatory materials, and consisted in large part of vascular granulations These latter cover the surface of ulcerating new growths, are an important source of the hæmorrhage, and, in many cases, differ very little in structure from healthy granulation tissue, though, in others, "cell-nests," or other characteristic structures, may be found For these reasons, I have come to the conclusion, after many trials, that negative results of the microscopic examination of scrapings or small fragments by no means disprove the malignant nature of the growth —*British Medical Journal,* March 20, 1886

The Functions of the Corpus Striatum — Herrn Baginsky and Curt Lehmann brought before the Physiological Society of Berlin, at the meeting on November 13, 1885, the results of their researches on the functions of the corpus striatum. They remark that as these organs lie deeply embedded in the brain they cannot be reached without considerable damage being inflicted on other parts, and they took pains to adopt a method which should minimise this injury. They found the plan which gave the most exact and uniform results was to plunge a fine glass tube into the corpus striatum and place the other extremity of the tube in connection with an exhausting syringe, by which the substance of the corpus striatum could be sucked out. The experiments were made on rabbits. If that part which projects into the ventricle were removed, the phenomena presented were that the fore and hind limbs of the opposite side were extended if the animal were previously in the sitting position. The extremities, and especially the anterior limbs, could easily be placed in anomalous positions, in which they remained till a stronger stimulus was applied. The movement of the extremities offered a certain resistance to the hand of the operator, which was greater than that of the opposite side. No motor defect was observed when the animal ran or made other voluntary movements. The temperature of the body remained normal, or only rose slightly and at a late period. The animal showed great excitability and much tendency to fear upon various sense impressions, making energetic efforts to escape by jumping from side to side. When the brain substance was removed down to the corpus striatum, without injury to that body, the same symptoms were observed, except that the rise of temperature was more common and greater. The authors of the memoir therefore arrive at the conclusion that the functions of the corpora striata do not differ materially from those of the superjacent brain substance.—*Lancet*, March 13, 1886.

METHOD OF TREATING FRACTURED CLAVICLE.—At the meeting of the Manchester Medical Society, on February 17, MR. C. E. RICHMOND demonstrated an easy method of treating this injury. The position adopted was similar to the French one, the palm of the hand of the injured side being laid flat on the chest. The best position for adapting the ends of the fragments was first ascertained by abducting the elbow from or approximating it to the sternum. A piece of broad strapping was passed round both arm and body, to fix it in the required position. A piece of calico, twelve inches broad (more in a big adult), and in length sufficient to go twice round the body, was torn longitudinally, so as to make a four tailed bandage, leaving about the middle eighteen inches untorn. This centre part was then grooved round the elbow, and the two lengths of the band (a), that lay next the body, were taken one up in front of the chest, over the flat hand, and the other up behind. These were then knotted together behind the sound shoulder, the other ends being meanwhile held out of the way. The other two lengths (b) were taken round the arm and body in front and behind, and also knotted behind and below the sound shoulder. The (a) ends were then brought down, one in front and one behind, and knotted betwixt the fixed elbow and the body, and then cut off short. The (b) ends were then again brought round the body over everything, and finally knotted in the hollow above the fixed elbow. Wadding was then inserted under the knots to prevent them from galling, and the hand against the chest was secured to the length of bandage, passing over it by means of a strip of calico passed round both. The advantages claimed were these: 1. There was no necessity for special apparatus; 2. The arm was fixed in the most favorable position; 3. The fixing was permanent. The method had been used in numerous cases with the best results.—*British Medical Journal*, March 13, 1886.

UNSTRIATED MUSCLE IN THE KIDNEYS.—The presence of a few scattered smooth muscular fibres in the kidneys has been noticed by several observers, and especially by Henle and Eberth, but DR. JARDET, of Vichy, has, in a short memoir contributed to the *Archives de Physiologie* of February 15, shown that there is a regular system of such fibres. Most of the text books state that a layer of smooth muscular fibres is present in the pelvis and calyces, the origin of which is referred to the double muscular layer of the walls of the ureter. Henle describes a special muscular annulus, composed of longitudinal and circular fibres around each papilla, lying just beneath the membrana propria. The longitudinal layer ceases at the plane of the floor of the pelvis; the circular layer may be traced some distance into the renal substance. The function of these fibres is to drive the urine forwards from the papilla into the pelvis. Eberth found, in man, a plexus of unstriated muscular fibres with large meshes on the surface of the kidney. Some of these fibres dip into the cortical substance of the kidney. The system of fibres described by Dr. Jardet were first noticed by him in pathological specimens, but were afterwards found to be present in the normal kidney. The situation, when they came clearly into view, was in transverse and verticle sections of the pyramids of Malpighi. They occupied the perivascular conjunctival sheath of the vessels, and never extended far amongst the renal tubuli. The fibres are grouped into small fasciculi, which spring from the pelvis and run parallel to the larger arteries and veins, but do not constitute a complete sheath to any vessel. They become hypertrophied in lithiasis, in hydronephrosis, and in all chronic inflammations of the kidney.—*Lancet*, March 13, 1886.

STRYCHNINE IN POST PARTUM HÆMORRHAGE.—In a note on this subject MR. F. H. V. GROSHOLZ says: Though I have not made any trial of a course of strychnine for pregnant women, to prevent the occurrence of hæmorrhage in labor, I have for the past ten years been constantly in the habit of administering it to arrest *post partum* hæmorrhage. My favorite combination to produce regular uterine contraction in these cases is a mixture containing fifteen minims of tincture of nux vomica, fifteen minims of tincture of opium, and half a drachm of ammoniated tincture of ergot. I have almost invariably had most satisfactory results with this dose. Nux vomica, through its alkaloid strychnine, has the direct and almost immediate effect of producing muscular contraction—especially strong in paralyzed parts—and also of retarding the circulation; nor is it improbable that the exaltation of the nervous system produced by its administration renders the action of the ergot more prompt and effectual. The object I had in view in adding the opium was mainly to prevent irregular or spasmodic contraction of the uterus, and also to allay the excitement frequently present in these cases. I have found the preparation of ergot here mentioned particularly reliable, and its stimulant effect is of decided advantage. In abortions and miscarriages, I have also had satisfactory results from the administration of this mixture, given frequently and in smaller doses. In future cases of unknown hæmorrhage tendency, I intend to try the effect of a course of strychnine, and expect that benefit will be derived from this anticipatory treatment.—*British Medical Journal*, March 13, 1886.

BELLADONNA INHALATION IN ACUTE BRONCHITIS.—MR. N. E. DAVIES says in regard to this subject: In acute bronchitis, I believe the dyspnœa is caused more by the contraction of the muscular tissue of the air cells due to the irritation caused by the bronchial inflammation, than by the viscid mucus secreted; and, acting on this belief in a case I had occasion to treat a few days ago, where the dyspnœa seemed likely to terminate life, I gave a grain of extract of belladonna in half an ounce of water, by means of a Dr. Seigel's inhaler. After the patient had inhaled this solution for a few minutes, the breathing became quiet and easy, and before the half ounce was exhausted, the patient was asleep. By repeating this remedy every few hours, with a stimulating system of treatment by the mouth, the patient, an old lady aged 75, soon passed the dangerous stage, and is now recovering.

I have often used this method of treatment in asthma with magical effect, and can strongly recommend its trial in the early state of acute bronchitis, as I have found it marvellously successful. It has the advantage of the ordinary bronchitis kettle, that it moistens the air of the sick-room, and administers a powerful remedy at the same time.—*British Medical Journal*, March 20, 1886.

EXPERIMENTAL AORTIC REGURGITATION.—By lacerating the aortic valves by the aid of instruments passed into the aorta through the carotid artery, M. FRANÇOIS FRANCK has been able to study the immediate and remote effects of this experimental form of aortic regurgitation. In some cases death supervened rapidly, especially when the heart was diseased previously. If the animal survived, the arterial tension, at first lowered, mounts again, and the heart becomes hypertrophied and its vascular activity is increased. According to M. Franck the excessive work of the heart is not to be solely attributed to the aortic reflex, but also to an irritation of the sigmoid region, on the ground that slight lesions or a superficial irritation of this region give rise to a similar hypertrophy. He also explains the danger of syncope of cases of aortic incompetence by the excessive and prolonged distension of the cardiac cavities, as well as by the depression of the arterial tension of the brain.—*Lancet*, March 6, 1886.

THE DIGESTION OF MILK.—DR. M. REICHMANN draws the following conclusions from a number of elaborate experiments as to the digestibility of milk in the human stomach (*Deutsche Med. Zeitung*, No. 82, 1885):

1. Boiled milk leaves the healthy stomach more rapidly than an equal quantity of unboiled milk.
2. The digestion of boiled milk is more rapidly accomplished than that of unboiled milk.
3. The coagulation of unboiled milk in the stomach is complete in five minutes.
4. The coagulation is not caused by the acid of the gastric juice, but by the influence of a special ferment (milk curdling ferment).
5. The acidity of the gastric juice is at first due almost solely to lactic acid, and, later in the process of digestion, to the presence of hydrochloric acid.
6. Hydrochloric acid first appears in perceptible amount forty five minutes after the ingestion of half a pint of milk.
7. For the first hour and a quarter after the ingestion of milk the acidity gradually increases, and then decreases, until the milk has entirely left the stomach.
8. The curds of casein in digestion of boiled milk are much softer than in the case of uncooked milk.—*Therapeutic Gazette*, March 15, 1886.

THE URINE IN PUERPERAL ECLAMPSIA.—M. DOLERIS has found that some specimens of the urine of patients with puerperal eclampsia give, on drying, crystals whose composition is at present undetermined, but which are slightly soluble in alcohol and soluble in acidulated water, and a somewhat concentrated solution of which injected into animals killed a rat and three sparrows, while comparative experiments made with a portion of solution containing no crystals produced no effect. M. Doleris found a normal amount of urea in the blood of two patients dead of the disease, but an increased amount in that of two others who were cured. In one case only were soluble and toxic ptomaines met with. He believes that puerperal eclampsia is of an infectious nature, for it is not only the kidney which is affected but other organs, the liver in particular presenting characters more or less allied to those noted in acute yellow atrophy.—*Lancet*, March 13, 1886.

BORACIC ACID IN DIABETES MELLITUS.—MR. F. A. MONCKTON reports in the *Australasian Gazette* (October, 1885) a case of a boy, aged 14, suffering from diabetes mellitus, with all the symptoms in an aggravated form, who was apparently cured by the use of boracic acid in 7 grain doses three times daily. At first there were no stringent dietary regulations, and even in the later part of the treatment only sugar, potatoes, and oatmeal were forbidden. Bread was eaten at the meals in the ordinary way. He gradually gained in weight, his health improved, and the sugar disappeared from the urine.—*Therapeutic Gazette*, January 15, 1886.

DIAPHRAGMATIC PLEURISY.

In the *American Journal of the Medical Sciences*, for April, 1886, DR. FRANK DONALDSON, JR., of Baltimore, gives a most interesting study of this rare affection. As is often the case when we come to look up the literature of some medical subject, we find that this affection was very accurately described by Galen, at least in so far as the peculiar character of the respiration and the retraction of the hypochondriac region are concerned, though he supposed that the seat of the affection was in the muscular structure and not in the serous covering. The disease was mentioned by several writers in the seventeenth and eighteenth centuries, but in an obscure manner, and it remained for Andral to publish, in 1823, the first definite observations of the affection, under its proper name diaphragmatic pleurisy. His paper was published in the *Archives de Medecine*, and in the following year, in his "Clinique Médicale," he gives a record of five cases. Thirty years after the appearance of Andral's paper Guéneau de Mussy published an elaborate monograph on the subject, in the same journal in which Andral's first paper had appeared.

Dr. Donaldson's case, on which his paper is based, was that of a man of about 40 years of age. He had been sick for nine weeks, the illness having begun with a chill "followed by an intense pain referred to the lower intercostal region, more particularly on the right side, with great and increasing difficulty of respiration. He had been, almost from the first, unable to lie down, sitting always with the body bent forward, and his hands pressed to the side to prevent any extra motion." There was an incessant dry cough, with dyspnœa and anxiety of countenance. The abdomen was retracted, the diaphragm almost immobile, and the respiration almost entirely costal. There was some dulness around the lower part of the chest, especially posteriorly on the right side. Pleural friction sounds were heard only on the left side. On the right side the inflammation had extended to the lung structure and set up a localized pneumonia. Anteriorly and posteriorly were points painful on pressure. The diagnosis was diaphragmatic pleurisy of tubercular origin, with slight effusion on the right side. The patient rapidly grew worse, the pneumonia was not resolved, and the lung began to break down. The patient died, but the record does not state at what time after the commencement of the disease.

Besides the serious and more rare forms of diaphragmatic pleurisy, there is a form called acute benign, first written of by Bucquoy, in his "Leçons Cliniques" in 1873. It always tends to recovery, and seems to be a distinct form of diaphragmatic pleurisy. Hermil, Bouchut, Monod, Robert and Fiessinger agree with Bucquoy, and report respectively (except Hermil) 3, 1, 1, and 9 cases, all ending in recovery. Its onset, with chill, pain in the side, and fever, is similar to ordinary pleurisy, but the painful spots and radiating pains, with tender and retracted abdomen, show that the diaphragmatic pleura is affected. It is unilateral until the third day, and then extends to the opposite side, though the invasion of the second side is not accompanied by great pain, and all the symptoms are less severe than when the first side is affected. It is a rather singular fact that the pleurisy disappears first from the second side, and the extension of the inflammation seems to lessen the symptoms. The effusion rises to a higher level on the second side, though the symptoms are here less marked. On the first side there is usually some retraction of the base of the lung on account of the fluid between it and the diaphragm. On account of the retractility of the lung, and the drawing up of the fluid with it, there may be signs of extensive pleuritic effusion, and an erroneous diagnosis is possible. This effusion usually disappears without surgical interference, and the cases result in cure within two or four weeks.

Andral, de Mussy and others think that diaphragmatic pleurisy is not so uncommon as is generally supposed. The number of cases on record is somewhat less than one hundred, but the apparent rarity may be due to errors in diagnosis and failure to record cases when seen. Though the onset is variable, the affection is usually ushered in by a chill of greater or less violence, followed by fever and sweating When secondary pleurisy occurs in the course of acute or chronic disease it is marked by an increase in the fever, or a second chill, but the pain and other characteristic symptoms attract attention chiefly "Intense pain in the side and constriction of the lower part of the chest, soon follow the chill The pains of diaphragmatic pleurisy are characteristic, and are to be referred to the terminal filaments of the phrenic nerve," what Hermil calls *douleurs par propagation* Many of the peculiar symptoms found in connection with the affection are explained by a reference to the anatomy and distribution of the phrenic nerve The pains extend over a large surface—"over the whole hypochondriac region and over both flanks to the inferior dorsal region behind, following the line of the costal insertions of the diaphragm, and often along the border of the sternum and under the lower insertion of the sterno cleido-mastoid muscle, and over the shoulder and neck" They may be spontaneous, but are always provoked by pressure, increased respiratory movements, hiccough, vomiting, etc The favorite seats of pain, according to de Mussy, are over the epigastrium, at the points of insertion of the diaphragm, in the eleventh interspace behind, near the spine, along the course of the phrenic nerve, and at the *bouton diaphragmatique*, a point one or two fingers'-breadth from the middle line, on a level with the tenth rib, or at the intersection of a line drawn from the osseous part of the tenth rib and one drawn along the border of the sternum The pain is always very great at this point, and is due, according to him, to the greater play of the rib, and the consequent friction against the inflamed nerve The pain along the course of the phrenic nerve is rarely spontaneous, but is always evoked by pressure, especially where the nerve runs under the sterno mastoid muscle

The *douleurs par propagation* run along the sides as far as the iliac fossæ in some cases, though they are usually more intense in upper part of the body, and are sometimes felt with great intensity in the muscles having nervous connections with the cervical and brachial plexuses As regards the pain felt over the liver and spleen it is difficult to say whether it is due to pressure of those organs on the inflamed muscle, as Dr Donaldson thinks, or to a local peritonitis from extension of inflammation Pain is more often present in the hypochondriac region than in any other locality in this affection The attitude of a person suffering with this disease is very characteristic, and is well shown in the case recorded The symptoms which are most distinctive and prominent are the frequency and shallowness of the respirations, respiration is entirely costal, and confined to the upper part of the chest, and in a case reported by de Mussy it was unilateral The number of respirations is enormously increased, Hayden and Graves reporting cases in which the number was 80 or 100 When effusion takes place in diaphragmatic pleurisy there is, according to Chaffaud and de Mussy, a lowering of the twelfth rib, its anterior end being lower than that of its fellow on the opposite side Hiccough, nausea and vomiting are often present, as might be supposed Delirium, which at one time was supposed to be diagnostic, is thought by de Mussy to be more frequent than in costo pulmonary pleurisy The affection is to be diagnosticated from rheumatism of the diaphragm, inflammation of the muscular structure and neuralgia of the diaphragm, costo parietal pleurisy, pericarditis, hepatitis, and circumscribed peritonitis, but it seems that proper care should prevent any error in diagnosis unless the disease be complicated with some one of these affections

CHRONIC TEA POISONING

At various times during the past few years medical men, chiefly in England, have called attention to the deleterious effects of tea upon those who partake too freely of this beverage But though some attention has been called to the subject very little has been written that is at all definite, in the way of substantiating assertions by clinical proof The paper on "Chronic Tea-Poisoning" read by Dr William N Bullard before the Suffolk District Medical Society on March 10, in which he gives a record of five cases may therefore be regarded as a valuable contribution to a comparatively obscure subject

In his paper Dr Bullard deals only with cases of subacute and chronic tea poisoning, leaving out of account all acute cases and those of professional tea-tasters These have already been fully written of by Morton, in a paper on tea tasters, based on five cases, in which he gives the symptoms of "continued and immoderate use of tea" as headache, ringing in the ears, tremulousness, nervousness, exhaustion of mind and body, with disinclination to mental and physical exertion, increased and irregular action of the heart, and dyspepsia It will be seen that these symptoms correspond very closely to those of chronic tea poisoning Dr Bullard's statistics are based on 163 cases of tea-drinkers, and he also examined, for the purpose of differentation, 158 cases in which symptoms of tea-poisoning occurred, but in which he was not inclined to attribute the symptoms to the abuse of tea. In analyzing his cases he follows the order of symptoms given by Morton, and considers the frequency of the different symptoms, in order to see what combination of these may be considered as characteristic of tea-poisoning Headache occurred in 30 per cent of the cases, hemicrania in 11 per cent In the cases in which the headache was bilateral it was situated generally in the forehead and temples "Ringing in the ears" was not frequent It was noted in but three cases, in two of which it was due to disease of the ear, while in the third case it accompanied a congestive headache supposed to have been due to exposure to a hot sun

We may very properly classify four of the symptoms under the general head of nervous phenomena Tremulous, according to Dr Bullard, is not uncommon, and it probably occurred in many cases in which its existence was not noticed or specified In other cases it was probably given as "nervousness" Tremor was noted in six cases, "but in only one of these does is seem fairly attributable to the tea," and he concludes that tremor is not an ordinary symptom of chronic tea poisoning "Nervousness" was prominently noticeable in 16 per cent of the cases, its total absence in one case "Slight degrees of nervousness probably exist in nearly all these patients, but we cannot therefore conclude that it is the direct result of tea" In many cases it is doubtless due to the digestive troubles As regards the symptom "exhaustion of mind and body, with disinclination to physical exertion," Dr Bullard says that it "is of too indefinite a character to be susceptible of accurate determination in the class of cases with which we have to deal Moreover, its liability to occur from other causes renders it impossible to determine how far it is due to tea" We have noticed this symptom prominently in tea tasters, however In the cases examined general weakness was mentioned in 8 per cent Increased and irregular action of the heart does not appear to be a necessary symptom of chronic tea poisoning Palpitation, which was present in almost all severe cases, occurred in 49 per cent, and irregularity of the heart in six additional cases

The symptom dyspepsia in those who use tea immoderately seems to have been more frequently noticed than any other by foreign writers, and Dr Bullard says that "the occurrence of gastric or intestinal symptoms with chronic tea-poisoning is almost universal," but that in many cases these do not assume a very prominent form He has noted those cases only in which there was "a distinct sense of oppression or fulness in the epigastrium after eating" Of these there were seventy-five cases, or 46 per cent Pain in the epigastrium occurred in 9 per cent Vomiting occurred in 17 per cent (twenty-eight cases), and nausea in 20 per cent In thirteen cases the vomiting was combined with nausea, in twenty two cases it was noted under dyspepsia. Nausea was reported alone in five cases, in three of which it occurred with headaches, in one there was trigeminal neuralgia, and in one it was probably due to the use of tobacco Pain in the left side, or in the cardiac region, which is a frequent symptom in women, and probably due generally to the gastric condition, occurred in 21 per cent of the cases It is surprising to note that serious intestinal disturbances, and especially constipation, do not, according to Dr Bullard's account, occur very frequently in the cases under consideration Loss of appetite occurs in a greater percentage of cases (61 per cent) than any other symptom Dyspnœa was present in twenty-three cases, "but seems usually to be secondary to anæmia or cardiac weakness" In two cases it was due to pulmonary disease, and in nineteen was accompanied by palpitation It is somewhat surprising that anæmia was present in only 18 per cent of the cases We may therefore put the comparative frequency of symptoms in chronic tea-poisoning as follows anorexia 61 per cent, dyspepsia and pain in the epigastrium 52, palpitation 49, constipation 47, nervous symptoms 42, headache 30, pain in left side 21, nausea 20, vomiting 17 "All these symptoms are common in many other diseases, but it is the special combination which exists here, and above all the predominance of the nervous group, which enables us to form our diagnosis It is evident that there exists many cases of this affection in which no diagnosis could be arrived at from the symptoms alone without the history, but I firmly believe that in the majority of the cases, a presumption in favor of this affection is justifiable from the sole evidence of the symptoms"

The first evidence of chronic tea-poisoning is a gradually increasing difficulty of digestion, followed by general restlessness and excitability of the nervous system, by disinclination for food and headaches Constipation is present in almost one half the cases "Palpitation, which has previously been slight, now becomes distressing, and is not infrequently accompanied by dyspnœa" Up to this point the patient may declare that her health is good, but in the more severe cases the symptoms now become more pronounced, and usually point to digestive troubles or hysteria, or both "Whenever a marked gastralgia exists without evidence of organic disease, wherever we find frequent vomiting apparently unaffected by food and unaccompanied by gastric catarrh, in other words, wherever we find evidence of a true gastro-neurosis, or if increased excitability of the gastric nerves greater than could ordinarily be accounted for by by the condition of the stomach, whether dyspepsia be present or not, if the agency of alcohol can be eliminated, we should always suspect tea-poisoning. We have at present no evidence in regard to the condition of the blood vessels in this affection and it is reasonable to suppose that no great variation from the normal will be found, inasmuch as the trouble is so chronic and in many cases so slight. Whether or not any increase exists in the excitability of the vaso-motor nerves under these conditions would be an interesting subject for investigation.

It is of special importance to remark that the affections of the nervous system due to chronic tea poisoning are, so far as my observation show, *always functional*. Where organic symptoms exist they are not connected with tea.

The average amount of tea taken by those who showed symptoms of poisoning was 4.8 cups *per diem*. This, however, cannot be taken as a standard for making a diagnosis in any given case. The age and physical condition of the patient are very important considerations. Youth, weakness of any kind, and anæmia, naturally render the system more susceptible to any toxic influence, "and hence we find that even those adults who have for years been accustomed to take a moderate amount of tea without evil effects, if for any reason they become anæmic, if their strength be exhausted by excessive work or in other ways, immediately begin to show toxic symptoms, although the amount of tea ingested has not increased. This is well shown in cases of chlorosis and is very common among factory operatives and seamstresses. We desire to lay special stress on this fact, which is one cause of the non-recognition of the toxic agency of tea by the patient. That deprivation of fresh air and want of sufficient food should cause the same result is only to be expected, not only because in themselves they tend directly to produce weakness and anæmia, but also because the toxic products are *not so readily eliminated*. It is for the same reason that more tea can be drunk without evil effect by persons when working or taking exercise than could be taken by the same person when idle or at rest."

PROPOSED NATIONAL BUREAU OF PUBLIC HEALTH.

Under this head in another department of THE JOURNAL will be found a copy of the Bill recently introduced into the House of Representatives by Dr. Robert T. Davis, member from Massachusetts, "to prevent the introduction of contagious and infectious diseases, and to establish a Bureau of Public Health," which was referred to the Committee on Commerce, subsequently reported by the Committee with some amendments, which are included in the present copy, and it was referred to the Committee of the whole House on the State of the Union.

It will be seen that the Bill simply provides for the establishment in the Department of the Interior of a Bureau of Public Health, under the management of a Commissioner of Health with an annual salary of $4,500, with all the necessary powers and duties to secure the establishment of an efficient and permanent National Bureau of Public Health, to take the place of the old National Board of Health, and *relieve the Marine Hospital Service from further* duties in that direction.

The provisions of the Bill are simple and not likely to bring the Bureau in collision with the State Boards of Health or sanitary regulations, and yet the powers conferred are sufficient for the establishment and maintenance of all such necessary measures as are calculated to prevent the importation of contagions and infections either by persons or goods, for the collection and publication of information concerning the prevalence of epidemic and infectious diseases in all foreign countries with which we have commercial relations, and for prosecuting of original scientific investigations concerning the nature, origin, and prevention of contagious and epidemic diseases both in the United States and in foreign countries. The Commissioner is also authorized to employ such assistants, clerks and scientific experts as may be necessary, with the consent of the Secretary of the Interior.

The introduction of this Bill is the first move we have seen relating to health or sanitary regulations by the general government, which was in the right direction and founded on correct principles. All propositions hitherto made to establish National Boards of Health consisting of several members, representing different sections of the country and somewhat different interests, have two radical defects. First, they are too cumbrous, it being necessary that their most important duties should be performed while in session, and second, they inevitably contain more or less elements of discord. A permanent government Bureau under an intelligent Commissioner, with all necessary assistants, avoids both these evils and affords the best prospect for promptness and efficiency of action. We hope, therefore, that the Bill will speedily pass both Houses of Congress and become a law.

IMPORTANT NOTICE

We have received from the Treasurer of the American Medical Association, the names of one hundred and fifty three members of the Association who have not paid their annual membership dues since 1883 Consequently their names have been suspended from the mail list of The Journal, and will remain so until we are notified by the Treasurer that their dues have been paid Any of them who choose to pay their arrearages to the Treasurer before June 30th, when the current volume closes, can have their files completed We have also received, from the same officer, the names of two hundred and one members who have not paid their dues for the current year, now nearing its close All members who attend the annual meetings of the Association are required to pay the membership fee in advance, before they can take a seat in the meeting, and it is manifestly unfair for those who do not attend the meetings to neglect the payment of their annual fees until the end of the year, or longer, and still be receiving The Journal the same as those who pay promptly As many of those who are still indebted for the current year may pay up at the coming meeting at St Louis, we have thought best not to suspend their names from our mail list until after that meeting But the Association should adopt a rule, or by law, making all annual dues from members payable before the 1st of July of each year, and in default, their names to be liable to suspension from the mail list of The Journal

INJUSTICE TO DR FANCOURT BARNES

In the April, 1886, number of the *American Journal of the Medical Sciences* is a review of the "System of Obstetric Medicine and Surgery" by Drs Robert and Fancourt Barnes The writer of the review says, page 522 "Unfortunately, there is a little matter relating to the publication by Fancourt Barnes of a German Medical Dictionary, which does not dispose the profession of this country kindly toward him That this little volume, published as his, was boldly copied from one the production of an American physician, is only too evident from the fact that the very errors of the one duly appear in the other" The reviewer gives the name of the American physician as George R Cut*l*er instead of Cutter! From this it seems that the reviewer is not familiar with Dr Cutter's book Dr Cutter's Dictionary contains about 13,000 words, and that of Dr Barnes about 22,000, from which it seems that he is not familiar with Barnes's book! How a book can be "boldly copied" from one only a little more than half as large does not appear All of the errors in Dr Cutter's Dictionary do not appear in Barnes's Dictionary, very many were corrected But the fact that the two books contain the *same* errors in many places proves nothing Dunglison's Medical Dictionary contains an error that is to be found in Cotgrave's French and and English Dictionary, published in 1660, and our large unabridged dictionaries contain propagated errors sufficient to convict the authors of plagiarism from any one of half a dozen lexicographers, if this be sufficient evidence for conviction Of these we need only cite Richardson's Dictionary, Todd's Johnson, Webster and Worcester As a matter of fact, too, Barnes's Dictionary contains errors in words that are not in Cutter's Dictionary at all, and other errors in words that are correctly given in Cutter

Great injustice in regard to this matter has been done Dr Barnes in this country, as this same fable was put in circulation when his book first appeared We can give the names of several German students, prominent physicians in this country, who believed it and would not get the book Some had never even seen it until their attention was called to it, but they knew the story, though it is far superior to Dr Cutter's Dictionary An importing firm in the East brought over a lot of about 500, and had sold a few when they received a note containing this charge They bought up the few copies that had been sold, so far as they could, and shipped the whole lot back to England without even making an investigation We have no quarrel with anyone in this matter, but make this statement in simple justice to one who is not in this country to defend himself E

SOCIETY PROCEEDINGS

OBSTETRICAL SOCIETY OF PHILADELPHIA

Stated Meeting, Thursday, March 4th, 1886

The President, B F Baer, M D, in the Chair

MENSTRUAL EPILEPSY

Dr Howard A Kelly exhibited recent specimens of tubal and ovarian disease, removed within the past two weeks The first specimens to which he called attention were removed from a patient 21 years of age who has suffered from an aggravated menstrual epilepsy from the very first appearance of the function There was no difficulty whatever in the removal through a small incision into which two fingers could just be slipped The whole operation, from beginning to complete closure, took but twenty-four minutes The right ovary was deformed by a very prominent nodule, about one and a half centimetres in diameter, which burst on removal, discharging a watery fluid, and was shown by its lining membrane to be the last corpus luteum

The second specimens were rare examples of *Hydrosalpinx, with Congenital Deficiency of Tubes and Broad Ligaments* In this case there was malformation of the distal ends of the tubes, broad ligaments and ovaries The left tube is as large as a bologna sausage It was brought into view with great difficulty after separating many light adhesions to the pelvic walls, while the isthmus is much enlarged and thickened, the great distension is at the involuted ampulla The operator was materially assisted in bringing this tube into view by upward pressure on the cervix by a hand in the vagina The fimbriated extremities were lost in a mass of vascular and fibrous tissue forming a broad ligament, and deep down in this were imbedded the somewhat hard, elongated, large ovaries It was utterly out of the question to attempt a removal of the ovaries, and any such operation would have been of a very desperate character, nor did he, Dr Kelly, regret this in the least, as he had planned his operation for *tubal* disease, to which he attributed all the patient's sufferings The right tube was as large as his middle finger and was also distended with watery fluid

The other specimen was a very large *Hæmato Salpinx* This tube, the left, about four inches long, burst as he was removing it, discharging four ounces of tarry blood It was very adherent, having several attachments to intestine and omentum The dilatation is here, too, seen to be at the ampulla, which extended far beyond the ovary back into the cul de-sac The ovary is embraced by the isthmus, and presents a curious appearance as it lies, about twice the normal size, imbedded in a sort of ball and socket manner below the isthmus Where it is laid open the tube is converted into one large sac

Dr Joseph Price remarked that the tube was so large that the uterus had been pushed aside by it Great care was required in its removal

Dr Chas Herman Thomas said that some time since he should not have recognized such a condition, but now he can, the result of experience in bimanual examination He would like to hear further on this point of diagnosis

Dr B F Baer thought it very unfortunate that the ovaries as well as the tubes could not have been removed in the case just reported by Dr Kelly, for their presence will probably result in the usual monthly congestion, and consequently the pain and other pelvic distress for the relief of which the operation was performed, may continue to exist There are several cases on record in which the tubes were removed and the ovaries allowed to remain, but the results have not been reported He could see no reason why this should be done unless the ovaries cannot be found, or some other insurmountable difficulty presents itself He fully believes in the advantages of prolonged and thorough palliative treatment in these cases Benefit usually follows, and sometimes cure, at least operation is rendered less difficult and more likely to be followed by recovery of the patient, both from the operation itself and the symptoms Certainly the application of remedies such as iodine to the fundus of the vagina and the interior of the uterus, with prolonged rest and general building up of the system, will have a strong influence in attenuating adhesions, promoting absorption of lymph and possibly, if not probably, in cure of the patient without operation

It should not not be forgotten that removal of the tubes and ovaries in these cases does not cure absolutely in every case He believes that we will be called upon in a few years by many of these cases which have been operated upon to relieve symptoms which still exist or have returned, and for the relief of which operation had been performed, just as we have been called upon from time to time and pestered by those old cases of chronic hypertrophy and retroflexion of the uterus with pelvic adhesions He has now under his care one of his own cases upon which he operated for the relief of symptoms, the result of disease of the tubes and ovaries with pelvic adhesions The patient made a good recovery and appeared to have been cured, but the symptoms have returned, and she is now complaining almost as much as before the operation She also has periodical attacks of metrorrhagia This, of course, is an unusual case He has another patient under his care, who was operated upon in a neighboring city by removal of the tubes and ovaries, and is treating her for the same symptoms of which she had complained before the operation He is an advocate of the operation in some cases, but he pleads for due deliberation and the exhaustion of careful palliative and preparatory measures before operation is resorted to Many cases will get well without operation Some will not be benefited if operation is performed, and there is some danger in laparotomy, although Tait has had such remarkable success

Dr Da Costa inquired if Dr Kelly had tried the benefits of rest and treatment before operating?

Dr Joseph Price said that the recurrence of symptoms seemed to indicate partial removal of the tubes and ovaries One of the fundamental rules of surgery is to seek for pus when it is probably present and in all cases to remove it if possible When the ligatures will cut through the tubal stump on account of its cheesy character, hæmorrhage may be prevented by the application of the cautery

Dr Kelly, in closing the discussion, said he did not in the least regret that the ovaries could not be removed, as he had operated for tubal disease, not for ovarian and he admired the zeal of Schrœder, who, instead of always removing the ovary, sometimes resected diseased portions In all the cases of tubal and ovarian disease upon which he had operated, months and years of careful treatment had been wasted, and now, where he diagnosticated pyosalpinx, the only delay he allowed was to put the patient in the best possible condition for operation Topical, external and internal, treatment is utterly futile, and never does more than secure temporary palliation

Dr Kelly's reliance regarding diagnosis lay entirely in a skilled bimanual examination, by which he always accurately mapped out all the peculiarities of the case before operation If there is rigidity and resistance it is necessary to etherize, but he has yet to see the case where the presumptive signs were those of tubal and lesser ovarian disease, where the structures could not be picked up between the two hands and outlined. He considers that this tact has been largely developed by persistently examining the condition of the appendages to the utmost possible extent as a routine practice in all cases which come under his notice. Introducing the finger as high as possible, by forcing the hand well under the pubic arch, and carrying the sensitive pulp up against the post fornix or either lateral fornix, and then playing up and down with the other hand pressing on the abdomen and creeping a quarter inch at a time, without ever fully relaxing, and letting structures in between roll through the two fingers, and in case of an ovary, running round its whole periphery, or of a tube tracing it up to the cornu uteri and down into the retro uterine pouch, where it generally terminates, give often most surprising results, and would doubtless, if fully carried out, change hundreds of diagnoses of leucorrhœa, endometritis and flexions with adhesions, to the far more serious ones of pyo- or hæmato salpinx.

Dr. Joseph Price exhibited some

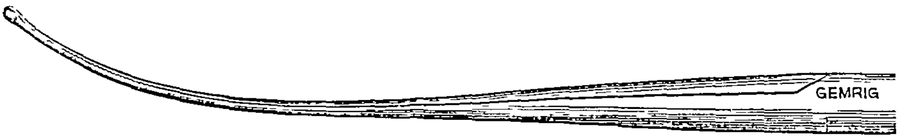
SPECIMENS OF PYO SALPINX

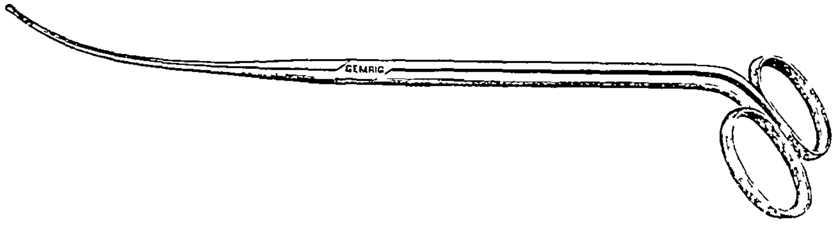
from two patients, and afterwards remarked that Tait and Keith have ended the dark period by showing us how to operate on the abdomen and pelvis without fear and with little risk. The wonderful advance in pelvic and abdominal surgery should be placed to their credit. He believes it is now universally admitted that they have reached the very acme of perfection. One surely must be a convert to Tait's law to contend with the great difficulties in pelvic surgery: "That in every case of disease in the abdomen or pelvis, in which the health is destroyed or life threatened, and in which the condition is not evidently due to malignant disease, an exploration of the cavity should be made." Standard works on ovariotomy dwell at great length on the subject of adhesions as the most important and difficult complication with which the operator has to contend. In short, in pelvic operations the risk and the difficulty will ever lie in the separation of organized inflammatory products. Adhesions, when old, between the pelvic viscera and diseased tubes, become degenerate and hence easily ruptured. In one case only have strong adhesions, deep in the pelvis, stayed his hand. The right tube and ovary adhered strongly to the sac and right side of the uterus, and the whole adherent mass was absolutely inseparable. Again, the rupture of pus tubes or cysts filled with inflammatory, septic or malignant elements, will be followed by serious symptoms. Operation becomes difficult when the ovaries and tubes, tightly distended with pus, and softened through pathological changes, cheesy in consistence, are matted together with the rectum and small intestines.

Dr. Charles Hermon Thomas exhibited a

UTERINE APPLICATOR AND DRESSING-FORCEPS COMBINED

This instrument, which is is specially adapted to making applications within the cavities of the neck and body of the uterus, but which is also available for making dressings and applications to the vagina and external surface of the cervix, has borne the test of two years' use. It is in forceps form, the blades are strong and resistent from the handles forward about two thirds of their length, when they narrow rapidly, so that taken together they become about equal in size to the ordinary uterine sound. This narrow portion, somewhat suggestive of the long beak of the angular ear forceps, is about three and a half inches in length, the tips being roughened on their opposed surfaces. It holds securely the smallest pledget of cotton, and by reason of the springy character of the beak will permit the locking of the handles when a full sized pledget or tampon is placed within its grasp. The point is slightly probed as an extra precaution when introduced to the uterine fundus, though a small cotton ball answers all needful purposes as a protective tip. I have usually employed the plain point on account of its occupying less space at the internal os uteri. The beak is curved to a shape corresponding very closely to that of Ellinger's dilator, and which has been found so generally well adapted to entering the uterus. This portion is electro plated with gold, when so ordered (a proceeding of moderate cost and to be commended) as a protective against the corrosive action of iodine, iodized phenol, and the like, which so rapidly destroy nickel plating and corrode pol-polished steel surfaces. The instrument was made under Dr. Thomas's directions by J. H. Gemrig & Son, of Philadelphia.





Some practical points of use may be mentioned Soiled or medicated cotton is easily removed with the use of one hand only by simply unlocking the handles and wiping the point in a crumpled paper, thus leaving the other hand free for other employment, and avoiding the trouble, the soiling of the fingers, and the whittling often involved when the wire applicator is used In its use there is immunity from the rasp action of the closely wrapped cotton of the wire applicator, and also a greatly increased carrying capacity of the cotton for medicated liquid Moreover, it will be found convenient and desirable to make use of the instrument as a uterine sound incidentally in certain instances In my own experience it has proved practicable as an applicator, one fully meeting the needs of most cases, while as a uterine dressing forceps for general use it has been found so satisfactory as to have superseded all other instruments of this class

Dr Baer said the instrument presented by Dr Thomas is a very ingenious one, and will doubtless serve a good purpose where the cervical canal is patulous, a greater quantity of the medicating agent used can be carried to the diseased surface than when the tightly wrapped cotton is used

Dr J F Wilson has nothing to add to what Dr Thomas has said He has used one for several months and can agree with Dr Thomas as to the ease of application and removal of soiled cotton

Dr Parish said that the forceps was valuable and would be much used As an applicator it will be very convenient A few years ago the sound and applications were too much used, but extremes either way are wrong Applications to the endometrium are sometimes needed

Dr H A Kelly said this is a very valuable instrument

Dr Parish exhibited a specimen of

OVARIAN TUMOR,

removed the previous day The symptoms had been very peculiar and the form of the abdomen was misleading, there being a deep groove across the hypogastric portion of the tumor Numerous adhesions gave great fixity These adhesions embraced the colon, parietes and bladder, and were old and dense Its rapid growth had raised a question of malignancy A great portion of the tumor was solid

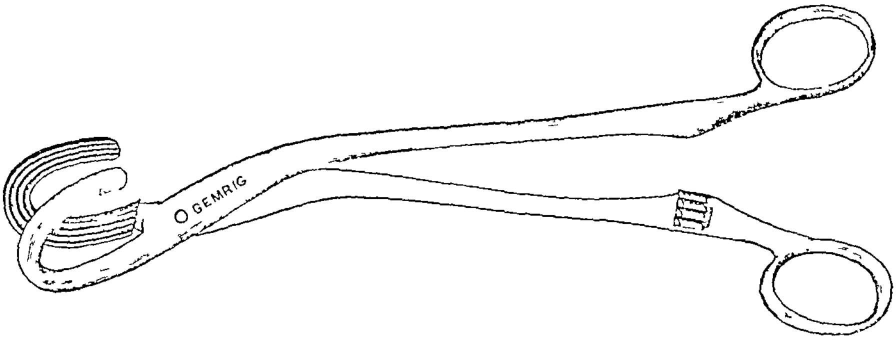
Dr Harris remarked that a microscopic examination of the tumor should be made There had been great difficulty in diagnosis as to the origin and character of the tumor A slight fluctuation could be detected in the lower portion under the use of an anæsthetic There had been no uterine symptoms, and menstruation had been regular The long fallopian tube crossed the tumor and made a deep constriction across its middle

Dr Baer did not think rapid growth a proof of malignancy He had seen five or six cases of very rapid development, one in three months contained a bucketful of fluid In none of these cases had there been any return or other sign of malignancy The presence of papillomatous growths within the cyst is no proof of malignancy

Dr Joseph Price exhibited a

FORCEPS

for the complete closure of the trocar puncture in ovariotomy



MEDICAL SOCIETY OF THE DISTRICT OF COLUMBIA

Stated Meeting, February 24, 1886

The President, C H A Kleinschmidt, M D, in the Chair

T E McArdle, M D, Secretary

Dr G S Palmer presented specimens of

ABSCESS OF THE CORPUS STRIATUM, AND ADHESION BETWEEN THE GALL BLADDER AND THE COLON

The case to which your attention has been called by the Secretary's cards for me to report this evening, presents some points of interest both in its history and in the appearance presented by the post-mortem examination, and may suggest questions and elicit discussions which will be interesting and useful This case also reminds us of the humiliating fact that we are yet sometimes obliged to depend upon an autopsy for a correct diagnosis of our case

The patient, Mrs ——, age 66, married and mother of three children, died in the early part of this month, and a post mortem examination was made by Dr D S Lamb five hours after death As a child and a young woman this patient enjoyed good health, but she belonged to a short-lived family, she being the oldest of ten brothers and sisters, all of whom died many years before she did Fourteen years ago she had a severe and protracted sickness caused principally by an acute inflammation in the right hypochondriac region. At the time, this inflammation seemed to pervade the duodenum and the pyloric orifice of the stomach. It evidently involved some portion of the peritoneum, as the severe pain, rapid pulse, tenderness and prostration plainly indicated.

Some light is shed upon this part of the case by the autopsy, which discloses a firm adhesion between the hepatic flexure of the colon and the fundus of the gall bladder, and an almost entire obliteration of that cyst; in fact, the gall bladder is reduced to the size of a small tube, and extends from the cystic duct to the fundus of the gall-bladder where it is adherent to the colon, where there has evidently been a free opening, so that that part of the bile which is usually held in reserve in the gall bladder has passed directly from the cystic duct through the opening into the colon.

The most plausible explanation which I can offer for this state of things is, that just prior to the sickness spoken of above, gall stones had accumulated in the gall bladder to such an extent, or of such irritating character, as to set up inflammation in that organ, and by contiguous sympathy to induce the same in the colon and cause adhesions between them, which was followed by an ulcerative opening in the walls of each, so that the gall stones and the bile passed freely into the bowel. This may account, in part at least, for the frequent attacks of jaundice which the patient had during the last fourteen years of her life. In the healthy or physiological state, bile is not found in the large intestine, and we know very well that the ascending and transverse colon are abundantly supplied with absorbent vessels so that the bile falling into the colon through this opening would be easily taken up and carried into the general circulation, and thus give rise to jaundice. About five years ago this patient, apparently from a severe mental shock, became much depressed; she lost her appetite, grew feeble in body, and at times was a little off in her mind. Tonics, stimulants, and tender care all failed to improve her, and travel was suggested. After a short absence among new scenes and new faces she returned much improved, but not quite well. She had now for nearly two years frequent attacks of jaundice, almost continuous dyspepsia, and some slight disturbance of the mental faculties; in fact, these symptoms continued with variations to the end of life.

About two years ago the mucous membrane of the mouth and pharynx took on an aphthous condition, which continued for a long time, and finally the surface of the tongue became ulcerated, and for more than a year that organ presented the appearance of raw beef. During this time there was not only a complete loss of appetite, but also a loathing of food and very imperfect digestion of the little food which passed into the stomach. Under the use of chalybeates, arsenic, mineral waters, bismuth, etc., and numerous mouth washes, these ulcers of the tongue healed and the papillæ and mucous surfaces appeared quite natural, but the sense of taste never returned. She could feel the food in her mouth but it had no natural taste; whether this loss of taste was caused by a morbid condition of the peripheral terminations of the gustatory nerves, or whether their deep seated origins were at fault, it was impossible to tell. About one year ago this patient's hair began to fall off, so that in a few months ever spear had disappeared from the scalp; the eyebrows and eyelashes fell off also and most of the hair from the other parts of the body, thus presenting a typical case of alopecia universalis. No disease of the hair follicles could be detected by the naked eye; the hairs seemed to drop out for want of nourishment, the follicles closed up and the scalp became smooth and shiny and remained so till death. A remarkable paleness pervaded the whole body at this time, giving unmistakable evidence of anæmia. About five months ago she began to lose the use of her upper and lower extremities, so that she was in a very short time unable to stand upon her feet or to feed herself with her hands. A partial paralysis plainly existed. After a continued use of electricity for three or four weeks she regained the use of her muscles so that she played a simple tune on the piano. This paralysis was more marked on the right side of the body. The small softening found in the left corpus striatum may have been the cause of this paralytic condition. This patient had finally some attacks of bilious vomiting, followed by great prostration; after one of these she went into a comatose condition and died of exhaustion caused by anæmia, which was found at the autopsy to depend upon the atheromatous condition of the large arteries supplying the brain and other parts of the body.

It is remarkable that during all these last years of her sickness her pulse was regular, soft and natural; only a short time before death did it become small and more rapid; and the heart, notwithstanding the mitral valve was loaded with atheromatous deposit, gave no abnormal sounds. I know of no set of symptoms which would enable the most astute diagnostician to tell what he was dealing with in a case like this.

The treatment of this case has been principally to mitigate symptoms, and it is a pleasant reflection to know that had we had a full knowledge of the pathological conditions we could not have done better.

Dr. D. S. Lamb presented a specimen of

EXTRA UTERING PREGNANCY.

Mulatto woman, age 20, was admitted to Freedman's Hospital, D. C., September 25, 1885, with uterine hæmorrhage and acute peritonitis. After convalescense she went out of her own accord. Was readmitted November 27. Died February 19, 1886. A tumor was recognized above and to left of hypogastrium; this partially disappeared quite suddenly some days before death. She denied pregnancy.

Necroscopy by Dr. D. S. Lamb. Body well nourished; bloody fluid in pericardium; heart flabby; old firm adhesions of left lung everywhere; right pleuræ contained about a pint of dirty, bloody, purulent liquid; lung collapsed; abdomen much distended with gases; contained some bloody liquid; uterus enlarged; left fallopian tube converted into a large sac with thick walls, placenta in left anterior portion, this sac had formed old cord like adhesions to intestines, and also recent ones, it had ruptured posteriorly, edges very ragged, fœtus lying in abdominal cavity above and to left of uterus The fœtus, ragged edge of sac, placenta and cord, liver, spleen and kidneys were far advanced in decomposition

DR J F HARTIGAN presented a specimen of

GUN SHOT WOUND OF THE HEART

J C , æt 14, was shot accidentally on the evening of February 20, 1886 Deceased was going up stairs when the revolver was discharged from the landing above Immediately he whirled about, fled through the front room about twenty feet, and fell down the porch steps exhausted He lived about four minutes

The necropsy showed the ball to have entered the left border of the sternum, on a line with the cartilage of third rib, it then penetrated about the middle of right ventricle of heart, and, passing diagonally downwards, made its exit in the posterior aspect of left ventricle, near the apex, the anterior wound of the organ was an inch in length, the posterior an inch and three quarters, presenting a chasm like appearance from tissue destruction Having wounded in succession the lung, liver and pancreas, the ball traversed the psoas muscle, fractured the crest of the ileum, and finally lodged in the glutens maximus, under the skin

The case is interesting in two aspects first, on account of the course of the missile, although this may be accounted for in a measure by the relative position of the perpetrator and victim, and secondly, the length of time deceased lived, and the extra ordinary physical exertion following an injury of the heart such as has been described

DR J FORD THOMPSON presented

AN OVARIAN CYST

from a patient on whom he had operated at the Garfield Hospital The patient is a Scotch woman 64 years old, the mother of seven children Menstruation ceased ten years ago Up to within the past eighteen months she enjoyed good health At that time œdema of the left foot and leg was noticed, and soon after the abdomen became slightly enlarged During the past three months she has been a good deal confined to her bed and has suffered much from nausea and vomiting

This case is worthy of record on account of the very slight degree of constitutional disturbance which followed the operation The operation was performed in the usual manner, except that in closing the wound, after ligating the pedicle and dropping it into the peritoneal cavity, three sets of sutures were employed First, the peritoneum was closed by a continuous suture of catgut, the linea alba brought together by a second line of catgut sutures, and finally the external integument was approximated by interrupted silver and silk-worm gut sutures The advantage of this mode of procedure is very obvious The sutured abscesses, so called, are avoided, or at all events, should abscess occur about the abdominal sutures, the entrance of pus into the abdominal cavity is prevented by the continuous suturing of the peritoneal surfaces This mode of suturing the abdominal opening also renders the patient less liable to ventral hernia from imperfect coaptation of the parts The patient was discharged cured in about a fortnight

---

Stated Meeting, March 3, 1886

DR D S LAMB (through Dr Smith) presented

A HEART WEIGHING THIRTY EIGHT OUNCES

It was removed from a tall, robust, dark mulatto man, who died February 20, 1886, of acute pericardial effusion Aortic valve somewhat thickened, left ventricle much dilated Aorta and branches somewhat atheromatous Other viscera normal Kidneys weighed thirteen ounces each

Necropsy made March 1, 1886, by Dr D S Lamb for Dr T C Smith, on a mulatto woman about 45 years of age Body somewhat emaciated, abdomen protuberant Lungs showed firm old pleuritic adhesions and were full of cheesy tubercles and vomicæ Heart appeared normal, not opened Liver firm, anæmic, firm old adhesions everywhere stomach and intestines generally collapsed and firmly adherent to adjoining viscera, abdominal wall, and tumor Kidneys showed hydronephrosis, especially marked in left, ureters dilated Uterus elongated, cavity five inches long, what appeared to be the body was of normal width, what appeared to be the fundus was enlarged by a large fibroid growth with thick capsule, in some places calcareous, its peritoneal covering thick, rough, whitish, dull looking, and covered with patches of old lymph and many thick vascular bands, posterior and lower portion, left side, showed a large irregular cavity with calcareous wall and cheesy contents, the adhesions were most marked around this cavity There were several small isolated tumors in left side of body of uterus (?) All the supplying vessels enlarged Ovaries and Fallopian tubes not identified Weight of uterus with tumor, sixteen pounds

THE DRUG ALVELOZ

DR J B HAMILTON recalled to the Society the fact that some months ago he had introduced at one of the meetings, a man who had been suffering from a lupoid ulcer of the face This patient had been treated with applications of alveloz, a drug which is indigenous to Brazil, and is there said to have a beneficial effect upon cancers, especially those of the epithelial variety When presented to the Society the man was to all appearances practically well, the ulcer having cicatrized Four months afterwards the sore reappeared At that time the specimen of the drug which Dr Hamilton had obtained from the State Department gave out, and he was unable to procure anything like it in the market Indeed, no two specimens purchased by him resembled each other None of them have had any effect With the specimen obtained directly from Brazil, through the Department of State, Dr Hamilton treated an epithelioma involving a part of the cheek, nose, and eye Pain and hæmorrhage were almost constant symptoms A few applications checked the hæmorrhage and relieved the pain The character of the granulations was entirely changed, and cicatrization was going on well The American Surgical Association being in session here at the time, he showed the case to several of the members, who agreed with him as to the cicatrization Dr J Collins Warren, of Boston, thought it a case of *noli me tangere*, a milder form of epithelioma Dr David Prince also saw the case The patient was rapidly improving when the supply of the drug became exhausted, and the disease is now as bad as before None of the recent applications have been at all useful Upon investigation, Dr Hamilton finds that other physicians have had the same experience, hence he concludes that alveloz as at present sold is either inert from deterioration, or fraudulent It is a resinous "juice," or "milk," gathered at certain seasons, and may deteriorate A fresh supply is expected soon to arrive In reply to a question of Dr Cook, he said his epithelial patient was said, in addition, to suffer from stone in the bladder, though he had not sounded his bladder Moreover, his general health was not good He had given him iodide of potassium whilst applying the alveloz When the alveloz gave out he continued the potassium in large doses without effect

Dr S S Adams said that when Dr Hamilton presented his first patient to the Society, Dr J Ford Thompson called attention to the fact that the ulcer was not completely healed and would doubtless return

Dr Hamilton said that the disease in this man had lasted for thirty years There was no pus and only a small bulla in one corner when Dr Hamilton brought him to the Society He was content with the freedom from trouble for four months, and a drug is certainly valuable which can exercise such a remarkable influence on an intractable ulcer

The American consul at Pernambuco sent specimens of the drug to the State Department, together with a history of the drug and its effect, this latter was written by a medical gentleman having a cancer hospital at Pernambuco It has been printed and can be obtained by application to the State Department The drug has been tried in France and England with varying results

STATE MEDICINE

PROPOSED NATIONAL BUREAU OF PUBLIC HEALTH

A BILL TO PREVENT THE INTRODUCTION OF CONTAGIOUS AND INFECTIOUS DISEASES INTO THE UNITED STATES, AND TO ESTABLISH A BUREAU OF PUBLIC HEALTH

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That there shall be established in the Department of the Interior a Bureau of Public Health There shall be appointed from civil life by the President, by and with the advice and consent of the Senate, a Commissioner of Health, who shall be intrusted with the management of the Bureau herein established He shall be paid an annual salary of four thousand five hundred dollars For his use the Secretary of the Interior shall provide suitable offices, and, with the approval of the same, he shall employ such assistants and clerks as may be necessary

Sec 2 That it shall be the duty of the Department of State to obtain from the consular officers at foreign ports and places all available information in regard to the sanitary condition of such ports and places, and to transmit the same to the Bureau of Health, and said Bureau shall also obtain, through all sources accessible, including State and municipal sanitary authorities throughout the United States, weekly reports of the sanitary condition of ports and places within the United States, and shall prepare, publish, and transmit to the medical officers of the Marine Hospital Service, to collectors of customs, and to State and municipal health officers and authorities, weekly abstracts of the consular sanitary reports and other pertinent information received by said Bureau, and shall also, as far as it may be able, by means of the voluntary cooperation of State and municipal authorities, of public associations, and private persons, procure information relating to climatic and other conditions affecting the public health, and shall make an annual report of its operations to Congress, with such recommendations as it may deem important to the public interests, and said report, if ordered to be printed by Congress, shall be done under the direction of the Bureau That the necessary printing of the Bureau of Public Health shall be done at the Government Printing Office upon the requisition of the Commissioner of Health, in the same manner and subject to the same provisions as other public printing for the several Departments of the Government

Sec 3 That the Commissioner of Health shall, under the direction of the Secretary of the Interior, frame rules which, when approved by the President and issued by the Department of State, shall serve for the instruction of consular officers of the United States and of the medical officers serving at any foreign port. In compliance with these rules, every master of a vessel destined for a port of the United States shall be furnished with a certificate containing a detailed statement of the inspection of the vessel, cargo, crew, and passengers, and of the sanitary measures carried out at the expense of the vessel, or if such measures are not carried out, instant warning shall be transmitted to the Bureau, who shall immediately notify the quarantine authorities of the port of destination

Sec 4 That the Bureau of Public Health shall, with the approval of the Secretary of the Interior, make investigations, both in the United States and, if necessary, in foreign countries, into the nature, origin, and prevention of contagious and epidemic diseases, as well as the causes and conditions of particular outbreaks of disease in the United States, and shall publish and distribute documents relating to the prevention of disease

Sec 5 That the President is authorized, when requested by the Bureau of Public Health, and when the same can be done without prejudice to the public service, to detail officers from the several Departments of the Government for temporary duty, to act under the direction of said Bureau, to carry out the provisions of this act, and such officers shall receive no additional compensation except for actual and necessary expenses incurred in the performance of such duties When a detail of suitable officers can not be made, the Commissioner of Health may employ such experts, and for such time and in such manner as the funds at the disposal of the Bureau may warrant, subject to the approval of the Secretary of the Interior

SEC 6 That to defray the expenses incurred in carrying out the provisions of this act the sum of seventy-five thousand dollars, or so much thereof as may be necessary, is hereby appropriated, to be disbursed under the direction of the Secretary of the Interior, on the requisition of the Commissioner of Health

SEC 7 That an act entitled "An act to prevent the introduction of contagious and infectious diseases into the United States, and to establish a National Board of Health," approved March third, eighteen hundred and seventy nine, and all other acts and parts of acts conflicting with the provisions of this act, are hereby repealed

SEC 8 That this act shall take effect sixty days after its passage, within which time the Commissioner of Health shall be appointed

FOREIGN CORRESPONDENCE

LETTER FROM LONDON

(FROM OUR OWN CORRESPONDENT)

The Queen and the New College—The Old Colleges—Carelessness in Dispensing Drugs—Brain Surgery of the Stone Age

The announcement that the Queen will lay the foundation-stone of the building which the College of Physicians and the College of Surgeons are conjointly erecting on the Thames Embankment has been received with marked satisfaction by the profession It is to Queen Elizabeth that medicine owes its emancipation in England from many an old world absurdity derived from Arabic and Pagan sources, for it was Elizabeth who, at the request of old Dr Caius—the founder of the college bearing his name at Cambridge—sanctioned the practice of anatomy in this Kingdom, and thus laid the basis for a systematic scientific study of the body It seems, therefore, quite in the fitness of things that another queen should lay the first stone of the new academic building in which the rival Colleges of Physicians and Surgeons have been merged Times have changed since the days of Dr Caius, the aid of the "barber chirurgeon" at the sign of the red and white pole or a "Jew leech" skilled in simples is no longer sought The pharmacopœia is not disfigured by the quack remedies found in the first edition, and compounded some of them of more than 120 ingredients It is hardly possible to read of the rival Colleges of Physicians and Surgeons conjointly erecting an edifice for any common purposes without recalling the jealousy and bickering that led to constant quarrels in former days The surgeons, or, more correctly, the barber surgeons, were the older body of the two, for they were incorporated by a charter granted to them by Edward IV The physicians were constituted a college by letters patent of Henry VIII To put an end to the "irregular, unlearned and incompetent" practitioners who abounded in those days, he formed the celebrated Linacre with four others into a medical faculty This provoked the ire of the surgeons, and quarrels grew apace In Elizabeth's time there was a notable difficulty between the physicians and surgeons "whether a surgeon might give inward remedies in the sciatica, pox, or any other kind of ulcer or wound" The Bishop of London and the Master of the Rolls were both in favor of the surgeons, and old Dr Caius, then President of the physicians, was called before "My Lord Mayor" and others of the Queen's delegates to "plead for his college" He did this so successfully that it was unanimously decided that it was unlawful for surgeons to administer medicines in the instances cited After this the surgeons quarrelled with their colleagues the barbers and severed the connection Then the two companies quarrelled so outrageously that Henry VIII reunited them again as a "Master and Commonalty of Barbers and Surgeons" They kept together till 1745, when the surgeons departed to the Old Bailey, and subsequently, in 1800, formed the body in Lincoln's Inn now known as the College of Surgeons

The original College of Physicians was Linacre's Stone House, in Knightrider Street The house was given to the Faculty during the lifetime of Linacre, who was one of Henry VIII's physicians One of the most useful things the college ever did was to form a botanical garden in 1587 for the cultivation of rare plants of medicinal value The garden cost "forty marks English money" a year, and the eminent herbalist, John Gerarde, had charge of it After the Civil War the college was on the point of being sold as "church property" when a member, Dr Baldwin Harney, became its purchaser It was burnt down during the great fire, and rebuilt in Warwick Lane, near St Paul's In 1814 the college obtained from the Legislature power to hold its meetings in Westminster, and in 1820, through the efforts of Sir Henry Halford, the present building of the College of Physicians in Pall Mall was erected The College can boast among its list of Fellows many whose names the entire civilized world holds in honor and would be unwilling to forget Caius, Harvey—who bequeathed to the institution, along with other things, his "best Persian long carpet" and "pair of brass andirons with fire shovel and tongs of brass," Sir Thomas Browne, Sydenham, Sir Hans Sloane, Radcliffe, who was foolish enough to tell Queen Anne 'he would not have her two legs for her three kingdoms," Pepys, Watson, Holland, and Arnott The roll of the Physicians' College includes also the

Duke of Montagu, admitted in 1717, and the Duke of Richmond, in 1729

An interesting report of an inquiry into the accuracy of chemists and druggists in the dispensing of medicines from physicians' prescriptions has recently been presented by Dr Seaton Within the past seven months Dr Seaton has sent fifty prescriptions to various chemists and druggists and, in conjunction with Dr Otto Hehner, has analyzed the medicines obtained In order to carry out the inquiry in a broad spirit and without incurring any charge of splitting straws by cavilling at insignificant inaccuracies, the authors of the report drew the margin of error at 10 per cent over or under the amount of the active drug prescribed in each case, and the deviations of wider mark than this have been singled out for comment Out of fifty examples this limit was exceeded in seventeen—that is, in thirty four per cent, while in eight of these cases, or sixteen per cent, the error exceeded twenty per cent of the active ingredient prescribed Some of these errors, except inasmuch as they implied a culpable carelessness, were medically of no great consequence, but some few were serious from a medical point of view In one case pills were ordered, containing mercury and hyoscyamus Owing to carelessness, the mercury was so unevenly distributed through the dozen pills ordered that some contained a third more mercury than they should have contained In another case where corrosive sublimate was ordered the mixture contained one third more than the prescription ordered In a third instance where sub acetate of lead was prescribed the mixture contained nearly sixty per cent in excess Of sulphate of iron there was found a deficiency of eighty-five per cent

It is gratifying, however, to learn on reading further that the credit of the ordinary chemist is less assailed than may at first appear from the foregoing statements Of the total number of fifty prescriptions thirty were made up at the shops of chemists and druggists, and among these thirty cases there were only two of serious error At "doctors' shops," not yet obsolete rivals of legitimate pharmacy, two medicines were made up, one of which showed one of the gross errors already referred to At the co-operative stores fourteen medicines were made up, which included three cases of serious error Four prescriptions were submitted to a "drug company," and of these no less than three were inaccurately dealt with to the extent of more than twenty per cent It would appear, therefore, that the public are safer in going to the shop of the ordinary qualified and registered chemist than in taking their prescriptions to the "doctor's shop" or to the cooperative store

Professor V Horsley has delivered an address on the "Brain Surgery of the Stone Age" Professor Horsley mentioned the fact that many of these apertures were in the part of the skull over the motor area, and thought that the operations were chiefly for traumatic epilepsy G O M

DOMESTIC CORRESPONDENCE

BRANCHES OF THE ASSOCIATION

To the Editor of the Journal

Dear Sir —I have carefully read the letters which have followed the appearance of "Branch's" communication, and am rather surprised at the position which some of your correspondents have taken

In his last letter (Journal of March 6) "Branch" states that his object is "to increase the influence of the Association, and organize the profession," while he distinctly deprecates any idea of abolishing existing institutions The only point on which I am not clear is where he says that "a very large amount of red tape would be taken away from the requirements for admission to the Association when respectable and reputable physicians desire to enter," the object to be attained is organization, and the results which inevitably follow where that is successful

I am in perfect accord with your correspondent when he writes "If anyone can propose a plan which will be more acceptable to the majority than the Branch system, I will certainly not raise my voice against it, but I do not see that a plan is *necessarily* bad because it is imported from Europe " No scheme can attain the end in view that does not provide for an executive meeting when required, to which business and legal matters can be entrusted There are other objects for the American Medical Association than the mere advancement of science, but so long as that body only exists practically at an annual session, these objects must remain in abeyance Dr Hamilton considers that all we desire would be gained by admitting the members of affiliated State Societies, while Dr Baxter advocates a regulation whereby members of the regular profession can join the Association without presenting themselves in person for election These suggestions are embodied in the amendment permitting membership by application, which has been in existence for nearly two years, yet the number of applicants during that period is hardly what might have been expected This would seem to show that some incentive is needed, and that the real advantages and benefits of membership in the National Association should be brought home to the profession

"State Society" deals indirectly with the question of finance when suggesting a method by which the transactions of existing Societies, if incorporated, could be published in The Journal I cannot agree with him that the stricter application of the doctrine of "survival of the fittest" will, in the long run, be beneficial It would damage The Journal to print many of the papers found in the annual volumes of transactions of our State Societies, yet I think that the publication of these very papers is most desirable Their production involves considerable time and labor on the part of the writer, who is usually not facile, and it is but slight encouragement to better work if they are consigned to the waste paper basket

The whole question of finance is the great obstacle to encounter, and the most difficult problem to settle I do not advocate the abolition of existing institutions, though I should be sorry to maintain them if a more effective scheme of organization can be found The position of a State Society under the contemplated change, if that Society became a "Branch," would remain precisely as at present, except that every member would pay $5 annually to the treasurer of the Association, all their rights and privileges could be preserved, and their autonomy would be then, as now, complete In any change which is contemplated, the same system of local representation would exist, and the profession in a given district would be *de facto* responsible for the ethical conduct and good standing of the members drawn from it I cannot see how any of the "crooks and charlatans," whom Dr Keller fears, would have any better chance of admission, while the salutary influence of the Association over them would be materially increased "Illinois," whose letter contains very cogent figures, says "red tape is thus reduced to a minimum, and yet there is no more probability of a bad man getting in than into one of our State Societies" This applies to the British Medical Association, and would be just as true of the American, if contemplated changes were carried out A qualification for membership would still exist, and could be so arranged as to make some members personally responsible for the applicant "Illinois" very properly deprecates what he terms the "holier than thou" sentiment There are, in every community, physicians whose tendency to wander from the paths of ethical regularity, is unfortunate and marked When these men are outside the pale of any medical organization, they are free, but once on the roll, it becomes possible to train and discipline them, and the punishment of formal expulsion for obstinate contumacy cannot be lightly regarded I would always favor the largest possible membership for a Society in its district, believing that the best interests of the profession are thus more readily furthered

An "Active Member" is the first correspondent who has formulated a definite scheme, and one which presents many excellent points

The Triennial Congress is a good suggestion, and disposes of the inevitable clashing which would result between annual meetings of Branches and the National Association Some plan on that basis would be most feasible, but further sub division might be advantageous, especially in the more densely populated Eastern States I do not concur with his suggestion No 5, as I believe that once organized a Branch should have control of its own members, and their election, and that the qualification should be membership in a local Society

"Medicus" lays down two purposes "to be aimed at" in any change which is to be made

1 To so increase the numerical strength of the Association, as to make it, by virtue of its representative power, "the supreme authority upon all questions bearing upon the interests of medicine, and the professional and social deportment of its members"

2 "The advancement of medical science, and the collateral branches, and the elevation of the medical profession"

Both these purposes are to be kept in view, but the first is far more important What the profession wants is thorough organization, and a permanent representative executive body

Medical science is advanced in a general way by annual reunions, at which the rank and file of the profession are brought face to face with the great minds of the day, but save as an intelligent audience, it does not individually benefit them Take the list of members at a State Society meeting, where one or two hundred are present, and see how few have papers to read, or cases to report, or will join in the discussions The true source of medical cultivation is in the local society, which meets once or twice a month, when every member participates in the evening's proceedings, without that hesitancy which prevents many coming forward in the larger assemblies Papers are read, cases reported, and criticism invited, while opinions are freely expressed, in a manner impossible except under these conditions They promote harmony and good fellowship amongst the profession, maintaining its dignity, and defining its position, by following Art VII of the Code Nothing can supplant them, and any scheme which may be proposed will be strengthened by their incorporation as an integral part Among the functions which the National Association performs, are those where matters of general professional interest are concerned, examples of which are well shown in an editorial in THE JOURNAL for March 6

The profession wants representation, so systematized that when questions of vital moment and great public interest are involved it can meet the State or Federal Government, as an authoritative exponent of the wishes and opinions of its constituents I believe that this purpose can in no way be so well served as by the establishment of Branches of the American Medical Association, and I think that the ends of medical science and medical policy will be best aided if these Branches are numerous, established in arbitrary districts, formed with due regard to the numerical strength of the profession in a given area, and meeting frequently, say three or four times a year

Yours truly,

JAMES H PARKINSON, L R.C S

Sacramento, Cal

To THE EDITOR OF THE JOURNAL

Dear Sir —I have been much interested in the letter published in THE JOURNAL of Feb 6, and signed "Branch," relative to the establishment of a more intimate relation between the various State Societies and the American Medical Association The plan which "Branch" has so admirably and clearly presented in his letter is almost identical with one which I have for some time carried in my mind, and which, but for the unfortunate state of confusion and dissatisfaction now existing [illegible] profession, I would have ventured to lay befor [illegible] of T[illegible]URNAL some time ago To [illegible] others, the adoption of a p[illegible] cieties may become more [illegible] National Association seems [illegible] about to say, the only way o[illegible] again into that state of harmony so essential to the development of the great benefits which the Association may, and most certainly should confer upon the medical profession of America.

From a train of circumstances which cannot now be recalled, but are passed into history, the American Medical Association does not enjoy that degree of support and encouragement from the profession at large which its importance, as a scientific body, and its position, as the National representation of the medical talent of our country, assuredly merit and should undoubtedly receive. This desirable result can in no way be so certainly attained as through the active sympathy and hearty co-operation of the various State Societies in the aims and objects of the Association, which really is made up of, and exists only through the State Societies. If each State Society will accept and fill its place in the formation of the Association, there will no longer be cause for just complaint of the conduct or management of the Association. The plan proposed by "Branch" may be the best one, though it differs in some minor details from the idea which was in my own mind, and I would willingly see it adopted in place of the one I am about to describe, or I would gladly give support to a plan differing from either of these if it should seem that the good of the Association could be furthered by something else, better than by these.

I cannot think that at this time the State Societies will consent to be assigned a position as simple *Branches* of the American Medical Association. Their real position should undoubtedly be that of a Branch of the higher organization, of which they should be the willing adjuncts and essential components. The National Organization should have no being apart from that as the representative of the best and noblest elements of the State Societies, and should find its greatest pride and its highest honor in their celebrated distinction. The State Societies should feel an individual pride in the formation of the National body and an individual responsibility for its character and actions as the representative of the medical profession of the United States, and thus watch over and protect the Association from the hasty or injudicious acts of thoughtless or designing members.

The form which has appeared to me the best for the accomplishment of the above objects would be something as follows:

1. The American Medical Association is to consist of Branches corresponding to the several States and Territories of the United States.

2. Each State or Territorial Branch is to be the official local representative of the American Medical Association, and the diploma of membership in any State Medical Society is to be a title to Associate membership in the National Association.

3. Each State Society should be represented by delegates, according to the membership of the State Society, one delegate to be chosen for each members of the State Society.

4. The delegates so chosen "pro rata" are to form the "council" or governing body of the Association, and to take charge of all its movements, subject to such restraints as may be thought judicious on the part of the Association.

5. From the delegates so appointed by the State Societies, the Officers of the Association shall be chosen, except the President, who may be chosen from without that body, or who may be elected in open meeting of the Association, by vote of the entire Association.

6. All members of State Societies who pay the dues of the American Medical Association, are thereby constituted Corporate members of the Association, and are entitled to take part in the transaction of business, and to receive the publications of the Association, and to enjoy all other rights and privileges pertaining to that body.

7. All other members of State Societies are thereby constituted Associate members of the American Medical Association, and may attend all the scientific meetings, and shall be enrolled in its catalogue, but they do not thereby gain the right to take action in its business meetings, nor to vote, nor do they receive the communications of the Association, or enjoy other privileges, except by permission of the coporate membership and the council.

8. The scientific labors of the Association are to be entrusted to committees chosen from the members of the council, from the Association at large, or from members of the medical or other professions outside the membership of the American Medical Association.

The plan here suggested, if it should be adopted, would have the effect of so enlarging the Association as to include the entire medical profession of the United States, so far as this is represented by State organizations as State Societies, and the diploma of membership in a State Medical Society would constitute the possessor of it at once an Associate member of the National Association, thus enrolling the entire State Medical Society membership in the membership of the National Association, as the body to which it naturally belongs, in this way attracting the profession to the Association, and inciting a more exalted degree of esteem and respect, and a greater emulation for that body, as the highest recognized medical organization of the country.

That this desirable object may be soon accomplished, and its beneficent results obtained is the ardent desire of many members of the medical profession in the BAY STATE.

ASSOCIATION ITEMS.

RAILWAY FACILITIES TO THE ASSOCIATION MEETING.—For the next meeting of the American Medical Association at St. Louis, Mo., from the 4th to 7th of May next, arrangements have been made with all of the principal railroads between the Atlantic ocean and Missouri river, to give delegates who pay full fare coming, return tickets at one-third fare. As yet the Commissioners of the Baltimore and Ohio, and Southern Passenger Association, not heard from. No doubt as to the same arrangements being made with them. In the next issue of this JOURNAL members will be fully advised of all arrangements with the various railroads. Delegates can come at any time they may wish before the meeting of the Association and will be allowed five days after the adjournment of the meeting, before they will be required to commence their return trip When purchasing tickets, get certificate from the railroad agent, at the starting point, showing the amount paid, the initals of road over which tickets reads, and office stamp where sold

Other weekly medical journals please copy

R M JORDAN, M D,
Chairman Transportation Committee
St Louis Mo

RAILWAY FARES FROM CHICAGO TO ST LOUIS — The Illinois Central, Chicago and Alton, and the Wabash Railways have agreed to fix the rates from Chicago to the meeting of the Association, for members, at $7 50 *round trip*

THE GRANT COUNTY MEDICAL SOCIETY AND THE ASSOCIATION —At a regular meeting of the Grant County, Indiana, Medical Society, on March 23, 1886, Dr William Lomox gave a short history of the difficulty or misunderstanding between the American Medical Association and certain members of the Executive Committee for the International Medical Congress, and offered a resolution of approval of the action of the Association The resolution was unanimously adopted S C WEDDINGTON, M D, *Sec'y*

RAILWAY FACILITIES TO THE ASSOCIATION MEETING —The regular through trains of the Illinois Central Railroad from Chicago to St Louis will afford excellent accommodations for delegates who wish to attend the meeting of the American Medical Association at St Louis the first week in May The night express, with Pullman sleeping cars, leaves Chicago at 8 30 P M, and arrives in St Louis at 7 A M The rates are $7 50 round trip

The rates on the Baltimore and Ohio Railway for those coming from the East and South east are full fare coming and one-third fare returning

AMERICAN MEDICAL ASSOCIATION

The Thirty-seventh Annual Session will be held in St Louis, Mo, on Tuesday, Wednesday, Thursday and Friday, May 4, 5, 6 and 7, commencing on Tuesday at 11 A M

The delegates shall receive their appointment from permanently organized State Medical Societies and such County and District Medical Societies *as are recognized by representation in their respective State Societies*, and from the Medical Department of the Army and Navy, and the Marine Hospital Service of the United States

Each State, County, and District Medical Society entitled to representation shall have the privilege of sending to the Association one delegate for every ten of its regular resident members, and one for every additional fraction of more than half that number *Provided*, however, that the number of delegates for any particular State, territory, county, city or town shall not exceed the ratio of one in ten of the resident physicians who may have signed the Code of Ethics of the Association

Secretaries of Medical Societies, as above designated, are earnestly requested to forward, *at once*, lists of their delegates

Also, that the Permanent Secretary may be enabled to erase from the roll the names of those who have forfeited their membership, the Secretaries *are, by special resolution*, requested to send to him, annually, a corrected list of the membership of their respective Societies

SECTIONS

"The Chairman of the several Sections shall prepare and read, in the general sessions of the Association, papers on the advances and discoveries of the past year in the branches of science included in their respective Sections "—*By-Laws*, Article 11, Sec 4

Practice of Medicine, Materia, Medica and Physiology —Dr J T Whittaker, Cincinnati, Ohio, *Chairman*, Dr B L Coleman, Lexington, Ky, *Secretary*

Obstetrics and Diseases of Women and Children —Dr S C Gordon, Portland, Me, *Chairman*, Dr J F Y Paine, Galveston, Texas, *Secretary*

Surgery and Anatomy —Dr Nicholas Senn, Milwaukee, Wis, *Chairman*, Dr H H Mudd, St Louis, Mo, *Secretary*

State Medicine —Dr John H Rauch, Springfield, Ill, *Chairman*, Dr F E Daniel, Austin, Texas, *Secretary*

Ophthalmology, Otology, Laryngology —Dr Eugene Smith, Detroit, Mich, *Chairman*, Dr J F Fulton, St Paul, Minn, *Secretary*

Diseases of Children —Dr W D Haggard, Nashville, Tenn, *Chairman*, Dr W B Lawrence, Batesville, Ark, *Secretary*

Oral and Dental Surgery —Dr John S Marshall, Chicago Ill, *Chairman*, Dr A E Baldwin, Chicago, Ill, *Secretary*

A member desiring to read a paper before a Section should forward the paper, or its *title* and *length* (not to exceed twenty minutes in reading), to the Chairman of the Committee of Arrangements, at least one month before the meeting —*By-Laws*

Committee of Arrangements —Dr Le Grand Atwood, St Louis, Missouri, *Chairman*

AMENDMENTS TO BY-LAWS

By Dr Foster Pratt, Mich —Each Section shall nominate its Chairman and Secretary—all other nominations to be made, as now, by the nominating Committee

By Dr I N Quimby, N J—Create a new Section, to be known as the Section on Medical Jurisprudence

WM B ATKINSON, M D,

DIGITAL EXPLORATION OF LUMBAR ABSCESSES

A Clinical Lecture delivered in the Mercy Hospital, Chicago (Service of Edmund Andrews, M D , and E Wyllys Andrews, M D),

BY EDMUND ANDREWS, M D , LL D ,

PROFESSOR OF CLINICAL SURGERY IN THE CHICAGO MEDICAL COLLEGE, AND SURGEON TO THE MERCY HOSPITAL

Were it possible to lay open a lumbar abscess throughout its whole extent, and treat it thoroughly in every part as an open sore, we would eliminate nearly all its dangers, except in tuberculous cases Now, by thorough digital examination of their interiors, followed by resolute incisions and tubing, we approximate to this condition of safety Let us see what may be done for the patient before us on this principle

He is not aware of the real nature of his disease, but supposes he has a hip disease There is a large fluctuating tumor on the outer side of the left thigh, below the trochanter, but pressure, rotation and friction of the joint surfaces upon each other elicit no pain There is no hip disease I now make a free incision into the abscess and evacuate almost a quart of pus Introducing my finger and long probes I trace the cavity, not to the hip joint, but upwards and backwards into the sciatic notch, where it enters the pelvis We will insert a large drainage tube and explore at a higher point Just over the posterior part of the crest of the ilium there is an old fistulous orifice, too small and contracted to allow a free discharge of pus This, I suppose, opens into the same inner passage which goes downwards through the pelvis, out of the sciatic notch and into the great abscess of the thigh We will open it widely and cut off the supply of pus to the cavities below

Introducing my finger I find the usual expansion of the sac under the skin, with a narrow inner orifice leading to the interior of the body I enlarge this inner passage with the bistoury, and now can insert my finger into the cavity of the trunk behind the thickened peritoneum At this point I find a channel extending down towards the sciatic notch, and also a pouch like passage running forwards along the internal iliac fossa and expanding into a sac behind the region of the anterior superior spinous process and the outer third of Poupart's ligament Here the thickening of parts and pressure of the abscess have pushed away the peritoneum, making plenty of room for another incision Passing a bent metallic staff into this pouch I feel the pressure of its extremity, and cut down upon it from without, with a free incision I can now introduce a finger into the anterior orifice, and another into the posterior one, and bring them together in the cavity We will next pass a large drainage-tube through, leaving an end out at each orifice

Returning to the posterior incision, I insert the finger again, and trace another channel upwards behind the bistoury and within the lower ribs I now cut down upon my finger just below the twelfth rib, alongside the common mass of the spinal muscles, and carry another long and large tube down from this orifice, bringing its lower end out through the orifice below, alongside the posterior end of the iliac tube We can trace with the probe a canal running still upwards to the ninth dorsal vertebra, where we find externally the usual projecting knob characterizing Pott's disease Here is the fountain head of the pus which has burrowed through all the long and complicated passages below, exhausting the patient, not by drainage, as the old surgeons said, but by the want of drainage, or more accurately, by the absorption of putrid pus from all these vast interior surfaces, which will now collapse down upon the tubes and become healed

There still remains the short passage from the upper orifice to the carious bone We might excise a portion of the ninth rib behind, and endeavor to scrape away all carious bone from the vertebra, but in doing so we should have to deal with the ninth intercostal artery, which winds across the body of the affected vertebra in a situation which renders it pretty difficult of management Our incisions and tubing below, followed up with antiseptic injections, will relieve the patient of most of the causes of his debility The upper short segment of the channel between the upper incision and the affected bone is too small in extent to cause great debility, and we will inject it daily with antiseptics, under which treatment not a few cases will heal, the carious spicules of bone being partly washed away and partly absorbed If this result be not accomplished, we will resort to a plan by which I have often removed dead bone from different parts of the body inaccessible to instruments I refer to the solvent use of diluted hydrochloric acid, a resource which is strangely neglected by most surgeons To carry out this plan it will be necessary to open the intercostal space opposite the affected vertebra, widening this space, if necessary, by cutting a broad notch in the rib below

Now, passing up from the incision below a sound or catheter, and identifying its location by touch or by the use of needles, we cut into the abscess cavity at its very fountain head If the dead bone be found loose, we can then pick it out, if not, a tube is inserted well against the bone, and being attached to a fountain syringe full of diluted hydrochloric acid, it transmits a quart of the solvent slowly against and across the carious spot This is repeated daily, and if the bone is fairly reached by the tube every dead particle is effectually dissolved out The incision is kept well open by a good drainage-tube until the cavity within is healed

When the lumbar vertebræ are affected they are much more accessible The finger can come directly upon them, and there being no intercostal arteries there, they can be scooped and scraped, if one simply avoids the aorta and the vena cava A few days ago I explored such a case Opening into the abscess alongside the erector spinal muscle, I found a pus cavity about five inches long extending up and down, and perhaps two and a half inches wide In it lay two very small pieces of dead bone, which I removed The third lumbar vertebra had been affected with caries, causing the usual external deformity Exploration by the finger within showed a considerable concavity in the side of the body of the vertebra, but it was fully healed, being firm and well covered with granulations The size of the cavity showed that much more bone had been lost than was accounted for by the pieces found The remainder must have been either absorbed or washed away

A careful examination by the finger and the probe showed that the caries was completely healed, and that under simple tubing and antiseptic injections the abscess will be permanently cured

THE VALUE OF BINIODIDE OF MERCURY AS AN ANTISPETIC IN OBSTETRICS[1]

BY EUGENE P BERNARDY, M D

At a meeting held June 4, 1885, I had the pleasure of reading before this Society a paper on the "Value of Biniodide of Mercury as an Antiseptic in Obstetrics" It was with hesitancy that I brought forward the claims of a new agent whose properties were at that time comparatively unknown My only knowledge of its effects was that which I had derived from reading the experiments of Dr Miquel, of France, and from my experience in three cases To-night I again bring it to your notice, not as an unknown and untried antiseptic, but as one which has proved itself far superior to any of this class of preparation which I have thus far used in obstetric practice Since writing my last paper I have learned that the biniodide of mercury has been used for the past year in preference to all other antiseptics at the Lariboisière Maternité, of Paris, and the reports of the results obtained have likewise been highly favorable

In a letter written by Dr Thos Linn from Paris, France, to the *Philadelphia Medical Times* (March 6, 1886), referring to the subject of antisepsis, the following passage occurs

"Professor Panas has again something to say about antisepsis in eye surgery, principally in the treatment of cataract The principles that guide him are, first, to make use of an antiseptic that is *sure* and *not irritating* in its action Of all the antiseptics which he has used during the last two years, Dr Panas has now definitely adopted a solution of the biniodide of mercury in 20 to 1000 ($\frac{1}{20}$ to 100?)[1] Even in 40 to 1000 ($\frac{1}{40}$ to 1000?), this salt possesses a very strong anti fermentative power, so that at double the strength nothing should resist it As to the other antiseptics used, boric acid is not irritating, but its antiseptic power is doubtful, the bichloride of mercury is more irritating than the biniodide, and its antiseptic power is not half so great"

These remarks fully substantiate the opinion expressed in my former paper, that "I considered the biniodide of mercury far superior to the bichloride of mercury as an antiseptic" Of course, the cases of Dr Panas belong to eye-surgery, but still the experiments made in both classes of cases led to the same conclusions

I have here the history of eight other cases in which I found it necessary to use the biniodide I have perhaps given a fuller detail of circumstances than may appear necessary If I so erred, I have done it for the purpose of fully and clearly showing under what conditions the antiseptic was used

It will be observed how readily offensive odors disappeared after only a few injections of the biniodide In some of the cases the odor around the patient was perfectly horrible

Case 1 —On September 9, 1885, I was requested to attend Mrs F, residing at Fifty fifth and Vine Streets, in her fifth confinement Her previous labors had taken place in Belgium, and had always been terminated by the forceps, only two children being born alive The first and third lyings in were complicated by attacks of puerperal fever

I arrived about 2 P M Found the patient had been in labor since the previous evening (8 P M) On examination, found the os completely dilated, head presenting while to the left I felt what seemed to be a prolapsed cord The head seemed jammed between the promontory of the sacrum and the pubes I ruptured the bag of waters so I could make a more decisive examination Down came a loop of non pulsating cord, which proved to be irreducible on account of the position of the head The presentation was now made out to be a partial brow, an antero posterior contraction existed, the promontory of the sacrum caught the side of the head and pinned it in position I attempted to push the head up, but soon found it could not be done I then attempted to produce flexion, and failed Wallace's forceps met with similar results, on account of the unnatural position of the head, the forceps constantly slipped By this time I was completely exhausted I gave one half grain of morphiæ sulph, which would insure the patient needed rest, as her pains had all along been active

---

[1] Read before the Obstetrical Society of Philadelphia April 1 1886

[1] Evidently an error in proportion as in the formula given it is 1-20 gramme to the litre or 1 to 20 000

On my return at 5 P M, found the condition of things the same Dr A E Roussel, who came with me, etherized the patient I again attempted to change the position of the head, but failed Pagot's long forceps were applied, but on the slightest traction they would slip Tarnier's forceps seemed to grasp the head in a firmer manner, but they finally gave way I had now worked continuously for two hours Seeing there was no other resource, I perforated the head, and within twenty minutes the child was extracted, which weighed, without the brains, fifteen and one half pounds

The patient was living on the second floor, in a room partitioned off the main room of a factory The room was well located and freely supplied with fresh air, her husband was the nurse The next day found the pulse 100, temperature 101°, extreme tenderness over the abdomen, especially over the region of the uterus I washed out the uterus with the $\frac{1}{15000}$ solution of the biniodide of mercury, and left orders to have it done four times a day The second visit found the patient free from pain, pulse 80, temperature 98⅛ Convalescence went straight on as in a normal labor On the fourth day there was considerable pain over the uterus Towards evening, while washing out the vagina, a clot of blood about the size of a pigeon's egg was expelled, perfectly free from odor The patient was up on the eight day

Case 2 —Was called (October 5, 1885) to attend Mrs Mc, age 30, third confinement After an easy labor she was delivered of twins The placenta came away naturally, and everything went well up to the evening of the sixth day, when she became feverish and thirsty The vaginal discharges became highly offensive, so much that the windows had to be constantly kept open I immediately ordered injections (hot) of the $\frac{1}{4000}$ solution of the biniodide of mercury, asking the patient to note particularly when the odor disappeared The first injection was followed by no effect, but on the second injection being made, the odor disappeared and remained so during convalescence Discharged on the tenth day, well

Case 3 —On the morning of October 7, 1885, I was called to attend Mrs B, age 28, sixth confinement About a month previous she had called at my office, and I had given my opinion that the child she was carrying was undoubtedly dead, and that she was likely to fall in labor at any time On my arrival at the house, found, after examination, the os perfectly dilated and the bag of waters protruding between the vulvæ Ruptured the bag of waters, and of all stenches I never smelled the like The windows had to be thrown open On pushing my examination, found a small hydrocephalic child descending Labor was lingering, but finally the child (in a putrid condition) was expelled naturally The placenta came away without any trouble

I ordered the patient to be washed out with $\frac{1}{4000}$ solution of the biniodide of mercury four times a day The first injection I administered myself The second and third injections were followed by a slight stinging sensation, which I believe came from using water which was too hot, but, to make certain, I reduced the biniodide to the $\frac{1}{8000}$ Within two days the discharges became perfectly odorless Each injection was followed by a feeling of ease and comfort Discharged well on the ninth day

Case 4 —On October 23, 1885, I was requested to attend Mrs R, in her fourth confinement Her third lying in had been followed by a severe attack of puerperal fever Upon examination, found the os rigid, dilated about an inch, waters ruptured, vertex presentation, right occipito-posterior position Labor was lingering, os remaining somewhat rigid About 9 P M, finding that no headway had been made, and the patient by this time showing symptoms of exhaustion, she was then fully etherized I then applied Wallace's forceps and delivered her of a living child, no laceration The next day she complained of pain over the region of the uterus Ordered one-eighth grain morphiæ sulph in tablespoonful of camphor water every two hours On my next visit found the tenderness had increased and the discharges from the vagina were becoming offensive Ordered hot injections of the $\frac{1}{4000}$ solution biniodide of mercury The following day the discharges were free from odor, the tenderness of the uterus abated Discharged well on the fourteenth day

Case V—On the morning of November 3, 1885, I was asked to see Mrs C, first confinement In this patient a year previously I had dilated a constricted os Pregnancy was ushered in with marked kidney trouble, the urine yielded over thirty per cent of albumen The patient was enormously swollen from dropsical effusion The case from the start was not a promising one On arriving at the house, found the patient very nervous, on examination, found the os slightly rigid, but dilating, the waters ruptured, labor dragged on slowly all day, with very little advance Towards 12, midnight she suddenly went into a spasm I immediately etherized her By the time she was completely etherized Dr Curtin, whom I had sent for, arrived On examination the os was found dilated, slightly rigid, the ether was pushed, with the effect of softening the os I then applied Simpson's forceps, but they would not hold, Wallace's long forceps were applied, and in a short time the patient was delivered of a fine bouncing boy, no laceration

The next visit found the patient doing well, pulse about 80, temperature normal On my second visit the temperature was 120°, pulse 120–130, great fever, excessive tenderness of the uterus, the discharges very offensive This sudden change was caused by the stupidity and incompetency of the nurse The nurse being discharged, the mother of the patient undertook to nurse her I immediately ordered hot injections of $\frac{1}{4000}$ solution of biniodide of mercury

The second injection the odor disappeared, but in this case did not remain away, I believe it was on account of not having a competent person to use the injections Even as imperfectly as my orders were carried out, the biniodide held the odor under control as the discharges were never as offensive as before its use The patient was discharged well on the fifteenth day

Case 6—On November 11, 1885, I attended Mrs L in her fifth confinement, her last two confinements had been followed by puerperal fever She had been delivered by an excellent and careful obstetrician She dreaded the present confinement On arrival found the child was born, in a short time the placenta came away The next visit found the patient doing well, with the exception of some tenderness over the uterus Being compelled to leave the city, I handed the case over to Dr A E Roussel On his first visit the patient was feverish, pulse 100, temperature 101°, discharges extremely offensive, excessive tenderness over the uterus Internally, 2 grains of quinine and ⅛ grain morph sulph were ordered every three hours, and four times a day hot injections of the $\frac{1}{4000}$ solution of the biniodide of mercury On his next visit found the patient better and the discharges free from odor The patient was discharged on the ninth day well, feeling satisfied that the *red pills*, as she called the pellets of the biniodide, had saved her from another attack of puerperal fever

Case 7—Mrs B, on December 28, 1885, miscarried about the fifth month On my arrival at the bedside, found the fœtus had been expelled early during the day, the hæmorrhage had been excessive, on examination, found shreds of placenta in the vagina, could detect a larger portion in the uterus The patient declined any interference, stating that it would come away itself The patient lived in a small, ill-ventilated house, up a court, having for nurses the neighboring women Gave freely of ergot, but without effect, within twenty-four hours the odor from the vaginal discharges was highly offensive, ordered the $\frac{1}{4000}$ solution of the biniodide of mercury to be thrown up the vagina four times a day, a few injections readily dissipated the odor On the fifth day the remaining portion of the placenta came away, free from odor The patient was discharged well on the tenth day

Case 8—On March 26, 1886, I was requested to attend Mrs ——, wife of a physician On my arrival at the house found that labor pains had set in about 4 A M Saturday morning, examination showed the os soft and dilating, waters broken, vertex presentation Labor continued throughout the day, and terminated naturally at 10 15 P M, no rupture of the perineum, but the mucous membrane of the vagina, just behind the posterior fourchette, yielded to the extent of half an inch, there was a tendency to post partum hæmorrhage, which was readily checked by compression and the administration of ergot Next day, pulse 92, skin rather hot, natural flow from the vagina On my next visit, Monday, March 22, pulse 130, temperature 103½° pain over the left side of the uterus, the uterus appeared flabby, not having well contracted Same day at 5 o'clock, pulse 130, temperature 104°, discharges from the vagina highly offensive Ordered the vagina to be washed out with a solution of carbolic acid (twenty per cent), ten grains sulphate of quinine morning and night, and twenty drops tincture of digitalis every three hours Midnight, same day, pulse irritable, quick and compressible, pulse 128, temperature 103°, the discharges from the vagina still offensive Next morning, temperature and pulse the same, no change Ordered the $\frac{1}{4000}$ solution of the biniodide of mercury to be thrown up the vagina, and if possible into the uterus, the injections were administered by the husband, and were thoroughly applied On the 24th the condition of the patient seemed improved, temperature 102°, pulse 115–120

On the next morning the husband called at my house and informed me that his wife was in every way worse, the pulse was so irregular that he could not count it, temperature 104°, patient vomited several times, tendency to diarrhœa I asked Dr Goodell to meet me in consultation On arriving at the bedside of the patient, found her in a remarkably good condition, pulse 100, temperature 102°, examination showed a slight laceration of the mucous membrane in the vagina, uterus was contracted, treatment to be continued, with this addition if the case did not get along well To use 10 grain vaginal suppositories of iodoform in conjunction with the biniodide injection These suppositories were not used, as the case from this day did well, with this exception, that on the 27th of March, or the seventh day of confinement, she was allowed to get up and use the night vase This was followed by a severe secondary hæmorrhage, which was checked by hot-water injection and ergot From this time the biniodide was used, the vaginal discharges were free from any offensive odor, and it seemed to have a decided influence on the temperature The patient is still under treatment

We have here eight cases added to the three of my first paper, making in all eleven cases This certainly gives us sufficient data to draw conclusions

The deductions drawn from my early cases are fully sustained by my subsequent experience, and in my mind fully establish the value of the biniodide of mercury as an antiseptic in obstetric practice

In my first series of experiments, to make my solution of the biniodide I took 1¾ grains of the salt, placed it in a mortar, and gradually broke up its particles, after which I slowly added one pint of boiling distilled water This gave me a $\frac{1}{4000}$ solution This took a long time, and often alchohol had to be added to dissolve the mercury

Mr J F Hayes, of St George Pharmacy, conducted a series of experiments for the purpose of placing the biniodide in the hands of the physicians in a convenient and readily soluble form To obtain this end pellets were made of three different strengths In making them sufficient iodide of potassium was added for the purpose, though not enough to cause any chemical change with the biniodide The following is the method pursued in making the pellets Both salts should be perfectly dry The potassium iodide is first placed in a mortar which has been slightly warmed (just enough to take the chill out of it, and thoroughly powdered, the biniodide is then added and well mixed, but not rubbed hard, or the powder will be apt to cake Care must be taken not to compress the pellets too hard, they keep just as well and are more easily dissolved when they are compressed just hard enough to make a firm pill The following is the formula for the pellets

$\frac{1}{4000}$=mercuric iodide $3\frac{21}{25}$ grains, potassium iodide 2 grains Mix as above, and compress in pellet

$\frac{1}{8000}$=mercuric iodide $1\frac{23}{25}$ grains, potassium iodide ¾ grain Mix as above and compress in pellet

$\frac{1}{15000}$=mercuric iodide $1\frac{5}{2500}$ grains, potassium iodide ½ grain Mix as above and compress in pellet

In this form the preparation can easily be carried in the satchel When required for use one pellet is to be added to a quart of hot water (110°) It dissolves easily, and does not stain the clothing or bedding

The strength which I generally use is the $\frac{1}{4000}$ Should it appear too strong the pellet can be cut in half or twice as much water used, thus giving a $\frac{1}{8000}$ strength

221 South Seventeenth Street, Philadelphia

SAN DIEGO VERSUS THE ORDINARY DISEASES

BY C M FENN, A M, M D,

MEMBER OF STATE MEDICAL SOCIETY OF CALIFORNIA

Inquiries concerning this climate in its bearing upon disease are so frequently addressed to the writer by members of the profession and laymen, that I venture to furnish a list of questions and responses For this purpose I avail myself of a series of interrogatories sent to me by some one who is apparently engaged in the collective investigation of diseases (?) The subject may be of increased interest to some by reason of the multitudes of people that are at present coming to this locality from all directions Within a twelvemonth thousands have been added to the population and hundreds of thousands to its material wealth But to the questions

"To what extent and at what seasons have the following diseases prevailed in your section during the years 1884 and 1885?"

Cholera infantum occurs sporadically, if at all The temperature is neither sufficiently elevated nor prolonged to produce the typical disease

Cholera morbus is neither frequent nor influenced by the seasons, owing, doubtless to the constant presence in market of fresh fruits and vegetables However, from some unknown cause it was unusually prevalent from August to October, 1885

Diarrhœa is seldom epidemic During outbreak of cholera in Spain, however, there was a noticeable increase of cases of diarrhœa in this locality

Dysentery occurs sporadically only, and without reference to the seasons

Measles is never extensively epidemic, and not particularly governed by temperature

Scarlatina No epidemics of magnitude during the period mentioned A few cases appeared in the winter of 1884

Diphtheria and *diphtheritic sore throat* have twice prevailed to a limited extent within the time stated Death, when it occurs, from laryngeal complications and blood-poisoning

Croup sometimes prevails during winter months, a predisposition to the disease being an important factor

Erysipelas The phlegmonous type rare, and not prone to complicate surgical operations Erythema, or erythematous erysipelas of more frequent occurrence

Intermittent fever I have never seen an endemic, or indiginous, case of chills and fever here

Remittent fever A mild type is sometimes met with among children during autumn months

Typhoid malarial fever is certainly never endemic, and rarely found here

Typhoid fever is comparatively unknown We have a California typhoid, without the intestinal lesion, a version of Hamlet, so to speak, with the Prince left out

Cerebro spinal fever Sporadic cases have been reported Do not think this climate congenial to it

Phthisis pulmonalis There are always some cases, but they are generally imported Native races are not wholly exempt I have never known a white person to contract it here

Rheumatism Sporadic cases of the acute form occur Chronic rheumatics prefer this to many other coast climates

Pneumonia is never epidemic Occasionally met with in wet seasons

Pleurisy I do not think it of frequent occurrence Intercostal and left-side pains are often mistaken therefor

Bronchitis occurs here chiefly as a sequel, or intercurrent, to other diseases of childhood

Congestion of the lungs may occur sporadically and after unusual exposure Consider it a rare malady

Influenza An epizootic or influenza (?) has twice been epidemic during the last eight or ten years

Catarrhal fever If coryza be implied in the term, we are not wholly exempt during wet seasons Medical treatment is seldom required

Enteritis I have met with two cases during the period named

Peritonitis, idiopathic, Of rare occurrence here

Diseases of the liver Functional disturbances are not uncommon, especially among the unacclimated Organic lesions, except from intemperance, are rarely found

Nephritis, acute idiopathic Not often observed by the physician A deal of "Safe Cure" is consumed by the laity for flatulence, or tapeworm (?)

Heart disease Usually imported Such cases seek climate as well as others

Infantile convulsions Sporadic cases only This is a terrestrial paradise for babies

Puerperal fever I have never had a case in San Diego during a residence of more than twelve years

Of all the ills, affections of the fauces, such as tonsillitis and follicular inflammations, are most prevalent The former usually ends in resolution, and the latter yields readily to judicious treatment

Any one desiring further and especially meteorological data is respectfully referred to my contribution to the last census, made at the request of the department

San Diego, March 10, 1886

ERYSIPELATOUS ECZEMA

BY GEO N MONETTE, M D ,
OF NEW ORLEANS LA

I have observed, during my past year's experience, a great number of cases of an exanthematous eruption, which, from the prodromal phenomena and the subsequent ultimate pathological phenomena, I am compelled to denominate "erysipelatous eczema" As an initiative, a rigor, with features of a pyretic nature, vertigo slight, a tongue slightly coated, with a metallic taste, some pains, arthritic in locality, urine somewhat highly-colored, pulse somewhat excited and full, consonant with the succeeding turgescence of the cutaneous surface

The primary features, naturally, so greatly resembling scarlatina, would lead one to diagnosticate a case of the latter named malady, yet upon close observation, it develops into an acute form of dermatitis There were other features indicating an attack of erysipelas pure, in its primary manifestation, yet there were no bullæ, and no apparent anasarcous condition of the integument, as in erysipelas, but with a vigorously congestive and hypertrophied condition, sometimes corrugated and corded like elephantiasis Itching was an intolerable accompaniment, yet no wheals were present, as in urticaria, no exudative plastic fluid, as in eczema, and no exfoliation as profuse as in eczema chronicus

Dermatitis acutus would be a suitable synonym, yet owing to the characteristic features, I think the compound term more expressive The duration of the malady was from one to three weeks, unlike erysipelas, running its prescribed course within five days, with no unusual developments, as one might apprehend from such an universal congestion, so to speak, of the whole cutaneous surface, with peripheral paresis of neurosal filaments The last case, as I observed it, presented a pachydermatous condition with rugæ and some exfoliative desquamation, disfiguring the face of the old lady considerably Her general health was and had always been good, and there were no extraneous concomitants to arouse any suspicion of infection The features present were identical with those seen previously

Now as to the causes I did observe some years since that several cooks whom I had treated developed *bona fide* eczema of the face, neck and forearm I can recall some of washerwomen who suffered with an eruption on the hands and forearms, yet in these I ascribed the same to the strong chemical and lye soaps used All were amenable to suitable therapeutics In the above cases I could detect no cause, other than hæmato-dyscrasia There were no cases contiguous, no wounds which might have been the media of imbibing or localizing any specific virus

The therapeutics were such as the cases indicated, principally ferruginous tonics, quinine added, and alkaline ablutions to counteract the intolerable itching or pruritus Arsenic was combined with the tonics, also ergotin was given to stimulate proper contractility of the cutaneous vessels One lady, in her incipient development, was annoyed by persistent nausea, which I obviated by a small mercurial with soda I had had a practicing physician boast to me some months prior, that he had quite a number of cases of erysipelas If there was any resemblance at all in the cases, I am sure that my cases were not erysipelas Urticaria has been a frequently recurring ailment in my experience, and has always been susceptible of ready relief I have not had any so severe as to approximate to the subject of this sketch

I feel that the symptoms will sustain me in my denomination of the malady, an erysipelatous eczema, the latter characteristic of red eczema

INTUBATION OF THE LARYNX

BY L H DUNNING, M D ,
OF SOUTH BEND IND

O'Dwyer's method of intubing the larynx for the cure of membranous croup being under trial, the following history of an unsuccessful case is written in order to swell the list of recorded cases from which, when large enough, we must draw our conclusions as to the efficacy of the method

On March 20 I received a note from Dr J B Green asking me to come immediately to Mishawaka to see a patient of his, and to bring my O'Dwyer instruments On reaching the bedside of the patient I found a child 2½ years old laboring under membranous croup, which had been in progress for eighteen hours There was marked cyanosis, labored breathing and great prostration These conditions had been gradually developing for several hours, and had now reached the point of jeopardizing the life of the child Dr Green and I agreed that unless instrumental means afforded relief death would be the inevitable result of the attack Therefore, in what we deemed the discharge of our duty, we proceeded to intube the larynx

The patient being slightly under size, we selected a tube modeled for a two years' old child The usual method of introducing the tube was observed, and I found little difficulty in properly placing it in the larynx The tube afforded marked relief, and when the thread was removed the relief as evidenced by the patient's appearance was striking She now breathed easily, the cyanosis disappeared, and she passed into a quiet natural sleep After watching the patient for half an hour, and observing that the tube caused but little local irritation, and that the patient continued to breathe and rest easily, we directed that she should take as nourishment only warm milk, and then left her to the care of efficient nurses

March 22, 8 30 A M —Pulse 120, respiration 22 temperature normal Patient had rested well during night Had coughed considerably on taking milk or water, but was breathing easily The skin was of normal hue, and the patient was bright and cheerful, being inclined to notice her playthings

March 22, 12 M —Dr Green reported patient as in a favorable condition No fever, pulse 118 to 124, and respiration 20 per minute

March 23, 4 P M —Saw the patient with Dr Green An entire change had taken place in the condition of the child The tube was yet in position and there was no obstruction to respiration in the larynx, but there were all the physical signs of an intense and widespread broncho pneumonia The attendants attributed the unfavorable change to the imprudence of the father of the child in carrying it from a warm room into a cool one, as two or three hours after the change had been made there were evidences of the development of the lung trouble The child died at 8 P M of broncho pneumonia

The tube was removed a short time before death and found unobstructed The relief afforded during the first two days by the presence of the tube was marked, and it is the opinion of the attending physicians that had not the imprudent act been performed the night of the 22d the child would have made a good recovery

INSTANCES OF TWO OR MORE CASES OF DIABETES MELLITUS IN MEMBERS OF THE SAME FAMILY OR IN NEAR RELATIVES

BY AUSTIN FLINT, M D , LL D ,

PROFESSOR OF PHYSIOLOGY IN THE BELLEVUE HOSPITAL MEDICAL COLLEGE NEW YORK CITY

Number of instances in which complete family histories were obtained, 36

Number of instances in which but one case in a family was noted, 27

Number of instances of two or more cases, 10

No 1 Father–daughter (Both cases observed and recorded)

No 2 Brother–sister (Case of sister only observed and recorded)

No 3 Mother–son (Both cases observed and recorded)

No 4 Paternal uncle–nephew (Case of nephew only observed and recorded)

No 5 Brother–sister (Both cases observed and recorded)

No 6 Two sisters (One case only observed and recorded)

No 7 Two sisters (One case only observed and recorded)

No 8 Two brothers (One case only observed and recorded

No 9 Two brothers (One case only observed and recorded)

No 10 Father, paternal uncle, two sisters, two brothers (One case only observed and recorded)

(Note) Nos 1, 3, and 5 are reckoned each as one instance in the thirty six

MEDICAL PROGRESS.

RAPID DILATATION OF THE CERVIX UTERI FOR DYSMENORRHŒA AND STERILITY —DR A H GOELET of New York, in a paper on this subject, says

The proper time for dilatation, is from one week to ten days after the cessation of the menstrual flow Much can be accomplished by preparatory treatment, in relieving the rigidity and congestion of the parts, by using every second day for a week previous to the operation, a tampon saturated with either glycerine or boroglyceride A string being attached, it is removed by the patient in twenty four hours, and the vagina thoroughly irrigated with hot water

The instrument preferred is the Palmer dilator, modified in the following way, viz The blades are made thicker near the shoulder, and the outer surfaces flatter, to lessen the risk of injuring the cervical mucous membrane, and to prevent too much spring, and the shoulder is made more abrupt The amount of separation of the blades is one inch, at a point corresponding with the internal os, when the instrument is in position For greater convenience, the thumb screw attached to the handles has been transferred to the left side

The operation is thus performed The patient having been anæsthetized and placed on a table in a good light, with the second assistant, who may be a nurse, standing to the right of the patient (left of the operator), the speculum is introduced and the cervix exposed to view Ordinarily the position on the back with a bivalve or trivalve speculum will answer every purpose, but for cases where much flexion exists the Sims's position and speculum are required Unless it has been previously done, the sound is introduced first to ascertain the direction of the canal Then, fixing the cervix, and drawing it down slightly with a tenaculum in the left hand, the dilator, held in the right, is introduced through the external os without much difficulty, but its progress is arrested at the internal os, where the obstruction generally exists But steady, firm pressure exerted in the proper direction will usually overcome the obstruction, and the beak of the instrument jumps suddenly through the internal os The shoulder on the blades limits the amount of penetration and prevents injury to the fundus Where steady and firm, but gentle, pressure does not overcome the obstruction, I prefer to withdraw the instrument and pass successively applicators wrapped tightly with cotton, increasing the size until the dilator can be introduced without force Harsh means cannot be too strongly condemned I have never found it necessary to bore the external os with a pair of pointed scissors, and consider it a harsh and unnecessary procedure Should an exceptional case present in which it was impossible to pass the probe, I should introduce a small laminaria tent and wait

When the blades have been introduced as far as the shoulder, the handles are gradually brought together, the thumb screw being made to follow along and hold the advantage gained when the hand becomes tired, or the dilatation may be done with the screw alone The amount of dilatation is usually the full extent of the instrument (one inch), but this depends upon the case After a few moments the screw is loosened and the instrument is withdrawn The canal is then cleansed of mucus by means of applicators wrapped with absorbent cotton, and a hard rubber bougie (Hawk's), No 13 American scale (20 French), is gently passed, followed by successive sizes up to 18 if the case require it After this, an applicator armed with cotton and dipped in liquid carbolic acid is passed through the cervical canal A tampon of absorbent cotton saturated with the boroglyceride, fifty per cent with glycerine, is placed against the cervix and the patient is transferred to the bed to recover slowly from the anæsthetic Besides possessing antiseptic properties, the boroglyceride depletes the tissues and relieves irritation

The stem used in the after treatment is of hard rubber two inches long and slightly curved, having a cup-shaped shoulder which hugs the cervix and remains in position better than the glass stem I formerly used It is tunnelled or perforated through the centre to allow drainage There are three sizes, 10, 12, and 14 English, corresponding with sizes 13, 15, and 17 of the American scale Its introduction is best accomplished by means of the sponge tent applicator, the end of which is made to fit in the perforation By using this the stem can be introduced very nearly straight, even when there is considerable flexion The curve in the instrument takes the place of the curve in the stem and allows the point of the stem to pass the angle in the canal with greater ease By seizing the cervix on the side with a tenaculum, and pressing the stem firmly into the canal, carrying the handle of the instrument well back toward the perineum, its introduction is facilitated In retroflexion the movement is reversed

On the day following the operation the tampon is removed, the canal cleansed of mucus, and the hard rubber dilators are again passed, after which the stem is introduced as described above and held in position by a similar tampon of cotton soaked with the boroglyceride This is repeated every day, the stem being removed, cleansed, and replaced After a week of this treatment, during which time the patient is confined to her bed, the stem is removed permanently and she is allowed to get up In some instances the stem is introduced curved at first, and after the uterus has become accustomed to its presence it is straightened

The conclusions arrived at are

First That rapid dilatation is a perfectly safe, justifiable, and satisfactory procedure, free from the dangers which frequently follow the cutting operations, especially the occurrence of cicatricial contraction

Second If the stem be used in the after-treatment, recontraction does not occur, and the operation does not require repetition

Third The operation is demanded by the following conditions viz, (1) Marked stenosis with or without flexion (2) Acute flexion without actual stenosis, the obstruction existing only coincident with menstruation (3) Slight stenosis as shown by the passage of the sound, dysmenorrhœa and sterility existing without other cause (4) Mild endometritis from acquired narrowing of the cervical canal and lack of free drainage for the discharges —*Medical News*, April 3, 1886

Inhalations of Cold Air in Typhoid Fever — Dr Alexander M Sokoloff, searching for some means of intensifying the antipyretic action of cold air, resolved upon undertaking a series of experiments on inhalation—that is, on introducing this cooling agent into the lungs, into "one of the regions of maximal heat-formation" His observations were made in twenty-three cases of enteric fever, five of which were of an abortive type, the remaining eighteen being moderately or very severe (two ended fatally) The patients were made to inhale from a Niemeyer's cold air inhaler (*see* P Niemeyer's *Aertzl Spretchs*, vol vi, part 3, p 129), slightly modified by the author About 510 inhalations were made in twenty-three cases, the number of sittings in an individual case varying from six to forty-two, the number of sittings daily from one to three, the duration of a sitting from five to thirty minutes, and the temperature of the air from -2° to 10° R From these observations the author draws the following conclusions

1 Inhalations of cold air produce a greater or less depression of febrile temperature, but, contrary to the author's expectations, their effect is comparatively weaker and more fleeting than that of cold water baths, and even of cold air baths The antipyretic effect of the inhalations varies according to certain conditions (*a*) *The time of the day* The least decrease of the febrile temperature, varying from 0° 2 to 0° 5 C, is observed when the inhalations are made between noon and 6 P M The strongest effect, varying from 0° 5 to 1° 3 C (after a single sitting), is observed between 7 P M and 10 P M (*b*) *The stage of the disease* The slightest and shortest effects are observed during the two first weeks of enteric fever, when the average daily decrease (after several sittings) falls short of 1° C, and when the effect of an individual sitting does not last longer than one and one-half to two hours During the next weeks of the disease the effects are stronger (often 1° C, after a sitting), and last several hours (*c*) *The duration of the inhalation* is but of slight importance A sitting of five to ten minutes' duration gives the same decrease of the febrile temperature as a sitting of twenty minutes' duration [The author attempts to explain this rather strange circumstance by fatigue of the lungs, in consequence of which the patient makes accelerated and superficial respiratory movements] At all events, the greatest antipyretic effects are obtained from sittings of twelve to fifteen minutes' duration (*d*) *The temperature of the air inhaled* A temperature of -2° or -3° R gives almost the same decrease of the febrile temperature as the temperature of -4°, -5°, or -6° R Relatively stronger effects are obtained from temperatures of -8°, -9°, -10° R. [It would seem natural to expect *a priori* that the antipyretic effect ought to be greater, the lower is the temperature inhaled It proved, however, otherwise The relatively small effect of lower temperatures is attributed by the author to a comparatively shorter duration of the sittings, the patients being unable to

perform prolonged inhalations on account of unbearable toothache occurring in consequence of intense cooling of the mouth and teeth] (*e*) *The mental state of the patient* Both depression and excitement (often observed in typhus patients) diminish or even entirely suppress the antipyretic effect of the inhalations

2 The inhalations produce retardation of respiration (in average, four a minute) and pulse (in average, six beats a minute) At the same time, breathing becomes deeper, and the pulse fuller

3 The inhalations relieve dryness of the mucous membranes and skin

4 Inhalations of cold air promote resolution of the bronchitis which often complicates enteric fever, and increase the process of ventilation in the lungs

5 Hence the inhalations lead to an improvement in the patient's general state, sleep, and appetite

6 Inhalations of cold air act antiphlogistically on the inflamed respiratory tracts, and hence may be employed as a rational therapeutic agent in the treatment of pulmonary inflammation

7 Systematic inhalations of cold air may prove of use also in chronic bronchitis, asthma, and emphysema

[In the *Meditzinskoie Obozrenie*, No 13, 1884, p 12, Dr V F Sprimon points to the disadvantage of the use of the cumbrous and heavy Niemeyer's inhaler, and advises a trial, in winter time, of inhalations of cold air conduced from a window through a piece of tubing, the patient inhaling the air by means of a mouthpiece from a Waldenburg's apparatus In the *Vratch*, No 14, 1884, p 242, Professor V A Manassein points out that Sokoloff's observations are important as a new illustration of the fact that cool air in itself is harmless to the febrile patient, and that the well known fears entertained as yet by the public at large, and even by medical men, in regard to "chilling the patient" are entirely groundless Like Sprimon, Manassein also finds any special cooling apparatus superfluous Valuable information is collected in Dr R Neale's *Medical Digest*, sect 257 2 —*Rep*]—*London Medical Record*, March 15, 1886

EXPERIMENTAL TRANSFUSION —It is now generally recognized that many of the conditions in which the operation of transfusion of blood has been regarded as essential, may be successfully treated in other ways Thus it is admitted that the collapse following severe hæmorrhage is due not to a loss of blood *per se*, but to a purely quantitive loss of fluid vascular contents —a loss which may be supplied by the intravenous injection of salt solution Nevertheless, in spite of its dangers, occasions arise in which transfusion is indicated, and in view of the growing disfavor with which the operation is now regarded, much interest attaches to some recent experiments of Bizzozero and Sanquirico, recorded in the ninth volume of the *Arch per le Scienza Med*

In the dogs which were the subjects of these experiments, both the numerical proportion of the red corpuscles and the percentage of hæmoglobin were first ascertained Blood in varying amounts was then withdrawn, and an equal quantity of defibrinated dog's blood transfused by the jugular vein In periods of from fifteen minutes to eighteen days the blood of animals thus operated upon was investigated, and the results compared with those of the preliminary examination In a second series of experiments, one-half of the total blood of the animals was withdrawn, defibrinated, filtered through linen and returned to the veins of the animals from which it was taken This procedure was ten times repeated, so that each corpuscle of the animal was subjected approximately five times to this rough handling Before and after this series of experiments the same close examination of the quantitative relations of corpuscles and hæmoglobin was instituted, with the result of showing that in no case, in either series was a noteworthy effect produced

These observations lead to the conclusion that not only is the red corpuscle remarkably resistant to rough treatment, but that the transfusion of the defibrinated blood of animals of the same species is not injurious —*Medical News*, April 3, 1886

PHYSIOLOGICAL ACTION OF ANTIPYRIN AND KAIRIN —DR S J PAVLINOFF describes the results of some experiments as to the chemical and physiological properties of antipyrin and kairin

Chemical Properties —[The preparation of antipyrin was obtained from Ferrein, and presented an amorphous yellowish powder of pretty strong bitter taste, with aromatic flavor It was soluble in water and ether, the solutions were neutral] Kairin belongs to light oxydizable substances, its solutions, kept in contact with the air, within twelve hours become of a ruby color, and in a few days rich dark cherry red On the other hand, solutions of antipyrin remain unchanged (that is, either colorless or yellowish) for a month, or even longer Being treated by nitric acid, kairin solutions turn to dark cherry-red, and, on being subsequently diluted, they gradually become yellow, the latter coloration occurring still even when only 0 001 per cent of the drug is present Antipyrin gives no reaction with the acid But both kairin and antipyrin solutions assume a claret red color on being treated by perchloride of iron ($Fe_2 Cl_6$)

Physiological Action —A *Blood* —As Morokhovetz showed (see the *London Medical Record*, October, 1884, p 421), when mixed with an equal volume of a 0 001 per cent solution of kairin, the blood assumes a claret red color, and gives the methæmoglobin bands on the spectroscopic examination The red blood corpuscles take a cup-like form and brownish color But antipyrin remains entirely inactive, even when a 1 per cent solution is employed The same difference between the two substances is observed, also, when intravenous injections of their solutions in dogs are undertaken B *Blood pressure* —Antipyrin induces an increase of the arterial tension, while the latter is rapidly and very considerably lowered by kairin (after a fleeting initial rise) C *Pulse*—Under antipyrin, the pulse becomes somewhat retarded, but its rhythm remains regular, while under kairin it quickens and assumes a filiform character Some experiments seem to point out that kairin affects the cardiac muscle, the cardiac nerve-apparatus remaining intact On the contrary, antipyrin appears to act on the latter, and to leave intact the former *Respiration* —Antipyrin produces a very considerable quickening of the respiration, the type of which, however, remains uniform all through On the other hand, kairin brings about interrupted or irregular breathing [Therefore, as far as circulation and respiration are concerned, kairin and antipyrin are endowed with diametrically opposite actions] E *Salivary Glands* —Both of the drugs augment the secretion of saliva, antipyrin may be detected after a while in the latter, though in small quantities F *Pancreas* —Neither antipyrin nor kairin has any influence on the secretion of pancreatic juice G *Liver* —Kairin increases the secretion of bile, the color of which gradually turns to black, while antipyrin remains entirely inactive H *Kidneys* —Neither of the drugs manifests any action on the quantity of urine But the first portions of urine voided after the introduction of antipyrin contain a considerable quantity of the drug [Therefore, antipyrin is eliminated from the system through the kidneys and salivary glands] I *Motor Nerves* Dr Pavlinoff confirms the statement of Morokhovetz that kairin, like curare, affects the intramuscular endings of the motor nerves (in frogs), the drug acts antagonistically to strychnine (as Professor F P Sheremetevsky supposed) Nothing of the kind is noted as regards antipyrin J *Reflex Action* —Antipyrin increases the reflex action (as Professor Demme, of Berne, first proved) K *Temperature* Antipyrin depresses the normal temperature, but not at any uniform rate, the latter varying from 0° 5 to 2° C and more, generally speaking, the depression is the more marked, the shorter are the intervals between the doses administered Under kairin, the temperature sinks in consequence of the drug absorbing oxygen of the blood, hence, the use of karin in cases of pneumonia, chronic pulmonary disease, anæmia, cardiac disease, etc, is fraught with obvious and immediate danger In all such cases, antipyrin may be safely and effectively administered, the drug being indifferent in its chemical behavior towards the blood, and if anything, strengthening the cardiac action —*London Medical Record*, March 15, 1886 -

Decoction of Lemons in Intermittent Fever —Having reviewed the literature of the subject (Maglieri, Stephens, Toropoff, Tommasi Crudeli, Dominico Azzillo, Norman Forbes, Lauchlan Aitken, Putokhin), Dr Nikolai N Maslenikoff proceeds (*Kavkazsky Meditz Sbornik*, vol 39, Fasc ii, 1885, p 29) to describe his own observations on twenty cases of intermittent fever, treated by decoction of lemons in the Military Hospital in Temir Khan Shura Dagestan region Seven of the patients were affected by the fever for the first time, three for a second, the remaining had passed previously through several malarial attacks In thirteen of twenty cases a quotidian, and in seven a tertian, variety was present In sixteen cases the spleen was found to be enlarged and painful (in fourteen, both during the paroxysms and the intervals) The decoction was prepared after Maglieri's method, that is, every evening a whole fresh lemon was cut into very thin slices, put into eighteen ounces of distilled water in an earthen pot, and boiled (for two hours) until six ounces of decoction remained On the next morning the liquid was forcibly strained through a piece of gauze, and then given to the patient to take immediately at several gulps The decoction was used in that way for ten or fourteen successive days In none of the patients did any gastric disturbances occur The results obtained by Dr Maslennikoff were not so successful as those by Dr Putokhin In only six cases, four of which were of quotidian fever and two of tertian, a cessation of paroxysms ensued In two of the remaining patients, the paroxysms became less severe, and in three the type of fever underwent a change In none did any alterations in size of the spleen take place All cases where decoction of lemons had failed were subsequently, mostly very rapidly, cured by quinine The general conclusion reached by the author is that, as far as severe Caucasian fevers are concerned, decoction of lemons has, except its agreeable taste and harmlessness, no advantages whatever over other substitutes for quinine —*London Medical Record*, March 15 1886

Hepatic Origin of Urea —Dr D W Aitken, describes, in the *British Medical Journal* of February 6, 1886, the following interesting case, the direct bearing of which upon the question of the source of urea is evident

Early this month (January) I was called to see a boy who had the day previous received a rather severe blow upon the right lobe of the liver When seen he was complaining of much pain in the right hypochondrium The skin was slightly, and the conjunctiva distinctly jaundiced The stools were pale, while the urine was bile colored, and gave the bile reaction with nitric acid, there was no fever But herein lies the important matter The urine was highly alkaline On the addition of nitric acid there was such violent effervescence that the froth was forced out of the test-tube, although the urine was not much more than one inch deep I got my friend, Dr Drinkwater, to examine the urine carefully He reports that the alkalinity was due to ammonium carbonate, and, on estimating the urea, he found only three per cent

This evidence seems to point strongly to the liver as the seat of production of urea Dr Graves has already reported several cases of absence of urea which he believed to be represented in the urine by the ammonium carbonate, but here we have a history of the organ involved — *Medical News*, April 3, 1886

A Micro organism in the Tissues of Heredito-syphilitic Children —Kassowitz and Hochsinger have found micro organisms constantly in five syphilitic children, occurring in the skin in pemphigus, in the liver, and in bone tissue They are streptococci, arranged in chains The authors have never found Lustgarten's bacilli The micro organisms found occurred in the fine capillaries —*St Petersb Med Woch*, No 11, 1886

SATURDAY, APRIL 17, 1886

IN WHAT PLACES SHOULD THE ANNUAL MEETINGS OF THE AMERICAN MEDICAL ASSOCIATION BE HELD, AND WHAT ARE THE NECESSARY LOCAL EXPENSES CONNECTED WITH SUCH MEETINGS?

These are questions of sufficient importance to demand more attention than they have hitherto received To prevent the membership and the influence of the Association becoming too much restricted within narrow limits, and to secure the stimulating influence of these meetings upon the formation and support of State and local societies in all parts of the country, a constitutional provision was adopted prohibiting the holding of two annual meetings in succession in the same place Consequently the general policy has been to have the annual meetings alternate from one section of the country to another, depending much upon such invitations as might be extended by the local profession in different cities While the leading objects sought to be accomplished by holding the meetings in different parts of the country were actually attained, and the social organization of the profession in the different States was rapidly advanced, some evils were developed which have never been obviated

It was found that the income of the Association was made to depend much upon the size and location of the city in which the meetings were held When a meeting was held in any of the great cities surrounded by States in which the profession was well organized, the number in attendance was large, and the income from the payment of membership dues was correspondingly large, but when the meeting occurred in a smaller city, or even in a large city not surrounded by populous States in which the profession was well organized, the number was small and the income small For although the annual membership fee was due from all permanent members whether attending the annual meetings or not, yet the Treasurer's reports show that comparatively little was actually paid except at these meetings While the Transactions of the Association were published in a single volume yearly and distributed from six to nine months after each meeting, the amount actually collected from permanent members not at the meetings was so small that the number losing their membership from non-payment of their dues came to be nearly equal to the annual addition of new members

Since, instead of one annual volume, each member receives a valuable medical journal each week, the financial evils just mentioned have greatly lessened and the annual income from membership dues has doubled And yet so apparent are the advantages of a meeting in a large city in the centre of populous States and well organized State Societies, both in securing the addition of new members and larger revenues, that careful attention should be given to the subject by each nominating committee Another evil of greater magnitude developed early and increased rapidly in connection with the practice of meeting successively in different sections and on direct invitations from the profession of different cities in which the meetings were held Naturally, when the profession of a city extended an invitation to the Association to hold the next annual meeting there, they assumed the responsibility of furnishing all necessary accommodations for the meeting at their own expense, as well as the additional expense of what hospitalities in the way of banquets, entertainments, etc , might be provided

At the first two or three annual meetings the hospitalities were cordial, but of a private or individual character But at the third annual meeting, which was held at Boston, in 1849, one evening was set apart for a general social melee or promenade in a public hall for the laudable purpose of affording more direct social intercourse of members from all parts of the country With genuine good taste the local committee provided no other refreshments than coffee, simple cakes and fruit, on a side table where any one who wished could partake when they pleased But this simple and very pleasant example was quickly converted into the form of a "public banquet" which each subsequent local Committee of Arrangements endeavored to make more *magnificent and costly* than their predecessors, until at New York, in 1853, the banquet alone was said to have cost more than the latter, and to leave intact the former *Respiration*—Antipyrin produces a very considerable quickening of the respiration, the type of which, however, remains uniform all through On the other hand, kairin brings about interrupted or irregular breathing [Therefore, as far as circulation and respiration are concerned, kairin and antipyrin are endowed with diametrically opposite actions] E *Salivary Glands*—Both of the drugs augment the secretion of saliva, antipyrin may be detected after a while in the latter, though in small quantities F *Pancreas*—Neither antipyrin nor kairin has any influence on the secretion of pancreatic juice G *Liver*—Kairin increases the secretion of bile, the color of which gradually turns to black, while antipyrin remains entirely inactive H *Kidneys*—Neither of the drugs manifests any action on the quantity of urine But the first portions of urine voided after the introduction of antipyrin contain a considerable quantity of the drug [Therefore, antipyrin is eliminated from the system through the kidneys and salivary glands] I *Motor Nerves* Dr Pavlinoff confirms the statement of Morokhovetz that kairin, like curare, affects the intramuscular endings of the motor nerves (in frogs), the drug acts antagonistically to strychnine (as Professor F P Sheremetevsky supposed) Nothing of the kind is noted as regards antipyrin J *Reflex Action*—Antipyrin increases the reflex action (as Professor Demme, of Berne, first proved) K *Temperature* Antipyrin depresses the normal temperature, but not at any uniform rate, the latter varying from 0° 5 to 2° C and more, generally speaking, the depression is the more marked, the shorter are the intervals between the doses administered Under kairin, the temperature sinks in consequence of the drug absorbing oxygen of the blood, hence, the use of kairin in cases of pneumonia, chronic pulmonary disease, anæmia, cardiac disease, etc, is fraught with obvious and immediate danger In all such cases, antipyrin may be safely and effectively administered, the drug being indifferent in its chemical behavior towards the blood and if anything, strengthening the cardiac action —*London Medical Record*, March 15, 1886

DECOCTION OF LEMONS IN INTERMITTENT FEVER —Having reviewed the literature of the subject (Maglieri, Stephens, Toropoff, Tommasi Crudeli, Domenico Azzillo, Norman Forbes, Lauchlan Aitken, Putokhin), DR NIKOLAI N MASLENIKOFF proceeds (*Kavkazsly Meditz Sbornil*, vol 39, Fasc 11, 1885, p 29) to describe his own observations on twenty cases of intermittent fever, treated by decoction of lemons in the Military Hospital in Temir Khan Shura Dagestan region Seven of the patients were affected by the fever for the first time, three for a second, the remaining had passed previously through several malarial attacks In thirteen of twenty cases a quotidian, and in seven a tertian, variety was present In sixteen cases the spleen was found to be enlarged and painful (in fourteen, both during the paroxysms and the intervals) The decoction was prepared after Maglieri's method, that is, every evening a whole fresh lemon was cut into very thin slices, put into eighteen ounces of distilled water in an earthen pot, and boiled (for two hours) until six ounces of decoction remained On the next morning the liquid was forcibly strained through a piece of gauze, and then given to the patient to take immediately at several gulps The decoction was used in that way for ten or fourteen successive days In none of the patients did any gastric disturbances occur The results obtained by Dr Maslennikoff were not so successful as those by Dr Putokhin In only six cases, four of which were of quotidian fever and two of tertian, a cessation of paroxysms ensued In two of the remaining patients, the paroxysms became less severe, and in three the type of fever underwent a change In none did any alterations in size of the spleen take place All cases where decoction of lemons had failed were subsequently, mostly very rapidly, cured by quinine The general conclusion reached by the author is that, as far as severe Caucasian fevers are concerned, decoction of lemons has, except its agreeable taste and harmlessness, no advantages whatever over other substitutes for quinine —*London Medical Record*, March 15 1886

HEPATIC ORIGIN OF UREA —DR D W AITKEN, describes, in the *British Medical Journal* of February 6, 1886, the following interesting case, the direct bearing of which upon the question of the source of urea is evident

Early this month (January) I was called to see a boy who had the day previous received a rather severe blow upon the right lobe of the liver When seen he was complaining of much pain in the right hypochondrium The skin was slightly, and the conjunctiva distinctly jaundiced The stools were pale, while the urine was bile colored, and gave the bile reaction with nitric acid, there was no fever But herein lies the important matter The urine was highly alkaline On the addition of nitric acid there was such violent effervescence that the froth was forced out of the test-tube, although the urine was not much more than one inch deep I got my friend, Dr Drinkwater, to examine the urine carefully He reports that the alkalinity was due to ammonium carbonate, and, on estimating the urea, he found only three per cent

This evidence seems to point strongly to the liver as the seat of production of urea Dr Graves has already reported several cases of absence of urea which he believed to be represented in the urine by the ammonium carbonate, but here we have a history of the organ involved —*Medical News*, April 3, 1886

A MICRO ORGANISM IN THE TISSUES OF HEREDITO-SYPHILITIC CHILDREN —KASSOWITZ and HOCHSINGER have found micro organisms constantly in five syphilitic children, occurring in the skin in pemphigus, in the liver, and in bone tissue They are streptococci, arranged in chains The authors have never found Lustgarten's bacilli The micro organisms found occurred in the fine capillaries —*St Petersb Med Woch*, No 11, 1886

Address
JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No 65 RANDOLPH STREET
CHICAGO, ILLINOIS

SATURDAY, APRIL 17, 1886

IN WHAT PLACES SHOULD THE ANNUAL MEETINGS OF THE AMERICAN MEDICAL ASSOCIATION BE HELD, AND WHAT ARE THE NECESSARY LOCAL EXPENSES CONNECTED WITH SUCH MEETINGS?

These are questions of sufficient importance to demand more attention than they have hitherto received. To prevent the membership and the influence of the Association becoming too much restricted within narrow limits, and to secure the stimulating influence of these meetings upon the formation and support of State and local societies in all parts of the country, a constitutional provision was adopted prohibiting the holding of two annual meetings in succession in the same place. Consequently the general policy has been to have the annual meetings alternate from one section of the country to another, depending much upon such invitations as might be extended by the local profession in different cities. While the leading objects sought to be accomplished by holding the meetings in different parts of the country were actually attained, and the social organization of the profession in the different States was rapidly advanced, some evils were developed which have never been obviated.

It was found that the income of the Association was made to depend much upon the size and location of the city in which the meetings were held. When a meeting was held in any of the great cities surrounded by States in which the profession was well organized, the number in attendance was large, and the income from the payment of membership dues was correspondingly large, but when the meeting occurred in a smaller city, or even in a large city not surrounded by populous States in which the profession was well organized, the number was small and the income small. For although the annual membership fee was due from all permanent members whether attending the annual meetings or not, yet the Treasurer's reports show that comparatively little was actually paid except at these meetings. While the Transactions of the Association were published in a single volume yearly and distributed from six to nine months after each meeting, the amount actually collected from permanent members not at the meetings was so small that the number losing their membership from non-payment of their dues came to be nearly equal to the annual addition of new members.

Since, instead of one annual volume, each member receives a valuable medical journal each week, the financial evils just mentioned have greatly lessened and the annual income from membership dues has doubled. And yet so apparent are the advantages of a meeting in a large city in the centre of populous States and well organized State Societies, both in securing the addition of new members and larger revenues, that careful attention should be given to the subject by each nominating committee. Another evil of greater magnitude developed early and increased rapidly in connection with the practice of meeting successively in different sections and on direct invitations from the profession of different cities in which the meetings were held. Naturally, when the profession of a city extended an invitation to the Association to hold the next annual meeting there, they assumed the responsibility of furnishing all necessary accommodations for the meeting at their own expense, as well as the additional expense of what hospitalities in the way of banquets, entertainments, etc., might be provided.

At the first two or three annual meetings the hospitalities were cordial, but of a private or individual character. But at the third annual meeting, which was held at Boston, in 1849, one evening was set apart for a general social melee or promenade in a public hall for the laudable purpose of affording more direct social intercourse of members from all parts of the country. With genuine good taste the local committee provided no other refreshments than coffee, simple cakes and fruit, on a side table where any one who wished could partake when they pleased. But this simple and very pleasant example was quickly converted into the form of a "public banquet" which each subsequent local Committee of Arrangements endeavored to make more magnificent and costly than their predecessors, until at New York, in 1853, the banquet alone was said to have cost more than

$10,000, and the next year at St. Louis its extravagance and the excesses accompanying it, led to the adoption of a resolution offered by the late Professor S. D. Gross, forbidding all subsequent Committees of Arrangements to provide any public banquet in connection with the annual meetings of the Association. This checked the evil in that direction, and still the rule was often evaded by accepting banquets tendered in the name of the citizens instead of the local profession, and costly entertainments and private receptions multiplied, not only sufficient to constitute a heavy tax upon the local profession, but also to so completely occupy all the time intervening between the necessary sessions of the Association and the Sections, as to leave hardly an hour for special committees to do any work that might be assigned to them, or for fatigued members to obtain a much needed rest.

It was to still further lessen these evils, that in 1867 a rule was adopted that each alternate annual meeting should be in Washington, the Capital of the country, and the strictly necessary expenses for rooms to accommodate both the general sessions and the Sections, and the printing of programmes for all future meetings, should be paid from the treasury of the Association, thus relieving the local profession from all strictly necessary expenses for the annual meetings. Nevertheless, wherever an invitation has been accepted to meet in any city, the parties giving the invitation have continued the practice of filling every evening with an excess of expensive entertainments or receptions, and sometimes crowding excursions into a part of the last day of the meeting. We think the time has come when reliance upon invitations to meet in one city or another should be abandoned and the selections should be made with reference to securing the largest increase in the membership, and as far as possible strengthening the State and local organizations in all parts of the country. Inasmuch as the Association pays for all the necessary accommodations and printing for each meeting, there should be no direct or implied money tax on the local profession at the place of meeting, but only the services of an efficient Committee of Arrangements. In all the great cities there are wealthy citizens both in and out of the profession who would deem it a pleasure to give receptions enough to occupy one evening, and if any considerable number of the members of the Association desire a social dinner or banquet, it should be provided at their own expense and under their own supervision, as is the case in the British Medical Association and in similar organizations in other countries.

MOOT POINTS IN SYPHILIS.

When, a few months ago, it was announced that MR. JONATHAN HUTCHINSON, the Lettsomian Lecturer of the Medical Society of London, for 1886, would lecture on "Some Moot Points in the Natural History of Syphilis," dermatologists, syphilographers and surgeons generally were on the *qui vive* to see how the subject would be treated by the generally acknowledged master pathologist and surgeon. American surgeons and dualists were quite prepared for an opening shot at dualism, but few, we think, were prepared to read the following: "A dualist is, I suppose, one who holds that there exist two quite distinct and independent cartagia, one of which produces a non-infecting sore, and the other syphilis." Under the circumstances of place and subject it seems that the lecturer should at least have been entirely familiar with the ground of the "the opposition," the more especially since in the next breath he begins to discuss the question at issue.

Beginning with a series of hypotheses, and a play upon words as to the difference between "specific contagium and specialized contagium," the lecturer built up a very pretty argument in favor of unicity—but one in which the facts of Basserau, Diday, Rollet, Fournier, Coby, Ricord and, not to make the list too long, Pick, Kraus, Reder, Henry Lee and Morgan (quoted by Mr. Hutchinson in support of unicity), Wigglesworth and R. W. Taylor are to all appearances utterly ignored. Equally surprising is the fact that so good a pathologist and so close a student seemingly forgets the pathological differences between the chancre and the chancroid. Can it be that the "specific contagium" of the one produces cell proliferation, while the "specialized contagium" of the other causes distinctive metamorphosis? In the face of the mass of evidence to the contrary Mr. Hutchinson says: "So far as I can see, all *a priori* probability favors the suggestion that non-indurated sores are produced by the secretion of true chancres, which have been changed in character either by the inflammatory process, or by the non-susceptibility of the tissues of the recipient." In that portion of his first lecture in which he discusses this question the only names mentioned are those of Danielson, Lee, Morgan, Gascoyen and Bidencap. The conclusion of Baumler that "the chancroidal poison cannot even be compared with the syphilitic poison, to say nothing of regarding them as identical," appears to have escaped notice.

Few surgeons in this country or on the Continent, we think, will agree that "scars in the groin are presumptive evidence of syphilis." We must know how the patient was treated for the sore which preceded the bubo, and whether, as is sometimes the case with chancroidal buboes, the glandular trouble appeared after the primary sore disappeared But apart from this Mr Hutchinson is certainly at variance with authorities in holding this view The best authorities are agreed that the syphilitic bubo usually terminates by resolution, while the chancroidal is inclined to suppuration There is, therefore nothing remarkable in Mr Hutchinson's experience of having never seen a suppurated bubo in the armpit in association with chancre of the finger We neither see anything remarkable in this fact, nor can we agree with him that it indicates that the "soft sore but rarely causes bubo"—an inference which he draws If it be his observation that "it is not very exceptional for the typical chancroid to cause no enlargement of the glands at all" his experience must be exceptional, and broad general deductions should not be drawn from such an experience With such views as to the nature and pathology of the chancroid we are prepared for an announcement that phagadæna is as frequent a sequence of chancre as of chancroid, but scarcely for the sweeping statement that "all will admit that syphilitic inflammations have a remarkable tendency to become phagodænic," unless the chancroid be classed as a syphilitic inflammation Nevertheless, within a page of the statement just quoted he says that it is a question whether the infecting or the non infecting sore is the more liable to phagadæna

We can agree with the lecturer that too much importance has been attached to induration of the chancre as a symptom of syphilis Induration may be entirely absent, or it may vary widely in degree and duration Chancrous induration is not altogether so common, in the opinion of the best authorities, as glandular induration Mr Hutchinson thinks, however, that we must therefore come to the conclusion that "syphilis can begin without any induration whatever" He does not think it very probable that an intra urethral chancre may occur without pain, without signs of obstruction, and without external induration or discharge, but this is certainly as probable, if not more so, than that syphilis can be introduced into the system without any abrasion In connection with such cases he refers to those in which a patient has a urethral discharge, simulating gonorrhœa, or gonorrhœa itself, and in which syphilis, without the detection of a chancre, follows We cannot believe that there is any good reason for terming such cases "gonorrhœa-syphilis" because the affections are at first coincident It should be remembered that the urethral discharge is by no means necessarily gonorrhœal In a case of true gonorrhœa, as Mr Hutchinson suggests, the acute urethral inflammation may act in preventing the local adhesive inflammation of the chancroid, and this is a much more tenable hypothesis than that the syphilitic virus is absorbed directly, without any sore at all

We may pass over the remarks on rupia and psoriasis palmaris, syphilitic lupus, periostitis and other symptoms commonly classed as tertiary, but which are not strictly confined to that period, and notice what the lecturer has to say of the influence of mercury as antidote His remarks on this subject should be read by every one who is partial to large doses of this drug in the treatment of syphilis Indeed, since we know that small doses of mercury increase the number of red blood corpuscles, and that large doses diminish the number, it seems strange that anyone should now advocate or administer large doses Recent experience, says Mr Hutchinson, has much strengthened the claim of mercury to rank as an antidote to the virus of syphilis, and the fact is "one of extreme importance in reference to a very important department of general pathology and therapeutics In connection with it we may suitably bear in mind the great repute which weak solutions of corrosive sublimate have recently obtained in the prevention of septic processes" The form of mercury which he has used almost exclusively is the gray powder, in one grain doses, from three to six times in twenty-four hours, and seldom for a shorter time than six months in the first instance "If this dose be given to a patient with an indurated sore, but in whom, as yet, no secondary symptoms have appeared, the result will usually be that none will occur" Neither the preparation of mercury used nor the time of giving it will be endorsed, we think, by the majority of syphilographers, The weight of authority is certainly against the administration of the drug before the appearance of constitutional symptoms (save in exceptional cases) Otherwise it is entirely probable that a patient may take it for some months, and have much mental anxiety, when he has only had a chancroid He admits that the grey powder is the "most convenient" form, but syphilis is a disease in which we cannot always consult our convenience The evidence seems entirely sufficient to show that the course of a case is not affected by delaying the mercurial treatment until constitutional symptoms appear

The third lecture is devoted entirely to questions concerning the inheritance of syphilis, and it is in this particular field that Mr Hutchinson has done some most excellent work The points discussed in the lecture are as to transmission to many children in succession, the supposed connection between syphilis and rickets, ulcers of the palate and pharynx in young persons, malformation of joints in consequence of infantile syphilitic periostitis, ringworm of the tongue, possibly sometimes connected with hereditary syphilis, chronic skin diseases due to hereditary syphilis, diseases of the nervous system, and idiocy in connection with inherited syphilis As already stated, his work in the way of elucidating problems in hereditary syphilis is monumental, as may be seen in the almost unparalleled article on "Hereditary Syphilis," by Dr J William White, in Pepper's "System of American Medicine " We could wish that much more time could have been given by Mr Hutchinson to the questions discussed in the third lecture A full discussion of these questions could very properly have taken up two lectures, especially had those spoken of in the first been omitted altogether

ARTIFICIAL RESPIRATION AND STILLBIRTH

In the *American Journal of the Medical Sciences*, for January, 1886, Mr Francis Henry Champneys, of London, has a most instructive article "On Some Points in the Practice of Artificial Respiration in Cases of Stillbirth and of Apparent Death after Tracheotomy " Before entering into a consideration of the subject proper, however, he rightly draws attention to the fact that "deadbirth" and "stillbirth" are not synonymous, for while all deadborn children are stillborn, all stillborn children are not deadborn "A child born alive but 'still'—that is, generally, but not necessarily, with its heart beating, but without movement—may be in one of two stages or states, for the description of which we are indebted to Cazeaux In the first, which he calls the 'apoplectic state,' the surface is livid, but the muscular tone is not lost, and there is no response to reflex irritation In the second, which he calls 'syncope,' the surface is pale, the muscular tone is lost, and there is no response to reflex irritation These two stages are also known as the livid stage and the pale or flabby stage of asphyxia "

The length of time which apparently dead children sometimes survive is remarkable, and the authenticated cases show that the greatest caution should be used to guard against premature burial or autopsy The prognosis in cases of stillbirth, says Mr Champneys, is of the utmost importance as a guide to treatment, but is usually not made "The certainty of death in the cases of fresh children depends on the certainty of the cessation of the heart's action during a considerable period, for the heart may cease to beat for a time, apart from absolute death In such a case, when the heart has ceased to beat for a considerable time (say ten to fifteen minutes), it might be well cautiously to insert a needle into its apex, before abandoning all efforts at resuscitation " As regards how long attempts at resuscitation should be persisted in on the sole ground of continued action of the heart, he thinks that if no attempts at spontaneous breathing occur within an hour, and especially if the heart act with diminishing force and frequency, in spite of the attempts at artificial respiration, the prognosis is hopeless Upon the diagnosis of the state of asphyxia depends the second point in the prognosis, it being usually favorable in the livid stage, as this stage has the advantage of retaining reflex irritability "If the heart is beating fairly, it is often sufficient to lay the child on its face, wipe out its mouth, and rub it along the spine, a far better way of exciting an inspiration than slapping the nates " But the prognosis is far more serious in the pale or flabby stage, and depends on the ability of the accoucheur to raise the child from the condition of flabbiness and induce a condition of reflex irritability "Until this is done, all rubbing, slapping, bathing, etc , are simple waste of time While the heart beats regularly, we may still hope for recovery up to a reasonable length of time An important element in prognosis is the state of the pupils they are widely dilated in asphyxia, but at once contract when respiration is properly established

En passant Mr Champneys has a word for those who tie the cord early "It appears that a child gains some four to six ounces of blood after birth, the principal object of which is probably to furnish an additional supply for the newly established pulmonary circulation, This blood is not forced into its body so much as drawn into it by the first inspiration In ordinary cases, therefore, it is best to tie the cord late unless manipulations are indicated which require the child to be free from its mother " The usual advice that half an ounce or an ounce of blood should be allowed to escape from the cord in cases of livid asphyxia is probably founded on the livid appearance of the child "The child, however, has *less* blood than it should eventually have, and has no more than a child in the pale stage, the difference being one in the distribution rather than the amount of blood "

In artificial respiration four objects are aimed at removal of foreign bodies from the air-passages, procuring the patency of the air passages, excitation of the circulation, ventilation of the lungs The best method of removing foreign bodies from the air-passages is, according to our author, the following Lay the child on its back, with the head hanging over the edge of a table, a little lower than the rest of its body Wipe out the mouth with a soft handkerchief Press the thorax gently with one hand, stroking the trachea upwards with the other, and retain the finger at the top of the trachea until the next movement is complete The mucus will gravitate towards the posterior nares Put a handkerchief over the child's mouth, blow gently, and the mucus will be blown out of the nostrils, but not into the operator's face Should there be a large accumulation of mucus in the air passages, a No 9 elastic male catheter should be introduced into the trachea, so that the point is three and a half inches from the lips, which will secure its passage through the glottis, but not to the bifurcation of the trachea Press the thorax gently with one hand to prevent the entrance of air, and blow through the catheter In this way the mucus will be blown into the pharynx, as the compression of the thorax with the hand prevents it being carried into the lungs "This manœuvre is more efficient and far pleasanter than the suction usually recommended, it has answered well in practice "

For securing patency of the air passages, exciting the circulation, and ventilating the lungs, Mr Champneys thinks that Schultze's methods of artificial respiration accomplish them better than anything else (though for exciting the circulation pressure of the hand over the præcordium has an effect in raising the blood pressure and exciting the action of the heart, and is a chief reason for the success of the methods of Howard and Hall) The only two trustworthy methods for ventilating the lungs are those of Schultze and of Silvester (with the modifications of the latter by Pacini and Bain) As these methods and modifications have been known for more than a decade it seems unnecessary to give them in detail in this place Silvester's method does not imitate the natural breathing of the child, which is diaphragmatic, while in Schultze's methods the diaphragm is made to descend slightly Though his method has the disadvantage of being somewhat more violent than the others (which can be in a measure controlled by the operator), it has the two advantages that in the expiratory position the child is inverted, and gravity assists in removing mucus and other substances from the air passages, and that in some cases it really provides patency of the air-passages when other methods have failed In case it be desired to practise direct inflation of the lungs, the operation may be made clean by laying a towel over the child's mouth and breathing through it The asserted danger of rupturing the lungs may be averted by gentleness and leaving the nose free The imaginary danger of inflating the stomach need not be discussed

As regards the action of heat and cold Mr Champneys has but little to say, but that little is entirely to the point "It has been proved that, within limits, the lower the temperature the longer can an animal survive without breathing, and the higher the temperature the more quickly it dies To keep a child in a hot bath until respiration is established is, therefore, a wrong practice The hot bath can, however, be used in alternation with the cold bath, but merely as a means of increasing the effect of the cold bath, and in the pale (flabby) stage of asphyxia this also is useless Under such circumstances it is best to wrap the child in a warm flannel, and not to waste time on baths, but to proceed at once to the establishment of respiration " The treatment advocated in this admirable paper is summed up as follows Never hurry, it is not a question of seconds, and success depends upon a fine exercise of the judgment Make a good diagnosis, first, as to life or death, second as to the stage of asphyxia (if life is not extinct) If the child be macerated, it is obviously dead and past hope If the heart beat, ever so slowly and feebly, it is not dead If the heart be not beating, death is not certain, unless it can be proved to be inactive for some time If the child is livid and not flabby, it will probably come round, wipe out its mouth and pharynx, and rub it with a soft cloth down the spine, press gently on the cardiac region If this produces no effect, inflate the lungs by the mouth, and then by Silvester's method If air enter the lungs, well and good, if not, try Schultze's method, or insert a catheter, as described above On the first sign of muscular action, plunge the child into cold water, or into alternate cold and hot baths Vary the treatment between occasional inflation of the lungs, artificial respiration, pressure over the cardiac region, baths, irritation down the spine, according to the judgment, remembering what may be expected of each method, and that no one will suffice for all cases Watch for signs of resuscitation, namely, improvement in the color, in movements, in cardiac pulsations, as described above Never be content until the child breaths regularly, and appears to be continually improving

---

STATE MEDICAL SOCIETY OF ARKANSAS, CHANGE OF PLACE OF MEETING

The president, W H Hawkins, M D, and the secretary, L P Gibson, M D, of the State Medical Society of Arkansas, have sent out the following circular regarding the change of place of meeting of the Society

"On account of the terrific fire and cyclone that have afflicted Helena, and the probability of an overflow cutting off communication with that city about the time of the meeting, the committee of arrangements has given notice that it would be advisable to change the place of meeting Therefore the eleventh annual session of the State Medical Society of Arkansas will be held in the Council Chamber at Little Rock on Wednesday and Thursday, April 28 and 29, 1886, commencing on Wednesday at 10 a m

"It is of the greatest importance that members who intend to read papers will send the titles of the same to the secretary at once, so that a complete programme can be prepared

"Questions of grave importance to the medical profession, not only of Arkansas but of the whole nation will be considered, and every member ought to attend and induce others to come and join the society

"Arrangements have been made for reduction of fare on the railroads"

A BILL FOR AN ACT TO REGULATE THE PRACTICE OF MEDICINE AND SURGERY IN THE STATE OF IOWA has recently passed the Legislature of that State and become a law, though its penalties are not to be enforced until January 1887 The law is similar in many of its features to the well known Illinois law for regulating the practice of medicine and surgery The Bill in full may be found in the department of State Medicine in this week's issue of THE JOURNAL

THE ADDRESS IN MEDICINE BEFORE THE BRITISH MEDICAL ASSOCIATION —It is announced that DR J S BILLINGS, U S A, has been selected to deliver the Address in Medicine before the next meeting of the British Medical Association, in place of the late Professor Austin Flint The well known ability of Dr Billings and his familiarity with general medical literature, makes the selection one eminently proper

DEATH OF A MEDICAL STUDENT —MR GEORGE A COOK, a student of the Chicago Medical College, died April 8, 1886, at the residence of his father, Dr E P Cook, in Mendota, Ill, of pneumonia, aged 21 years He was a good student and a young man of much promise

MEDICAL LEGISLATION IN OHIO —A note from Dr R Harvey Reed, of Mansfield, Ohio, informs us that a Bill establishing a State Board of Health has passed both branches of the Ohio Legislature and become a law We have not as yet any details of the Bill

SOCIETY PROCEEDINGS

SUFFOLK DISTRICT MEDICAL SOCIETY

SECTION FOR CLINICAL MEDICINE, PATHOLOGY AND HYGIENE

Stated Meeting, March 10, 1886

F I KNIGHT, M D, CHAIRMAN

ALBERT N BLODGETT, M D, SECRETARY

The first work of the evening was the presentation of lantern-slides, by DR H O MARCY, containing

PHOTOGRAPHIC VIEWS TAKEN FROM MICROSCOPIC PREPARATIONS OF THE VARIOUS BACTERIAL FORMS FOUND IN THE COMMUNICABLE DISEASES,

as well as a series of preparations showing the impurities contained in the atmosphere, in water, in clothing, etc

DR CUSHING being called upon by the Chairman, remarked that he had nothing to say other than he had recently said before this Society in a paper upon an allied topic One thing is becoming more and more evident, and that is the great and increasing degree of importance which is to be attached to the various forms of bacterial organisms, both as causes of, and factors in, the origin or the course of a large and increasing list of diseases It is an undeniable truth that these lower forms of growth are associated in many ways with the health of the human subject, and the degree of weight to be attached to their presence cannot be overestimated The technical difficulties attending the study of these organisms in their relations to human health have been, and still are, greatly magnified, and the processes of their preparation and preservation made unnecessarily obscure There is no difficulty in the successful study of bacteria, any careful person can fully and completely understand the technique, and easily carry out the details of an examination of the animal tissues or secretions in relation to the presence or absence of disease germs Test tubes may be thoroughly sterilized in the kitchen oven, and a culture chamber may be made from two soup-plates placed one upon the other An even-temperature oven may be made from a wash boiler, and the entire process may be so simplified that any good microscopist may be able to carry it out Septic bacteria are easy to cultivate and to examine As we become familiar with the processes of culture, and realize that a single touch of a needle is sufficient to infect an aseptic culture, we form a better comprehension of the great importance of absolute cleanliness on the part of the surgeon, who may easily carry fatal infection—a veritable death sentence—beneath his finger-nail When a patient with a surgical disease takes cold in the wound, we now look for the signs of some septic contamination as the cause, and frequently find that absolute cleanliness will put an end to all the untoward symptoms.

Dr. Goodwin said that he had made some rather exhaustive studies in the department of bacteriology, and had had the common experience, that the ordinary means of illumination are quite insufficient for the purpose of detecting these small and refractory bodies.

He thought to buy an Abbé condenser, but found that it would cost here the sum of thirty dollars, which seemed too much to devote to one piece of accessory apparatus. Dr. Goodwin therefore obtained two ordinary plano convex lenses of about 1½ inches focal distance, and mounted them in metallic rings. These were now adjusted to each other so as to form almost a double convex lens, and are so adapted to the sub stage of the microscope as to act as a sub stage condenser. The surface of the upper lens is now ground at its centre so as to form a horizontal area of about one-half inch in diameter, the entire remaining ovoidal surface is rendered opaque by gently roughening it with a corundum strop, and the instrument is ready for use. With this means of illumination, Dr. Goodwin has been able to secure unusual power of penetration and definition, and has found that some forms of bacillary organisms are clothed with a pellucid envelope or capsule, which he has not seen mentioned by any other observer, in relation to these bodies.

Dr. W. N. Bullard read a paper on

CHRONIC TEA POISONING.

I desire to-night to draw attention to an affection which from its great frequency, the peculiar discomfort of its symptoms and its relative curability, is worthy of the careful consideration of the profession. At first sight it may seem surprising that so little has been either written or spoken in regard to this subject but I believe this to be principally due to two causes, firstly, the apparent ease with which any symptoms thus produced could be checked, by withdrawal of the existing agent, and secondly, to the indefiniteness and obscurity of these symptoms and the difficulty of proving their origin. During my study of this subject I have become more and more convinced that the latter difficulty is our greatest obstacle to a thorough knowledge of this affection, and that it is only to be overcome by the most careful investigation of each individual case and by the comparison of statistics drawn from a considerable number of such cases.

In the literature of this subject, which is curiously scanty and much of which has been written by the laity or from a non-professional point of view, I have been able to find only general statements, but few definite proved facts and *no* statistics.

In this paper we desire to confine our consideration to the cases of ordinary sub acute and chronic tea-poisoning, putting aside all acute cases, where large quantities of tea have been imbibed at a single sitting and all those of tea tasters or persons by profession exceptionally exposed to its toxic influence. In both these classes the symptoms are plain and well-known, and Morton's paper on tea-tasters leaves little more to be done in that direction except by those having special opportunities. The cases which I wish to consider are of the sort which present themselves daily to the general practitioner with symptoms sometimes obscure, and sometimes more or less pronounced.

The first fact which strikes the observer is the very gradual and insidious growth of the symptoms, which at first are frequently so slight and so indefinite as to be scarcely noticeable and only produce serious discomfort after a considerable period. This is one cause why their origin is not recognized by the patients themselves, and another reason for this may be found in the fact that the majority of them are of so general a character that they can readily be referred to some other source. Hence arises the difficulty in diagnosis, which so frequently occurs, and there are many cases in which it remains impossible to determine how far certain symptoms are the result of tea and how far they are due to other causes. As the cases become more severe the symptoms become more distinct and the diagnosis easier.

I will first describe a few cases of typical tea-poisoning and then proceed to the analysis of the symptoms.

Case 1. Boston Dispensary. Thomas G., about 55 years old, a horse-car washer. Complains of "rolling in the stomach" followed by flatus and tenesmus and has attacks of cold chills and weakness with a tendency to faint. He has staggered several times and come near fainting while at work, but has never fainted away. Has lost flesh lately. No palpitation, no cough. Drinks from one to three pints of tea per diem. He is emaciated and has a cachectic appearance. The heart and lungs are normal, so far as can be detected, except that the second sound is accentuated in the region of the pulmonary artery. Urine is normal in appearance, contains no albumen. Patient has lumbago and probably hæmorrhoids.

Case 2. Carney Hospital. Women, 40 years old. Diagnosis, "tea-dyspepsia." Patient is markedly nervous. She feels excited "as if afraid of somebody," especially when in a crowd. She used to have vertigo, but has never fallen. For two years she has been subject to distress in the epigastrium, palpitation, constipation, a dull heavy headache and dizziness, no cough. She drinks tea three times a day and also between meals.

Case 3. Woman 23 years old. Diagnosis, "tea-poisoning, anæmia." This patient applied at the Carney Hospital Out Patient Department on March 19, 1885, on account of bilateral headaches, frontal and occipital, accompanied by nausea and vomiting, which had occurred once a week for the preceding six months. She had been subject to these previously, but they were less severe and for about two years had been entirely absent. Her appetite was poor and she had a feeling of "weakness" in the epigastrium, but there was no distress after food, bowels regular. Had palpitation. Had never had rheumatism. Drank tea three times a day and also between meals. Under proper treatment she reported herself well on the 2d of April.

Case 4 Girl 13 years old Complains of pain in both sides, especially the left, nausea, but no vomiting, headache frontal and bilateral, palpitation and dyspnœa Bowels constipated The heart and lungs were normal, as far as could be detected There was some tenderness over the epigastrium Drank one to one and a half cups of tea three times a day This is a typical case of light tea-poisoning

Case 5 Woman 60 years old Dull frontal headache followed by "numbness" all over, which seems to be a sensation of weakness rather than a paræsthesia Attacks of dizziness, when she fears that she will fall Appetite poor No vomiting, but nausea with the headache Bowels regular Drinks pure black tea strong three times a day and occasionally between meals Distinct improvement in a week under treatment

Dr Henry I Bowditch said that this paper is a most useful and instructive contribution to what we knew only somewhat distinctly concerning the effects of tea, when its use has been persisted into such an extent as to produce true toxicological results Dr Bowditch has very decided views on the subjects of coffee and tobacco, but he has not so frequently observed the deleterious action of tea The Chinese in the tea-growing regions of the Flowery Kingdom take their tea in a manner very different from that to which we are accustomed The infusion is not so strong, being made of such a concentration that the bottom of the tea cup may be plainly seen through the infusion They use neither sugar or cream in the tea, and Dr Bowditch has found the flavor vastly improved by discarding these additions to tea as usually taken in this country All these substances are nervous stimuli, and all are capable of injurious influence upon the nervous system

The action is of the same nature as the stimulation from alcohol, but the effect is somewhat different, owing to the difference in the manner of taking the two substances, and probably too, owing to a difference in the particular mode of action of the substances Dr Bowditch related the case of a prominent politician, who was expected to appear and speak on a certain occasion, but who found himself quite unfitted mentally and physically to undertake the effort However, by the aid of a quantity of strong tea, he was able to keep his engagement, and to make a long and brilliant speech without betraying the signs of uneasiness or exhaustion

When the system is once saturated with either tea or tobacco, and the deleterious effects of these substances are once induced, there is nothing to do but to discard the articles at once and completely Nothing but "total abstinence" will be of any avail In Dr Bowditch's personal experience, he found that after once being saturated by coffee, a period of abstinence of fifteen years was not sufficient to remove the effect, but the moderate indulgence in coffee after this long interval was followed by the immediate reappearance of the original symptoms, on account of which the beverage was originally discarded Dr Bowditch has never heard a paper which so fully analyzed and so clearly explained the action of tea, as the work of the present author has done

Dr C P Putnam remarked that many physicians see patients in whom the influence of tea is plainly evident as a cause of depreciation of the general health Dr Putnam has seen many children, as well as adults, who were suffering from the effects of tea Frequently the diagnosis is a matter of great difficulty, and in obscure and puzzling cases it is not to be forgotten that the abuse of tea may be the sole cause One frequent symptom is that of ill defined distress, or at times actual pain, in the region of the heart or stomach, or in some other part of the abdomen, with constipation, which is proved to depend on the abuse of tea, and disappears upon the discontinuance of the harmful agent

The tea must be entirely withdrawn, as a small amount is sufficient to keep up the trouble

Dr Marcy stated that he had had two cases of tea-tasting One of these was a famous case The patient was well known in Boston as a celebrated tea-taster and confidential buyer for a well known tea house This patient died, and at the autopsy many gummous deposits were found distributed through the various organs of the body The patient had syphilis of Chinese origin Another man was in business in Boston He was habituated to tobacco, smoking fifteen cigars daily He was also a tea-taster, but never was affected by any symptoms referable to the tea Servants are fond of tea, and take it at all times of day, keeping the teapot on the fire all the time, and drinking from the dregs in the teapot The value of tea as a beverage is in its aroma, the dregs furnish a bitter, astringent and unpalatable infusion

Dr Bullard stated that it is very hard to form a correct estimate of the amount of tea which is taken This is particularly difficult in regard to servants, who are apt to underestimate the quantity they drink

Dr Weeks asked in how large a proportion of cases it is possible to persuade the victim to give up the use of tea

Dr Schofield said that the children of those who make large use of tea, and give it to their children, are often the subjects of obscure symptoms referable to the heart, which disappear on stopping the tea.

Dr E W Cushing stated that tea and coffee are much alike in one respect, from the fact that both contain a large amount of tannin, which is fully capable of causing a portions of the symptoms described, and may be the origin of a part of the trouble If tea were made in the manner employed in China the tannin would not be taken, and this element of disturbance would be removed Coffee may be prepared so as to deprive it of the tannin it contains, and it is then well borne, even by children It may be best made in this way Figs are taken as they are imported, and are baked so as to be of a brown color, and of taste and smell like caramel A portion of such prepared fig is boiled in the water, after boiling for a few minutes the coffee is added and prepared as usual Then an equal quantity of milk or cream is added and the coffee is served Coffee thus prepared consists of infusion of fig, some coffee and a good deal of milk

Dr Goodwin said that the tannin content of tea and coffee is so great that the tincture of chloride of iron cannot be given at the same time on account of the formation of ink in the stomach, and the consequent nausea

Dr Eastman remarked that the late Dr Jacob Bigelow was accustomed to speak of the tea and coffee as useful adjuncts to other forms of food and drink, but that they are only harmful when taken alone

In response to certain remarks in regard to the more injurious effect of tea after long infusion, Dr Bullard read the following quotation from Dr Roberts' Address on Therapeutics, delivered before the British Medical Association in 1885, as reported in the *British Medical Journal* of August 15th, 1885 "Some persons have supposed that by infusing tea for a very brief period—two or three minutes—the passage of tannin into the beverage could be avoided This, however, is a delusion Tannin is one of the most soluble substances known, it melts like sugar in hot water You can no more have tea without tannin than you can have wine without alcohol, and I found experimentally that tea infused for two minutes had almost exactly the same inhibitory effect on digestion as tea infused for fifteen or twenty minutes "

Dr Edes observed that one most frequent cause of dyspepsia is the fact that the diet is much deranged Too much drink and too little food is taken, and the patient gradually becomes anæmic, and the train of symptoms so often noticed in tea-poisoning gradually are developed In this way tea possesses one curious merit, as the patient can be sustained upon a more attenuated diet than when no tea is taken

Dr Farlow remarked that it is marvelous what a proportion of patients seen at the dispensary are totally ignorant of what is a proper condition of the bowels, and the little attention given to regularity of action in evacuation These patients are almost all tea topers, and are frequently insufficiently nourished They generally complain of a feeling of weight in the abdomen, and are also almost invariably nervous

Dr Blodgett said that Dr Cheever expected to have been present at this meeting, but was unavoidably detained This was the more to be regretted from the fact that Dr Cheever has had a large and interesting experience in the treatment of cases of disease arising from the inordinate use of tea The condition of these patients is not always the same, but presents a limited variation in the array of prominent symptoms One of the most frequently noticed conditions is a highly exalted state of the nervous system with increased reflex excitability, and a tremulous condition of the voluntary muscles, which justifies the name of "tea tremens," from the similarity of this symptom to the tremor belonging to cases of alcoholic poisoning This is most frequently noticed in servant girls, who partake frequently and exclusively of tea as a drink and do not obtain sufficient exercise in the air, and live principally on fine white bread, to the exclusion of other more wholesome and necessary articles of natural diet The result is that the system obtains only an insufficient nutrition, and the organs and functions of the body suffer a loss of organic or functional activity, or both A very important phenomenon in relation to the detrimental action of tea is its effect upon the teeth and other hard structures of the body This result is most noticeable in our Irish servant population, and particularly in the children born of parents who themselves emigrated to this country from Ireland The teeth of the parents are almost universally firm and durable in structure, and beautifully clear and white The teeth of the children, and especially those of the daughters, however, are found to be poorly formed, to be of brittle structure, and fall an easy prey to caries, and are lost at an early period This is undoubtedly due to the fact that many of these children are at service as house servants, and when following this occupation are addicted to the tea tippling and the fine bread above described The result is, that instead of the full and perfect denture of the parents who lived on plain and coarse food, without any of the abominations of our modern kitchens, these poor creatures obtain only a partial nutrition, the hard structures of the body being deprived of the necessary calcareous supply which resides in the the husk of grain, and is removed in the process of making fine flour, the teeth are insufficiently formed or inadequately maintained and consequently are early lost

Dr P C Knapp showed a series of

NORMAL ELECTRODES,

in which the size of the disk which is applied to the the surface in connection with the degree of intensity of current is measured by the resistance, constitutes a perfectly adjustable measure of the amount and intensity of the current employed, and is a necessary feature in the practical employment of electricity as a therapeutic agent

These electrodes are the sizes proposed by Erb[1] in 1882, and now accepted as the standard in regard to size, and with them a new size, recently proposed by Erb,[2] which merits a word of description In testing the galvanic excitability of nerve or muscle the appearance of contraction depends upon the absolute density of the current employed This absolute density varies of course directly with the intensity of the current which may be readily measured in milliampères on an absolute galvanometer, and it also varies inversely with the area of the electrode, just as the intensity of a stream of water varies inversely with the size of the tip of the pipe Hence we have the equation of D equals I divided by Q, where D equals absolute density, I equals intensity, and Q (querschnitt) equals area of electrode Having a ready measure for I in the milliampère, Erb has suggested the use of a "normal electrode" as a testing electrode, with an area of ten cm, either as a flake 3 2 cm square, or a round disc, like the one exhibited, with a diameter of 3 5—3 6 cm We may then say that KaSZ appears at 4 milliampères, normal electrode, or more simply, KaSZ appears at 4 10, or 4 milliampères, the numerator of the fraction denoting the number of milliampères, the denominator the area of the electrode

---

OBSTETRICAL SOCIETY OF PHILADELPHIA

Stated Meeting, Thursday, April 1, 1886

The President, B F Baer, M D, in the Chair

W H H Githens, Secretary

Dr E P Bernardy read a paper on

THE VALUE OF BINIODIDE OF MERCURY AS AN ANTISEPTIC IN OBSTETRICS

(See page 422)

Dr Chas Hermon Thomas had heard the statements of Dr Bernardy with interest, and surprise that cases of so much gravity could be controlled by such simple means as vaginal injections His practice and belief has been that such cases require the introduction of washes into the uterus, the washing of the vagina being utterly futile The doctor related an instance in which a four-para was allowed to die of septicæmia, no effort being made to wash out the uterus, although vaginal antiseptic injections were frequently employed in the case Six weeks have elapsed since the death of that patient, and in that time the same practitioner has lost three additional parturient patients

Dr Longaker spoke in support of Dr Bernardy's practice We have been led to expect a prompt fall of temperature from the use of intra uterine injections in septicæmia post-partum His own plan is to discontinue intra uterine injections after the first thorough washing, unless offensive discharges come from the uterus He has observed that after the repeated introduction of forceps into the uterus, the introduction of the hand or other means favoring the introduction of air, a peculiar traumatic metritis results, and to relieve this he has been in the habit of introducing into the uterus an iodoform pencil, containing about 1⅔ drachms of iodoform, this prevents future sepsis (see Lusk, last edition) Prompt lowering of the temperature and pulse are the result if this is used, after sepsis has occurred, and even when antiseptic uterine injections have failed The effect of one of these pencils will last through two or three days, when another may be needed

Dr Howard A Kelly drew attention to the fact that the biniodide of mercury is almost if not entirely insoluble in water, and that an alcoholic solution would hardly be admissable He also called attention to the frequent presence of the bichloride as an impurity He read the following letter from Dr Francis L Haynes

"In reference to the potassio mercuric-iodide, I may add a little to the facts I mentioned in our conversation The last case of puerperal septicæmia I have seen in my own practice occurred in Mrs F, confined December 18, 1885 It was due to the fact that my hands were contaminated with septic matter, and that I trusted entirely to hard scrubbing and to inunction with oil of turpentine to purify them (after Goodell) In this case the pulse was 138, and the temperature ran up to 105°, but she recovered in a few days under copious injections of hot water into the uterus (generally plain, but sometimes with a little carbolic acid added) These injections were given, and during the days on which this treatment was being used I attended several cases of labor, purifying myself with ten per cent solutions of carbolic acid These cases had no trouble, but I became ill, as I always do when I use much carbolic acid, and my hands became sore I now began to use the potassio mercuric iodide solution to purify my hands, and since then have had no trouble whatever, although I have attended cases of labor within a few hours after (1) washing out the uterus of a patient of Dr L's suffering from septicæmia (terminating fatally), (2) after amputating finger and metacarpal bone of a man suffering from gangrene of finger and suppurative cellulitis of the hand and wrist, (3) after digging out putrid placenta after miscarriage (several instances), (4) after performing autopsy in a case of suppurative peritonitis, and bathing my hands freely in the pus The solution may be used without apparent injury to purify blunt instruments, and it is certainly a great comfort to soak your speculum thoroughly in it after treating a case of gonorrhœa

How is the solution prepared? A four ounce bottle is marked with a diamond so as to indicate drachms, and filled with distilled water containing ʒj each of potassium iodide and mercuric iodide (The cost of this solution is less than ten cents) It is now a very easy matter to make a solution of any desired strength extemporaneously A tablespoonful to the pint = one part to 1000 is the strength I generally employ, but after autopsies I use 1 to 500

How do I prevent my hands from becoming eczematous when using the solution? Once or twice daily, after washing the hands and while they are still damp, about ʒss of glycerine is poured into the palm and thoroughly rubbed into the whole surface of the hands, which are then dried as usual This is very effectual,

Dr William Goodell has had no experience with biniodide of mercury, but has had with bichloride He is not sure that Dr Bernardy is at fault in confining his antiseptic injections principally to the vagina, for where does sepsis usually take place? Not in the uterus, but through wounds of the vagina In the Charlotte Hospital they have good results from the use of bichloride injections and iodoform When the Preston Retreat was new they had a good record, but afterwards the per centage of fatal cases became too large This fault was remedied by the use of bichloride of mercury as a vaginal injection, and the introduction of ʒj of iodoform The pads to catch the lochial discharges were replaced by absorbent cotton medicated with corrosive sublimate In the last 140 cases no rise of temperature has occurred during the puerperal period In these cases the antiseptic applications were all directed to the lower portion of the womb and the vagina Dr Bernardy is probably right A solution of 1 to 2000 is too strong and will produce soreness after operations He does not like to have the patient on her side during and after the removal of the afterbirth, as it favors the entrance of air into the vagina, as in Sims' position She should be on her back

Dr Harris inquired if Dr Bernardy did not use uterine injections after the removal of the dead fœtus The effect of a decomposing fœtus with unbroken membranes within the uterus has a remarkably prostrating effect upon both mind and body of mother

Dr **Githens** descibed a case of post-partum septicæmia in which an offensive leucorrhœa, which had existed before labor and which had been neglected, was the apparent cause In this case vaginal injections of potassi mercuric-iodide quickly relieved the undesirable symptoms

Dr **Thomas** thought vaginal injections would be quite sufficient as a prophylactic agent, but would it be considered sufficient if septic peritonitis were present? One thorough uterine wash first and then pencils to prepare for subsequent vaginal washes In Bellevue Hospital uterine injections are always used when required, washes failed to reduce the temperature

Dr **Bernardy** uses the first injection himself and thoroughly washes out the uterus and continues the injections until the fluid comes away perfectly clear The firm contraction of the uterus eliminates the liability of absorption there, and the principal abrasions and absorbing surfaces are undoubtedly vaginal The results at least have been satisfactory

The pellets exhibited are quite soluble, and are chemically pure, the biniodide has been tested for bichloride, and none is present The potassium iodide present merely aids in the solubility without affecting the chemical composition of the mercuric iodide

CHICAGO MEDICAL SOCIETY

Thirty fourth Annual Meeting, April 5, 1886

The President, C T Parkes, M D, in the Chair

The Treasurer, **Harold N Moyer**, M D, reported a balance of $226 17 in the treasury Dr **Edmund Andrews**, Chairman of the Committee on Library, reported a balance of $210 88, donations of 268 volumes, and purchases of about 1600 volumes during the year

The following were elected

OFFICERS FOR THE ENSUING YEAR

President—Dr Edmund J Doering
First Vice President—Dr Wm T Belfield
Second Vice-President—Dr J F Todd
Secretary—Dr Liston H Montgomery
Treasurer—Dr Harold N Moyer
Necrologist—Dr John Bartlett

STANDING COMMITTEES

Committee on Library—Dr Edmund Andrews (whose term had expired)

Committee on Judiciary—Dr Addison H Foster, Dr Wm E Quine, Dr Truman W Miller

Committee on Membership—Dr Gerhard C Paoli, Dr D A K Steele, Dr E F Ingals

Committee on Publication—Dr John A Robison, Dr E W Andrews, Dr R Tilley

The Society then elected the following

DELEGATES TO THE AMERICAN MEDICAL ASSOCIATION

Wm T Belfield,
Franklin H Martin,
D R Brower,
D W Graham,
D A K Steele,
Edwin Powell,
J H Plecker,
W W Allport,
N S Davis, Sr,
W W Jaggard,
H M Thomas,
Liston H Montgomery,
O T Schenick
N S Davis, Jr,
G C Paoli,
Charles T Parkes,
E M McAuliffe,
I N Danforth,
H M Starkey,
A R Reynolds,
F E Waxham,
F C Schaefer,
R H Babcock,
Augustus V Park,
E A Baldwin,
Charles W Purdy,
L T Potter,
Robert Tilley,
James Burry,
S C DeVeny,
W E Casselberry,
T W Miller,
F A Stanley

Those wishing to attend the next meeting of the Illinois State Medical Society may apply to the Secretary for delegates' certificates

FOREIGN CORRESPONDENCE

LETTER FROM PARIS

(FROM OUR OWN CORRESPONDENT)

The Summer Session of the Faculte de Medecine—The Lecturers—Intra parenchymatous Injections of Bichloride of Mercury in Tuberculosis—Congenital Fibrous Band of the Leg—The French Surgical Congress—Madame Ribard and Paul Bert

The summer session of the Paris Faculty of Medicine began on March 15th The following is a complete list of the lecturers and subjects for the session, in order that your readers may become acquainted with the names of the leading medical men of this city Professors Baillon, Medical Natural History, Béclard, Physiology, Guyon, Surgical Pathology, Brouardel, Medical Jurisprudence, Regnauld, Pharmacology, Bouchard, Pathology and General Therapeutics, Damaschino, Medical Pathology, Vulpian, Experimental and Comparative Pathology, Tarnier, Obstetrics, Proust, Hygiene, Hayem, Materia Medica and Therapeutics In addition to his theoretical lectures, Professor Brouardel delivers practical instruction at the Morgue on Forensic Medicine and Toxicology

Clinics —Professors Germain Sée, Medicine, at l'Hôtel Dieu, Hardy, Medicine, at La Charité, Potain, Medicine, at the Necker Hospital, Jaccoud, Medicine, at La Pitié, Richet, Surgery, at Hôtel Dieu, Verneuil, Surgery, at La Pitié, Trelat, Surgery, at La Charité, Le Fort, Surgery, at Necker Hospital

Specialties —Professors Ball, Mental Pathology and Diseases of the Encephalon, at the St Anne Asylum, Grancher, Diseases of Children, Fournier, Syphilitic and Cutaneous Affections, at the St Louis Hospital, Charcot, Diseases of the Nervous System, at the Salpétrière, Panas, Ophthalmology, at the Hôtel Dieu, Pajot, Clinical Obstetrics

Supplementary Lectures —These are delivered by Agrégés, who thus prepare themselves for the higher function of Professor The following are the names of those engaged for the session

Drs Joffroy, Medical Pathology, Humbert, Surgical Pathology, Hanriot, Medical Chemistry, Blanchard, Natural History, Gariel, Physics, Regnier, Physiology, Hanot, Morbid Anatomy, Pinard, Obstetrics

In addition to the above, practical instruction is given on the following subjects by

Drs Hanriot, Chemistry, Guébhard, Physics, Faguet, Natural History, Laborde, Physiology, Rémy, Histology, Farabeuf, Operative Surgery, Gombault, Morbid Anatomy

Thus it may be seen that the French medical students have great advantages over those of other countries, particularly as the above lectures are given gratuitously, and are open to all nations

The natural outcome of the parasitic doctrine of diseases is of course the tendency to cure them by remedies reputed to be anti parasitic, and these are generally applied either by the mouth or by external applications But Dr Gougenheim thinks that unless the parasites can be directly attacked these remedies can be of little or no avail He has therefore conceived the idea of treating pulmonary tuberculosis by intra-parenchymatous injections of the bichloride of mercury, and he lately read a paper on the subject before the Société Médicale des Hôpitaux de Paris The author performed the injections with a Pravaz's syringe, which he introduces on the left side below the clavicle, through the first intercostal space, and on the right side through the first two intercostal spaces In order to avoid all accidents it is necessary to make the injection at a distance from the sternum and the neighboring rib, in order not to injure the intercostal and mammary vessels and nerves, neither should it be made too near the clavicle, or the subclavian vein may be injured, the subcutaneous veins should be avoided The injection should be given slowly, and the liquid employed is a solution of the bichloride of mercury in the proportion of 1 in 2000, 1 in 1000, and 1 in 100, the fluid being previously heated to 37° (98 6° F)

This treatment was adopted with thirty-three patients, most of whom were in an advanced stage of phthisis In twenty-one instances improvement was quick and undeniable, as ascertained by auscultation Ten patients died, of these, seven presented local modifications of lesions, which were easily detected at the necropsies At the necropsies of patients who had been thus treated, Dr Gougenheim never observed any muscular, pleural, or pulmonary lesions, which could be attributed to these injections One patient had hæmoptysis, and the injections were discontinued, another left the hospital whilst under this treatment

Dr Reclus, at a recent meeting of the Paris Surgical Society, presented a female patient who was the subject of a rare lesion One of her legs was constricted by a congenital fibrous band Last year Dr Reclus removed two thirds of the band, and subsequently the remaining third The success resulting has been perfect It has been suggested that this case evidently belongs to the same class as those in which amputation is produced *in utero* by constricting bands

The French Surgical Congress will hold its second meeting at Paris from October 18 to October 21 The subjects contained in the programme are Nature, Pathogenesis and Treatment of Tetanus, Nephrotomy and Nephrectomy, Orthopædic Resections, Surgical Operations in Irreducible Dislocations Papers on other subjects cannot be read at the Congress unless the conclusions of the author are forwarded to the Secretary, Dr S Pozzi, 10 Place Vendome, Paris, between July 1 and July 13, 1886 Papers that are not read will not be printed in the transactions

Madame Ribard, M D , of Paris having been appointed physician to the family of M Paul Bert, the newly-appointed Governor-General of Tonquin, has left Paris for that Colony Madame Ribard is also entrusted with the organization of an Ophthalmic Hospital, as well as a vaccine establishment, in that country A B

DOMESTIC CORRESPONDENCE

LETTER FROM NEW YORK

(FROM OUR OWN CORRESPONDENT)

Is Disease of the Uterine Appendages as Frequent as has been represented—The Academy of Medicine, Changes in the Constitution

At the meeting of the Academy of Medicine held April 1, Dr Henry C Coe, Pathologist to the Woman's Hospital, read a very timely paper, entitled, *Is Disease of the Uterine Appendages as Frequent as it has been Represented?* which it is hoped will have some effect, at least, in putting a check upon the altogether reckless resort to Tait's operation which has of late been of such frequent occurrence in this country Having remarked that there was much yet to be learned in regard to the pathology of these organs, he said very truly that agnosticism in regard to ovarian and tubal disease met with very little encouragement at the present day, and that this was due to a large extent to the surgeon

In considering the condition and appearance of the ovary in any given case, he said, it must not be forgotten that during the entire sexual life of the female constant changes are going on in these organs Hence it was often very difficult to say just where the normal ends and the pathological begins Nothing was at present more common than to remove ovaries because they were "cystic," on the ground that because of this condition they were functionally useless Yet he had seen cysts as large as a marble which could not be called pathological, since they contained perfectly healthy ova which were certainly capable of being impregnated Taking up the pathological conditions of the ovary as viewed by the laparotomist, Dr Coe said that many of the variations of the organ in size and shape which were commonly regarded as pathological by him were found in ovaries which were to be looked upon as in fact entirely normal, at least as far as function was concerned Congestion and moderate enlargement did not necessarily imply chronic ovaritis and indicate oophorectomy, since, when the other pelvic organs were for any reason in a state of hyperæmia, the ovaries were naturally found hyperæmic also

In the same way, a decided diminution in size might not be pathological, but merely an indication of senile atrophy Again, certain conditions which are regarded by the laparotomist as pathological, such as thickening of the external covering of the organ, might not be so in reality, since such thickening was not at all abnormal in senile atrophy, or after very frequent ovulation, when localized thickening is very common, even when senile atrophy does not exist But, although there might be exterior thickening, it was no indication that there was cirrhosis of the internal stroma of the organ which interfered with its functions

Passing on to consider the subject from a microscopical point of view, he said that in order that the pathologist might give an intelligent opinion concerning any removed ovary presented to him for examination, he must be familiar with the normal histology of the organ, and, on account of the constant changes going on in the ovaries, previously referred to, this was a matter which involved no little difficulty The pathological appearances of well marked disease were readily recognizable, but the lesser ones were undoubtedly very hard to differentiate Again, because one portion of the organ was affected, it was no reason why the whole ovary should be implicated in the pathological process, and, acting on this principle, Schroder had lately been operating in such a way as to remove the diseased portions, and allow the rest to remain The number of cases thus far recorded, however, was too small to base any positive conclusions upon as to the practical utility of this method, but it was, at all events, a step in the right direction

In speaking of tubal disease he said that there could be no doubt that Tait's operation had of late been greatly abused No reasonable objection could be urged against the removal of Fallopian tubes which were filled with pus, but this was not the case with a large number of the tubes which are taken out Tait said that in chronic disease of the ovaries the tubes were always affected, but Dr Coe denied this, as the result of his personal pathological investigations Some of the so called diseases of the tubes were not recognizable by the pathologist at all There was no doubt about pyo salpinx or hydro-salpinx, when these conditions were present, but as to so called "catarrhal salpingitis," commencing pyo salpinx, and other presumed pathological conditions which constantly pass unchallenged in learned societies, there was very good reason for doubt In cases where the diagnosis of catarrhal salpingitis had been made, and the tubes and ovaries removed in consequence of the condition, Dr Coe had found on subsequent examination simply moderate hyperæmia, with a thin coating of mucus, which might exist in a perfectly normal Fallopian tube, there being no evidence whatever of any inflammation As long as the lumen was free, and the lining mucous membrane capable of performing its function, the tube was not abnormal, notwithstanding the fact that there might be slight adhesions of the fimbriated extremity

From his examinations he could say that pyo salpinx exists in about one-fifth of the cases where Tait's operation is performed Hydro salpinx is considerably less common, and hæmo salpinx extremely rare If there was no pus discernible, there was certainly no pyo salpinx, just as there could be no abscess anywhere without pus The pain that was so often attributed to disease of the tubes Dr Coe believed to be generally due to localized peritonitis, and sometimes to neuralgia pure and simple The one criticism that he had to make on American laparotomists, he said, was that they do not follow up their cases for a sufficiently long time As a rule, they were reported very shortly after the operation, when the results often seem all that could be desired, but if the histories could be given at the end of from six months to two years, it would not infrequently be found that no permanent benefit whatever had resulted from the procedure He had met with many women under these circumstances who still suffered in the same way as before the operation

The deductions drawn by Dr Coe were somewhat as follows

1 Ovarian disease is not as common as is now generally supposed This impression is derived from the surgeon, and not from the pathologist

2 Because the ovary is partially diseased, it does not follow that the whole organ is involved in the pathological process

3 "Cystic" and "cystic degeneration" are mischievous terms, which have been productive of much evil by leading to false conclusions and unnecessary ovariotomies in consequence

4 Actual disease of the tubes is far less frequent than many surgeons would have us believe

5 Localized peritonitis will account for much of the trouble attributed to disease of the uterine appendages

While some of the gynecologists who took part in the discussion of the paper were disposed to take issue with its author in regard to the frequency of disease of the uterine appendages, it was noticeable that without an exception they all condemned the frequent removal of these organs Even Dr W Gill Wylie, whose name is more closely identified with Tait's operation than almost any other New York laparotomist, was careful to put himself on record on the conservative side by stating that at the present time he seldom or never resorted to this procedure except in the case of pyo salpinx

Dr Lusk, whose views were more entirely in accord with those of the essayist of the evening than any of the other speakers, remarked that in his paper Dr Coe had covered nearly all the ground which he had himself been accustomed to take in the tirades against the abuse of Tait's operation with which many of his gynecological friends were now familiar He was by no means an enemy of the operation, he said, but thought it did great good in its place More than once, however, he had stood by and seen tubes removed which were described by various pathological designations, but which seemed to him to be entirely normal In the same way, he had seen ovaries taken out, of which it was said that they were in a state of commencing cystic degeneration, but which appeared to him typical examples of physiological ovaries, precisely like those he had formerly been accustomed to exhibit to his classes as such when he used to teach that branch of physiology He then took great interest, he said, in pointing out the changes which are constantly going on in these organs, and these so called cystic ovaries, which had been removed for imaginary disease, were simply ovaries which were undergoing these same physiological changes Since surgeons had come to be able to remove the ovaries and tubes with comparatively little risk to the patient, the operation was performed entirely too frequently Tait's advice was to cut open the abdomen and examine the condition of the uterine appendages, when, if they were found all right, they were to be returned to their places in the pelvic cavity But he himself had yet to meet with the surgeon who after getting thus far in the operation, did not take out the organs altogether, whatever their condition might be

Dr Lusk believed that there were very few cases in which the condition of pyo salpinx could not be diagnosticated by proper manipulation with the fingers of one hand in the vagina, and that the great mistake of the present day among gynecologists was the too frequent opening of the abdomen Unless the enlarged tube could be felt, in the manner described, outside the body, the operation ought not to be performed, and he said that if this rule were generally observed, there would not be so many tubes removed In the course of time he thought it probable that even in this class of cases Tait's operation might be avoided by the use of some such instrument as that devised by Dr Mundé, which consists of a syringe with a hypodermic needle attached

In regard to this last point of Dr Lusk Dr Wylie said that he did not think that aspiration would cure any case of pyo salpinx, because the pus would be sure to return after it had been evacuated Another objection to it was that there was a possibility of causing fatal injury with the instrument, by wounding the uterus In the course of his remarks Dr Wylie expressed his conviction that in the great majority of cases localized peritonitis was associated with disease of the ovaries and tubes, an opinion which was also coincided with by Drs Polk, Munde and Noegerrath

In closing the discussion Dr Coe stated that his anatomical studies had led him to look with some doubt upon a diagnosis resting on clinical observation alone Fearing that the position which these investigations had obliged him to take in regard to the comparative infrequency of disease of the uterine appendages might perhaps be thought not altogether well supported, he had written to obtain the opinion of Dr Wm H Welch, now of the Johns Hopkins University, of Baltimore, who was acknowledged to be one of the most distinguished microscopists in the country, and who had had a very large experience in this special field Dr Welch had replied that he believed Dr Coe's position to be well taken He said that he saw very few cases of pyo salpinx in his examinations, and that he was continually receiving ovaries and tubes, removed by laparotomy, which were, as far as he could make out, entirely free from disease He furthermore expressed the opinion that it was a mistake to suppose that the so called "cystic" ovaries would degenerate into cystoma

It is probably not known at all out of New York, and perhaps to a very limited extent among the profession even here, what radical changes have been made during the past winter in the constitution and by laws of the Academy of Medicine These changes, however, constitute them, in many essential features, an entirely different instrument from the old constitution and by-laws In comparing the old and the new constitution, the first change that strikes one is in regard to the objects of the Academy In the old, these are stated to be (1) The cultivation of the science of medicine (2) The advancement of the character and honor of the profession (3) The elevation of the standard of medical education (4) The promotion of the public health In the new, the single object is announced to be "the promotion of the science and art of medicine" While many of the changes are decided improvements, as regards the details of the work of the Academy and the simplicity and accuracy of the wording of the various sections, the most striking and extraordinary one is in regard to the matter of ethics In the new constitution and by-laws there is absolutely no reference in any manner whatever to this subject In the old by-laws, Section 5 of No XIV reads as follows "All questions of ethics in other respects shall, as far as applicable, be adjudged in accordance with the Code of Ethics promulgated by the American Medical Association and adopted by the Academy" In the new instrument not only is the New Code not substituted for the National one, but it out-Herods Herod by cutting completely loose from all codes

Practically the only reference to the matter of discipline now found is in the eighth article of the constitution, in which it is provided that the Academy may, by a three-fourths vote of the resident Fellows (the printed call for the meeting having contained a notice of the motion to suspend or expel), suspend or expel a Fellow 'for violation of its regulations" The only other reference to discipline in the constitution is in Article VII, where it is stated that the certificate of fellowship may be revoked for cause, but as there is no provision whatever for the manner in which this revocation is to be accomplished, it really amounts to nothing The only reference of the kind in the by-laws is in the eleventh section of No X, which reads as follows "It (the Council) shall, on a written statement signed by a complainant, and duly forwarded through the Recording Secretary, take cognizance of any complaint against a Fellow The Council may, after investigation, dismiss a complaint or transmit its finding thereon to the Academy for further action" From this it will be seen that the matter of disciplining is therefore wholly comprised in Article VIII of the constitution, which, as just mentioned, prescribes that he may be suspended or expelled for violation of the Academy's regulations As there is nothing whatever in these "regulations" of the faintest ethical import, it is evident that a Fellow can be suspended or expelled solely for a breach of certain routine rules He may be a debauchee, or sot, a blackleg or a thief, but so long as he acts in accordance with these "regulations," the Academy cannot touch him, and if it attempted to do so, the defense that he had not violated the regulations would hold good in any court of law There is not even the saving clause of "conduct unbecoming a gentleman" anywhere to be found

Furthermore, it is not necessary, so far as any statutory provisions are concerned, that in order to belong to the Academy a person should be a *regular* graduate in medicine So far as regards any restriction in the constitution or by-laws, a homœopath, eclectic, "physio medical," "herb doctor," or any kind of a charlatan whatever, is entitled to become a Fellow if only he is the possessor of a diploma or license, and has resided in New York or its vicinity for three years There is absolutely nothing said about what sort of a college or other body the candidate must have derived his diploma or license from, it is simply required that he "must have been a graduate or licentiate in medicine" It is noticeable that the committee on education, as well as that on ethics, has been entirely abolished

Hitherto the Academy of Medicine, although many of its Fellows individually repudiated the National Code, has been entitled, as a body, to representation in the American Medical Association by reason of its technical adherence to the Code, but, of course, now that it has repudiated the latter in its corporate capacity, it has placed itself in the same anomalous position as the Medical Society of the State of New York P B P

LAPAROTOMY FOR PELVIC ABSCESS

To the Editor of the Journal

Dear Sir —I entirely agree with Dr Christian Fenger in his remarks on Dr Jackson's paper, in a recent meeting of the Chicago Gynecological Society, when he says "The operation performed in Dr Jackson's case I should not call a laparotomy at all, but simply an oncotomy An abscess was opened, and the operation does not differ materially from the opening of a deep-seated abscess in any other region of the body, *e g*, in an extremity"

In the cases reported done in this country there was one performed by me in June, 1884 I think it was the first successful case of laparotomy for pelvic abscess done in this country It will be found in the *Medical News*, for 1884 In this case the sac of the abscess was stitched to the abdominal wound, and then opened and drained The woman is still living and in excellent health I think this case was reported by Dr Stone, my assistant, and is probably referred to in Dr Fenger's list, given in his remarks

Very respectfully, R S Sutton, M D

419 Penn Ave, Pittsburgh.

STATE MEDICINE

REGULATION OF MEDICAL PRACTICE IN IOWA

The following Bill for an act to regulate the practice of medicine and surgery in the State of Iowa has been recently passed

Be it enacted by the General Assembly of the State of Iowa

Section 1 That every person practicing medicine, surgery or obstetrics, in any of their departments, within this State, shall possess the qualifications required by this act If a graduate in medicine such person shall present his or her diploma to the State Board of Examiners, for verification as to its genuineness If the diploma is found genuine and is issued by a medical school legally organized and in good standing, of which the State Board of examiners shall determine, and if the person presenting and claiming such diploma be the person to whom the same was originally granted, then the State Board of Examiners shall issue its certificate to that effect signed by not less than five physicians thereof, representing one or more physicians of the schools on the board, and such certificate shall be conclusive as to the right of the lawful holder to practise medicine, surgery and obstetrics within this State If not a graduate the person practising medicine or surgery within this State, unless he or she shall have been in continuous practice in this State for a period of not less than five years, of which he or she shall present to the State Board of Examiners satisfactory evidence in the form of affidavits, shall appear before said State Board of Examiners and submit to such examination as said board may require All examinations shall be conducted in writing, and all examination papers, together with the reports and action of the examiners thereon, shall be preserved as the records of the board for a period of five years, during which time they shall remain open for inspection at the office of the said State Board of Examiners Such examinations shall be in anatomy, physiology, general chemistry, pathology, therapeutics, principles and practice of medicine, surgery and obstetrics *Provided*, that each applicant upon receiving from the secretary of the board an order for an examination shall receive also a confidential number which he or she shall place upon his or her examination papers so that when said papers are passed upon by the examiners, the latter shall not know by what applicant said papers have been prepared That upon each day of examination all candidates be given the same set or sets of questions It is further provided that the examination papers shall be marked upon the scale of one hundred (100) and that in order to secure a license, it shall be necessary for the applicant to attain such average as shall hereafter be determined by the State Board of Examiners And if such examination be satisfactory to at least five physicians of said board, representing the different schools of medicine on the board, the board shall issue a certificate which shall entitle the lawful holder thereof to all the rights and privileges herein provided, and the physicians and the secretary of the State Board of health shall constitute and be deemed a Board of Examiners for the purpose of this act

SEC 2 The State Board of Examiners shall procure a seal within sixty days after the passage of this act, and through the secretary of said board shall receive applications for certificates and examinations The president, or any member of the board, shall have the authority to administer oaths and take testimony in all matters relating to their duties as examiners aforesaid The board shall provide three forms of certificates One for persons in possession of genuine diplomas, one for candidates examined by the board, and one for persons who have practised medicine or surgery in any of its departments for five years as provided in this act Said certificates shall be signed by not less than five physicians of the board, and this number may act as examining board in the absence of the full board, provided that one or more members of the different schools of medicine represented in the State Board of Health shall also be represented in the Board of Examiners The Board of Examiners shall hold meetings at such places as will best accommodate applicants residing in different portions of the State, and at such times as they shall deem best and due notice of the time and place of such meetings shall be published

SEC 3 The board shall examine all diplomas submitted to them for such purpose to determine their genuineness and the rightful ownership of the person presenting the same The affidavit of the applicant and holder of any diploma that he or she is the person therein named, and is the lawful possessor thereof, shall be necessary to verify the same with such other testimony as the board may require Diplomas and accompanying affidavits may be presented in person or by proxy If the diploma shall be found genuine, and in possession of the person to whom it was issued, the State Board of Examiners shall, upon the payment of a fee of two dollars, to the secretary of the board, issue a certificate to the holder of such diploma, and no further fee or sum shall be demanded or collected from said applicant by said board for such certificate If the diploma shall be found to be fraudulent, or not lawfully in the possession of the holder or owner thereof, the person presenting such diploma or holding or claiming possession thereof, shall be deemed guilty of a misdemeanor, and on conviction thereof, before any court of competent jurisdiction, be fined not less than twenty dollars nor more than one hundred dollars

SEC 4. Every person holding a certificate issued by the State Board of Examiners, shall, within sixty days after the date of such certificate, have the same recorded in the office of the county recorder in the county wherein he resides, and should he remove from one county to another to practise medicine, surgery or obstetrics, his certificate must be recorded in the county to which he removes The county recorder shall indorse upon the certificate the date of record, and he shall be entitled to charge and receive a fee of fifty cents for his services, to be paid by the applicant

SEC 5 The county recorder shall record in a book provided for that purpose, a complete list of the certificates presented for record, and the date of their issue by the State Board of Examiners If the certificate is issued by reason of a diploma, the name of the medical college conferring the same, and the date when conferred shall be recorded, and when such certificate shall have been granted upon the examination of the board, or because of seven years' practice in the State, such facts shall be recorded Said record shall be open for inspection during business hours

SEC 6 Candidates for examination shall pay in advance to the Secretary of the State Board of Examiners, a fee of ten dollars, which fee, together with the fees received for certificates, shall defray the entire expense of the aforesaid Board of Examiners, and the balance shall be turned over to the State Treasurer for the benefit of the school fund, except such an amount as will pay each member of the Board ten dollars ($10) per day during the time he is in actual attendance upon the session of the said Board for the purpose of performing the duties required of him under this act, and as will pay the Secretary of Board such a salary as they may allow, not to exceed five dollars per day during the time he is actually engaged in performing the work of the Board under this act, and each member of the Board of Examiners shall also receive a sufficient amount to defray his actual and necessary expenses while in the discharge of the duties herein provided Any one failing to pass the required examination, shall be entitled to a second examination within twelve months without fee Provided that any applicant for examination by notice in writing to the Secretary shall be entitled to an examination within three months from the time of said notice, and a failure to give such opportunity, shall entitle such applicant to practice without the certificate required by this act, until the next regular meeting of said Board

SEC 7 The State Board of Examiners may refuse to grant a certificate to any person who has been convicted of a felony committed in the practice of his profession, or in connection therewith, may revoke certificates for like cause, or for palpable evidence of incompetency, and such refusal or revocation shall prohibit such person from practicing medicine, surgery and obstetrics, *provided*, such refusal or revocation of a certificate can only be made with the affirmative vote of at least five physicians of the State Board of Examiners, in which number shall be included one or more members of the different schools of medicine represented in said Board, and *provided, further*, that the standing of a legally chartered medical college from which such a diploma may be presented, shall not be questioned except by a like vote

SEC 8 Any person shall be deemed as practising medicine, surgery or obstetrics, or to be a physician within the meaning of this act, who shall publicly profess to be a physician, surgeon or obstetrician and assume the duties, or who shall make a practice of prescribing or of prescribing and furnishing medicine for the sick, or who shall publicly profess to cure or heal, by any means whatsoever, but nothing in this act shall be construed to prohibit students of medicine, surgery or obstetrics from prescribing under the supervision of preceptors, or gratuitous service in case of emergency, nor shall this act extend to prohibit women who are now engaged in the practice of midwifery, nor to prevent the advertising, selling or prescribing natural mineral waters flowing from wells or springs, nor shall this act apply to surgeons of the United States army and navy, and marine hospital service, nor to physicians as herein defined who have been in continuous practice in this State for seven years, three years of which time shall have been in one locality, *provided*, such physician shall furnish the State Board of Examiners satisfactory evidence of such continuous practice, and shall procure the proper certificate as provided in this act, and for which certificate such physician shall pay to the Secretary of the State Board of Examiners a fee of two dollars, and the Board of Examiners shall grant a certificate to such applicant, nor shall this apply to registered pharmacists when filling prescriptions, nor shall it be construed to interfere with the sale of patent or proprietary medicines in the regular course of trade

Sec 9 Any person who shall practise medicine or surgery within this State, without having complied with the provisions of this act, and who is not embraced in any of the exceptions, or after being prohibited from so doing, as provided in section 7 of this act, shall be deemed guilty of a misdemeanor, and shall, on conviction thereof, be punished by a fine of not less than fifty nor more than one hundred dollars, or by imprisonment in the county jail not less than ten days nor more than thirty days

Sec 10 Any person who shall file, or attempt to file, with the State Board of Examiners, as his or her own, the diploma of another person, or who shall file or attempt to file with the county recorder the certificate of another person as his or her own, or who shall file or attempt to file a diploma or certificate with the true name erased therefrom and the claimant's name inserted, or who shall file or attempt to file any forged affidavit of identification, shall be deemed guilty of the crime of forgery

Sec 11 The penalties, as provided in this act, for violations thereof, shall not be enforced prior to the first day of January, A D 1887

Sec 12 All acts or parts of acts in conflict with this act, are hereby repealed

---

ASSOCIATION ITEMS.

AMERICAN MEDICAL ASSOCIATION

The Thirty-seventh Annual Session will be held in St Louis, Mo, on Tuesday, Wednesday, Thursday and Friday, May 4, 5, 6 and 7, commencing on Tuesday at 11 A M

The delegates shall receive their appointment from permanently organized State Medical Societies and such County and District Medical Societies *as are recognized by representation in their respective State Societies*, and from the Medical Department of the Army and Navy, and the Marine Hospital Service of the United States

Each State, County, and District Medical Society entitled to representation shall have the privilege of sending to the Association one delegate for every ten of its regular resident members, and one for every additional fraction of more than half that number *Provided*, however, that the number of delegates for any particular State, territory, county, city or town shall not exceed the ratio of one in ten of the resident physicians who may have signed the Code of Ethics of the Association

Secretaries of Medical Societies, as above designated, are earnestly requested to forward, *at once*, lists of their delegates

Also, that the Permanent Secretary may be enabled to erase from the roll the names of those who have forfeited their membership, the Secretaries *are, by special resolution*, requested to send to him, annually, a corrected list of the membership of their respective Societies

SECTIONS

"The Chairman of the several Sections shall prepare and read, in the general sessions of the Association, papers on the advances and discoveries of the past year in the branches of science included in their respective Sections "—*By-Laws*, Art 11, Sec 4

Practice of Medicine, Materia, Medica and Physiology—Dr J T Whittaker, Cincinnati, Ohio, *Chairman*, Dr B L Coleman, Lexington, Ky, *Secretary*

Obstetrics and Diseases of Women and Children—Dr S C Gordon, Portland, Me, *Chairman*, Dr J F Y Paine, Galveston, Texas *Secretary*

Surgery and Anatomy—Dr Nicholas Senn, Milwaukee, Wis, *Chairman*, Dr H H Mudd, St Louis, Mo, *Secretary*

State Medicine—Dr John H Rauch, Springfield, Ill, *Chairman*, Dr F E Daniel, Austin, Texas, *Sec'y*

Ophthalmology, Otology, Laryngology—Dr Eugene Smith, Detroit, Mich, *Chairman*, Dr J F Fulton, St Paul, Minn, *Secretary*

Diseases of Children—Dr W D Haggard, Nashville, Tenn, *Chairman*, Dr W B Lawrence, Batesville, Ark, *Secretary*

Oral and Dental Surgery—Dr John S Marshall, Chicago, Ill, *Chairman*, Dr A E Baldwin, Chicago, Ill, *Secretary*

A member desiring to read a paper before a Section should forward the paper, or its *title* and *length* (not to exceed twenty minutes in reading), to the Chairman of the Committee of Arrangements, at least one month before the meeting—*By-Laws*

Committee of Arrangements—Dr Le Grand Atwood, St Louis, Missouri, *Chairman*

AMENDMENTS TO BY-LAWS

By Dr Foster Pratt, Mich—Each Section shall nominate its Chairman and Secretary—all other nominations to be made, as now, by the nominating Committee

By Dr I N Quimby, N J—Create a new Section, to be known as the Section on Medical Jurisprudence

Wm B Atkinson, M D,
Permanent Secretary
1400 Pine St, S W cor Broad, Philadelphia

Round Trip Tickets at reduced rates will be issued to delegates attending the next meeting of the American Medical Association, on the 4th of May next, at St Louis, Mo , by the following agents of the Chesapeake & Ohio Railroad H W Fuller, Gen'l Pass Agent, Richmond, Va , Frank Trigg, Pass Agent, 513 Pennsylvania Ave , Washington, D C S R Seal, Ticket Agent, 339 Broadway, N Y The trip on the ocean from New York via the Old Dominion line of steamers to Old Point Comfort, or Richmond, Va , is perfectly delightful at this season of the year, and from those points and Washington City over the C & O , through the mountains of Virginia via the celebrated White Sulphur Springs, West Virginia and Louisville to St Louis, Mo , the scenery is grand and beautiful beyond description Delegates from all points on the Missouri Railroad, including Kansas City and St Joseph, Mo , Leavenworth and Atchison, Kan , and Omaha, Neb , will have until May 30 before returning

Other weekly medical journals will please copy

R M Jordan, M D ,
Chairman Transportation Committee
St Louis Mo

Railway Facilities to the Association Meeting —The regular through trains of the Illinois Central Railroad from Chicago to St Louis will afford excellent accommodations for delegates who wish to attend the meeting of the American Medical Association at St Louis the first week in May The night express, with Pullman sleeping cars, leaves Chicago at 8 30 p m , and arrives in St Louis at 7 a m The rates are $7 50 round-trip

The rates on the Baltimore and Ohio Railway for those coming from the East and South east are full fare coming and one third fare returning

The Illinois Central, Chicago and Alton, and the Wabash Railways have agreed to fix the rates from Chicago to the meeting of the Association, for members, at $7 50 *round trip*

The rate by the Pennsylvania Railroad, from Philadelphia to St Louis and return, will be $30 35 By the Baltimore and Ohio, in consequence of their low Western rates, it will be $23 75, with the privilege of stop over at Washington or Baltimore if desired

MISCELLANEOUS

Notice of Removal — Dr T Gaillard Thomas has removed from 294 5th avenue, New York, to 600 Madison avenue, between 57th and 58th streets

The Local Committee of Arrangements and the Death of Dr Flint — *Whereas,* The members of the Local Committee of Arrangements have heard with sorrow of the sudden death of Professor Austin Flint, M D , LL D , whose eminent services to medical science, and whose life work in practical medicine had endeared him to the medical profession, and whose private and personal character was such as to insure him the admiration and respect of the profession in this country and abroad, therefore, be it

Resolved, That this Committee thus publicly express their deep regret at his death, and tender to the family of the deceased their most profound sympathy

J B, Hamilton, M D ,
A Y P Garnett, M D , } *Committee*
D R Hagner, M D ,
Washington, April 5, 1886

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY FROM MARCH 27 1886 TO APRIL 9 1886

Major Henry McElderry, Surgeon, relieved from further duty in connection with the New Orleans Exposition, and ordered, on the expiration of his present leave of absence, for duty in Dept East (S O 71, A G O , March 26, 1886)

Asst Surgeon Leonard Y Loring, granted leave of absence for one month, provided that during his absence he furnishes the necessary medical attendance at San Diego Bks , Cal (S O 19, Dept Cal , March 24, 1886)

Asst Surgeon Jno Van S Hoff, granted one month's leave of absence (S O 29, Dept Mo , March 29, 1886)

Asst Surgeon J M Banister, granted leave of absence for one month, to commence on or about April 2, 1886 (S O 63, Dept East, March 26, 1886

Asst Surgeon Aaron H Appel, granted leave of absence for one month (S O 66 Dept East, March 30, 1886)

Major Albert Hartsuff Surgeon, granted leave of absence for fifteen days (S O 71, Dept East, April 7, 1886)

Major Henry McElderry, Surgeon U S Army, ordered for duty as Post Surgeon, Ft Wayne, Mich (S O 69, Dept East, April 2, 1886)

Capt James C Merrill, Asst Surgeon, granted leave of absence for three months (S O 81, A G O , April 7, 1886)

Capt Victor Biart, Asst Surgeon, sick leave of absence still further extended one year on account of sickness (S O 79, A G O , April 5, 1886)

Asst Surgeon Richard W Johnson, relieved from duty at Ft Buford, D T , and ordered for temporary duty at Ft Snelling, Minn (S O 28, Dept, Dak , March 29, 1886)

Asst Surgeon R L Robertson, on expiration of his present leave of absence, will be relieved from duty in Dept Texas, and will report in person to commanding general Dept Dak for assignment to duty (S O 78, Dept Dak , April 3 1886)

Capt Jno V Lauderdale, Asst Surgeon, from Dept Dakota to Dept Texas

Capt Geo W Adair, Asst Surgeon, from Dept Dakota to Dept East

Capt Jas A Finlev, Asst Surgeon, from Dept Texas to Dept Dakota

Capt H S Kilbourne, Asst Surgeon, from Dept Dakota to Dept Columbia

Capt E F Gardner, Asst Surgeon, from Dept Columbia to Dept East

Capt Wm W Gray, Asst Surgeon, from Dept East to Dept Dakota

Capt J M Banister, Asst Surgeon, from Dept East (upon the expiration of his present leave of absence) to Dept Columbia

First Lieut E C Carter, Asst Surgeon, from Dept Arizona to Columbus Bks , Ohio

First Lieut R W Johnson, Asst Surgeon, from Dept Dakota to Dept East

First Lieut Geo F Wilson, Asst Surgeon, from Dept Columbia to Dept Dakota (S O 79, A G O , April 5, 1886)

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U S NAVY DURING THE TWO WEEKS ENDING APRIL 10 1886

Atlee, L W , Asst Surgeon *ordered to duty on U S R S "Vermont"*

Drake, N H , P A Surgeon, detached from duty at Naval Hospital, Philadelphia, and ordered to duty at Naval Hospital, Brooklyn, N Y

Fitts, H B , P A Surgeon, detached from duty at Naval Hospital, Brooklyn, N Y , and ordered to duty at Naval Hospital, Philadelphia

Anderson Frank, P A Surgeon, detached from Naval Laboratory New York, and granted six months' leave from May 1, 1886, with the privilege of going abroad

THE TREATMENT OF COMPOUND FRACTURES BY WIRING AND DRAINAGE[1]

BY W P. VERITY, M D ,

OF CHICAGO, ILL

SURGEON TO THE COOK COUNTY HOSPITAL

Bilroth, in an edition of his "Surgical Pathology," written before antisepticism had begun to struggle for an existence, says " The treatment of complicated fractures is one of the most difficult problems in surgery We never cease learning on this point" In this view of the case may be found my apology for the introduction of a seemingly exhausted topic for discussion

In the procedure I am about to describe, there is no single *detail* which is strictly original, but the procedure as a whole deserves the attention of the profession When a comminuted fracture comes under my observation, the affected part and its surroundings are carefully cleansed and shaven Soft parts so ragged and contused, and so situated as to produce separation of the fragments and to act as foreign bodies, are removed, as likewise all foreign bodies, the external wound being enlarged, if necessary, for this purpose If the part affected be a lower extremity, this is flexed at an obtuse angle The fragments are then approximated in the most normal position possible For this purpose projecting sharp points, if denuded and acting as irritants, may be removed, as in Case 4, but an effort should be made to retain all such fragments as means of support, as in Case 2 When the best possible approximation is secured, the fragments are wired or nailed together, silver wire (when of good quality) is preferable, but iron wire is the most attainable and can be readily disinfected by means of heat and rendered properly flexible Drainage is secured by means of large tubes from the most dependent point The whole extremity is then covered with an extensive thick antiseptic dressing, and incased in a plaster cast, removable at each dressing The present procedure has certain very demonstrable advantages in cases which otherwise could not be treated antiseptically in a thorough manner

In illustration of these advantages the following cases may be cited *First* All points of bone and injured tissue fragments, *likely* to act as irritants, are removed, except where bone point is needed for mechanical support This is well illustrated by the following case

Case 1 —C W S , white, aged 39, a painter, had a recurrent attack of erysipelas, but no venereal disease, he fell from a scaffold, sustaining a compound comminuted fracture of the tibia and fibula

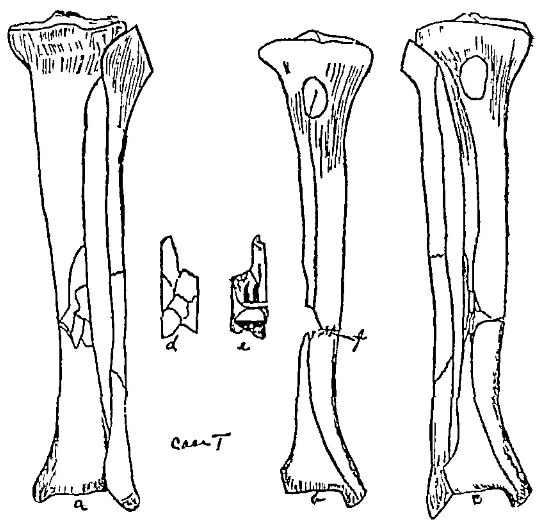

FIGURE 1 —*A* posterior view *B*, anterior view *C* lateral view *D* and *E*, fragments *F*, wire

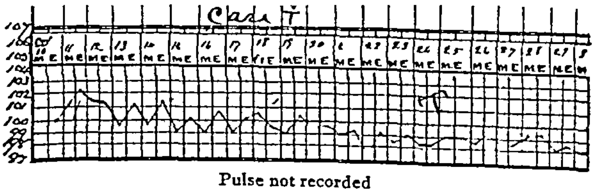
In this case the wound was enlarged upwards and downwards with scissors until it was about five inches in length, and seven pieces of bone were removed Two sharp points of bone were left at the junction of the lower and middle third of the tibia, which could not be retained in normal approximation These points were thereupon removed sufficiently to secure such retention of normal approximation The fragments were then wired together and dressed in the manner already described The further progress of the case is well illustrated in the accompanying chart



Pulse not recorded

It may be said that from time to time small fragments of tissue came away The fragments of bone approximated in the manner already described were denuded of periosteum, the upper fragment about an inch and a quarter and the lower about an inch, despite of this denudation, but little of either fragment exfoliated, as the denuded bone soon became permeated with blood-vessels and retained its vitality There was no resection of the fibula, the upper fracture of the latter perfectly united, the lower fracture did not, and two months after admission the lower fragment was drilled and has since united At present writing the patient seems likely to have a useful limb, without more than about half an inch of shortening The limb in such a case would usually have been amputated, since the extent of the injury would have been considered too great to permit of repair for a useful limb [1]

---

[1] Read in the Section of Surgery and Anatomy at the Thirty Sixth Annual Meeting of the American Medical Association

Second Proper retention of the fragments in place is presumably secured, thus avoiding any possible danger of the fragments overriding and injuring the soft tissues

Case 2—M S, single, sailor, 35 years old, of intemperate habits, was admitted to the Cook County Hospital on December 10, 1884 He has never had venereal troubles, but has been frequently attacked by intermittent fever, and on one occasion suffered from erysipelas The patient, while drunk, fell from a street car, sustaining a compound fracture of the skull over left eye, and a compound fracture of left humerus near neck, together with a lacerated wound of the left thigh and a contusion of left elbow

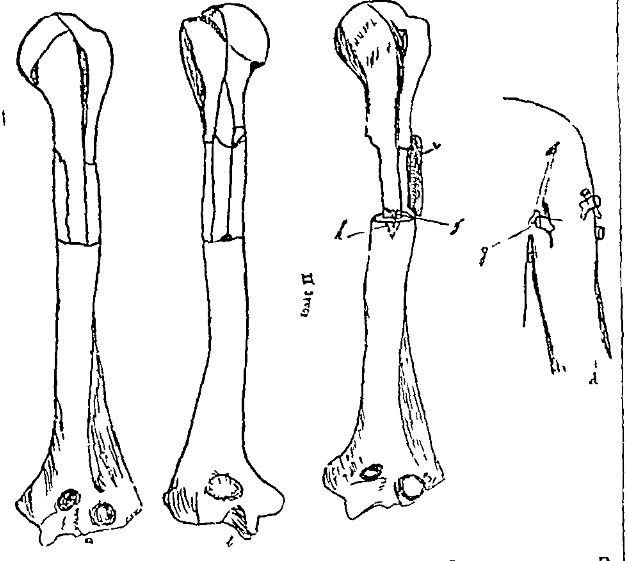


Figure 2—*A* anterior view *B* posterior view *C* anterior view *D*, anterior view of soft parts *F* remaining fragment. *F* dead bone removed March 1885 and wire *G* drainage tube ¾ in diam *H*, wire

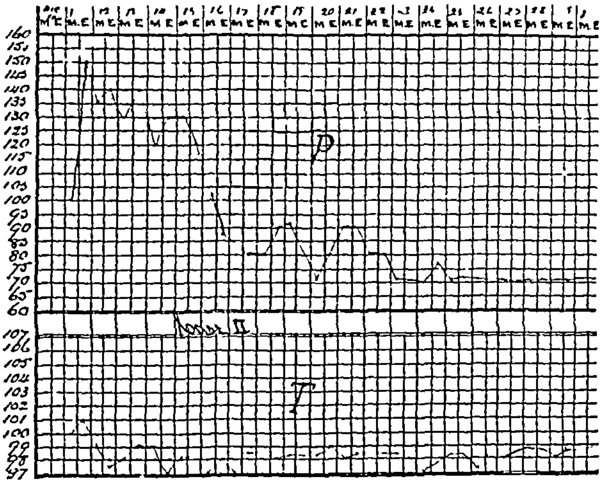
The wounds were dressed and the fractures treated in the way already described December 11, his morning temperature was 100° F, and his pulse 100, evening, 101° F, and the pulse 150 He was given eggnog and alcoholic stimulants

December 12, his morning pulse and temperature were 145 and 99° F Evening, 140 and 97 5° F, and there were given three grains of quinine and ten minums of tincture of per-chloride of iron thrice daily, as well as one-twentieth of strychniæ hypodermically On December 15 the leg was dressed; it looked well, no pus On the 16th the arm was dressed and there was much discharge of an offensive character, because of sloughing of the soft parts

December 21 the arm and leg were dressed and were looking well At the present writing patient is able to move the arm, but owing to a wound (rendered necessary to remove a fragment of bone and wire) which has not healed, he still keeps his arm in a sling Supination, pronation, flexion and extension are being regained by him He can raise the arm to an angle of sixty degrees There are no trophic or motor disturbances of the hand, which will show that no nerves have been permanently injured



The advantages of the procedure are well illustrated in this case One muscle, presumably the short head of the biceps, lay severed on the thorax The fracture began transversely at the upper portion of middle fifth, then extended longitudinally through the capsule About two inches of the upper fragment was fractured into four nearly equal parts, the most posterior fragment extended further upward in a V shape than the rest, the most internal and posterior fragments were nearly denuded of periosteum, and were removed, the most anterior fragment was attached to the head of humerus, was partly denuded and was left for mechanical support, the remaining fragment was not denuded and was retained The sharp corners of the anterior fragment were sawed off and it was inserted to the distance of half an inch in the medullary canal and wired, the other fragment

---

[1] Two months after admission two small shell like pieces of bone, which came one from each end and the wire were removed Two months later the patient left the hospital on pass and became intoxicated refracturing the bone which had been well supported by a strong cast One month subsequent to this an inch was resected from each fragment and these were joined by one wire Only one small drainage tube was used and but three dressings were needed During the next eight months he went out at intervals on pass always returning intoxicated About thirteen months after admission evidences of union were noticeable for the first time December 25 1885 an alarm of fire led to a very rapid flight on the part of the patient without the aid of crutches The leg swelled considerably Since that time union has gone on with great rapidity

The limb has regained its usual contour There is but two and a half inches shortening the ankle is somewhat immobile but this immobility is becoming less, and the patient is able to walk short distances without a cane was left free in close apposition It will be obvious that in this case the fracture was one in which many surgeons would regard an amputation as an absolute necessity[1] (See chart and figure 2)

Third There is no extension needed, which avoids the necessity of complicated apparatus and procedures such as too often interfere with proper antiseptic dressings

Case 3 —J C, aged 27, married, Irish, was injured August 30, 1884, by a hand car from which he was thrown He struck on one foot, the car running over leg The tibia and fibula were fractured, and there was also an extensive contusion of integument and muscles The same day he was admitted to hospital (twenty miles distant from the place where he was injured) The ends of the bones protruded and were covered by coal dust The fracture involved the lower part of the middle third of the tibia, which was fractured in three portions, the smaller being triangular A piece of bone an inch by half an inch was removed from the posterior part of tibia As the contusion was extensive, seven drainage tubes were inserted The fragments were wired together The triangular piece was wired to the upper by two wires which produced a notch or V shaped depression into wh ch the lower fragments fitted, to which it was then wired The lower end of the upper fragment was denuded of periosteum The temperature and pulse changes are best illustrated by the accompanying chart The patient recovered perfectly without deformity, the shortening being less than one-eighth inch The drainage prevented any extensive swelling of the tissues which must otherwise have resulted in considerable discomfort, independently of its influence in preventing blood poisoning (See bone chart) Latter part of November patient walked about the ward and did light work

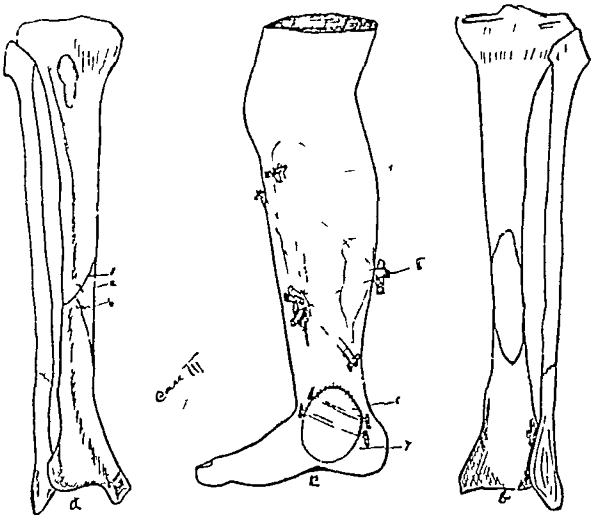


FIGURE 3 —*A* anterior view *B* posterior view *C* lateral view soft parts 1 2 3 wires 4 5 blood cavities beneath the subcutaneous tissue 6 flap of soft parts 7 position of soft parts on admission 8 drainage tube

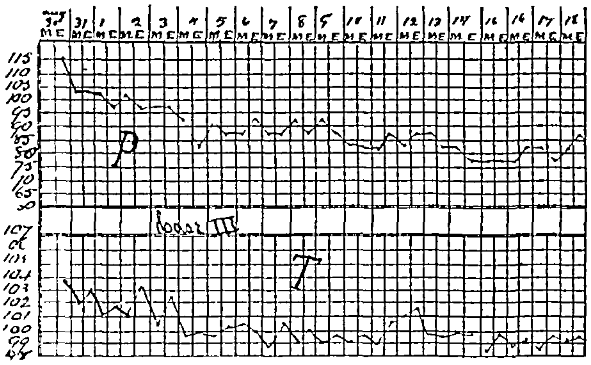

Fourth The bones unite quicker, for reasons which will be obvious when the principles which underlie all procedures to secure union of ununited fractures are recollected

Case 4 —I S, cigar maker, aged 51, moderate drinker, compound fracture of left leg The tibia was fractured obliquely upwards and backwards, about junction of lower and middle third The upper fragment protruded through the skin two inches and was denuded of periosteum to the extent of an inch and a half The lower fragment extended upwards and backwards from two to four inches The fibula was broken two inches above its lower extremity The projecting point of bone was sawn off, as it was denuded, very sharp, and likely to injure the soft parts, and was not needed for support The fragments were wired together (several blood clots had to be removed, as the soft parts were much contused), before twisting the wires A drainage-tube was passed through the gastrocnemius The limb was then dressed in the usual way The patient recovered with one fourth inch shortening[1] (See fever and bone charts)

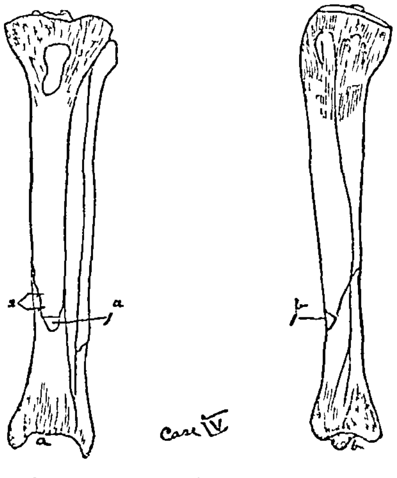

FIGURE 4 —*A* anterior view *B* lateral view 1 a, 1 b sharp point removed 2, wires

---

[1] June 20 1885 the patient was etherized and the depth of the pus pocket in the medullary canal determined to be seven inches The bone was trephined and a drainage tube inserted at the lower termination of the pus pocket The wound healed rapidly The patient spent the summer and winter between Chicago and Milwaukee, and used the arm for many purposes March 1886 he returned to the hospita and at his request two inches of bone were resected in order to so approximate the fragments as to secure union After the operation the fragments were united by two wires and drainage tubes inserted There has been no fever

---

[1] Recovery resembled that from simple fracture One-fourth of an inch shortening resulted The man is working at his trade

ments of tissue came away The fragments of bone approximated in the manner already described were denuded of periosteum, the upper fragment about an inch and a quarter and the lower about an inch, despite of this denudation, but little of either fragment exfoliated, as the denuded bone soon became permeated with blood vessels and retained its vitality There was no resection of the fibula, the upper fracture of the latter perfectly united, the lower fracture did not, and two months after admission the lower fragment was drilled and has since united At present writing the patient seems likely to have a useful limb, without more than about half an inch of shortening The limb in such a case would usually have been amputated, since the extent of the injury would have been considered too great to permit of repair for a useful limb [1]

Second Proper retention of the fragments in place is presumably secured, thus avoiding any possible danger of the fragments overriding and injuring the soft tissues

Case 2 —M S, single, sailor, 35 years old, of intemperate habits, was admitted to the Cook County Hospital on December 10, 1884 He has never had venereal troubles, but has been frequently attacked by intermittent fever, and on one occasion suffered from erysipelas The patient, while drunk, fell from a street car, sustaining a compound fracture of the skull over left eye, and a compound fracture of left humerus near neck, together with a lacerated wound of the left thigh and a contusion of left elbow

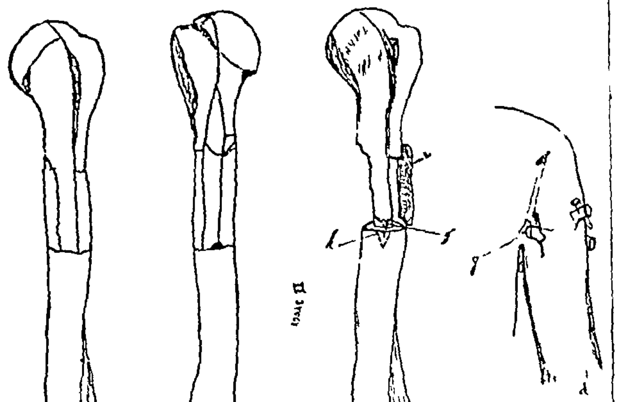

FIGURE 2 — *A* anterior view *B* posterior view *C* anterior view *D* anterior view of soft parts *F* remaining fragment. *F* dead bone removed March, 1885, and wire *G* drainage tube ¾ in diam *H* wire

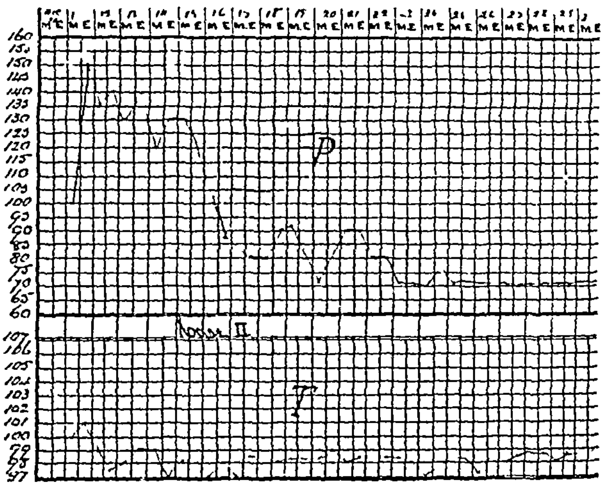
The wounds were dressed and the fractures treated in the way already described December 11, his morning temperature was 100° F, and his pulse 100, evening, 101° F, and the pulse 150 He was given eggnog and alcoholic stimulants

December 12, his morning pulse and temperature were 145 and 99° F Evening, 140 and 97 5° F, and there were given three grains of quinine and ten minums of tincture of per-chloride of iron thrice daily, as well as one twentieth of strychniæ hypodermically On December 15 the leg was dressed; it looked well, no pus On the 16th the arm was dressed and there was much discharge of an offensive character, because of sloughing of the soft parts

December 21 the arm and leg were dressed and were looking well At the present writing patient is able to move the arm, but owing to a wound (rendered necessary to remove a fragment of bone and wire) which has not healed, he still keeps his arm in a sling Supination, pronation, flexion and extension are being regained by him He can raise the arm to an angle of sixty degrees There are no trophic or motor disturbances of the hand, which will show that no nerves have been permanently injured



The advantages of the procedure are well illustrated in this case One muscle, presumably the short head of the biceps, lay severed on the thorax The fracture began transversely at the upper portion of middle fifth, then extended longitudinally through the capsule About two inches of the upper fragment was fractured into four nearly equal parts, the most posterior fragment extended further upward in a V shape than the rest, the most internal and posterior fragments were nearly denuded of periosteum, and were removed, the most anterior fragment was attached to the head of humerus, was partly denuded and was left for mechanical support, the remaining fragment was not denuded and was retained The sharp corners of the anterior fragment were sawed off and it was inserted to the distance of half an inch in the medullary canal and wired, the other fragment

---

[1] Two months after admission two small shell like pieces of bone which came one from each end and the wire were removed Two months later the patient left the hospital on pass and became intoxicated refracturing the bone which had been well supported by a strong cast One month subsequent to this an inch was resected from each fragment and these were joined by one wire Only one small drainage tube was used, and but three dressings were needed During the next eight months he went out at intervals on pass always returning intoxicated About thirteen months after admission evidences of union were noticeable for the first time December 25 1885 an alarm of fire led to a very rapid flight on the part of the patient without the aid of crutches The leg swelled considerably Since that time union has gone on with great rapidity

The limb has regained its usual contour There is but two and a half inches shortening the ankle is somewhat immobile but this immobility is becoming less, and the patient is able to walk short distances without a cane was left free in close apposition It will be obvious that in this case the fracture was one in which many surgeons would regard an amputation as an absolute necessity[1] (See chart and figure 2)

Third There is no extension needed, which avoids the necessity of complicated apparatus and procedures such as too often interfere with proper antiseptic dressings

Case 3—J C, aged 27, married, Irish, was injured August 30, 1884, by a hand car from which he was thrown He struck on one foot, the car running over leg The tibia and fibula were fractured, and there was also an extensive contusion of integument and muscles The same day he was ad mitted to hospital (twenty miles distant from the place where he was injured) The ends of the bones protruded and were covered by coal dust The fracture involved the lower part of the middle third of the tibia, which was fractured in three portions, the smaller being triangular A piece of bone an inch by half an inch was removed from the posterior part of tibia As the contusion was extensive, seven drainage-tubes were inserted The fragments were wired together The triangular piece was wired to the upper by two wires which produced a notch or V shaped depression into which the lower fragments fitted, to which it was then wired The lower end of the upper fragment was denuded of periosteum The temperature and pulse changes are best illustrated by the accompanying chart The patient recovered perfectly without deformity, the shortening being less than one-eighth inch The drainage prevented any extensive swelling of the tissues which must otherwise have resulted in considerable discomfort, independently of its influence in preventing blood poisoning (See bone chart) Latter part of November patient walked about the ward and did light work

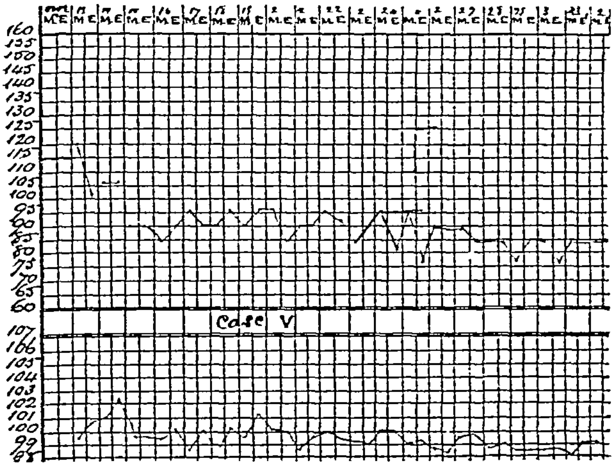
[1] June 20 1885 the patient was etherized and the depth of the pus pocket in the medullary canal determined to be seven inches The bone was trephined and a drainage tube inserted at the lower termination of the pus pocket. The wound healed rapidly The patient spent the summer and winter between Chicago and Milwaukee and used the arm for many purposes March 1886 he returned to the hospita and at his request two inches of bone were resected in order to so approximate the fragments as to secure union After the operation the fragments were united by two wires and drainage tubes inserted There has been no fever

[1] Recovery resembled that from simple fracture One-fourth of an inch shortening resulted The man is working at his trade



(Error in chart—should be marked IV)

Fifth As a rule, it will be apparent that there can be little if any shortening

Case 5 —G T S, married, white, aged 41, weight 225 lbs, heavy drinker, has had syphilis twenty years ago Was admitted to the Cook County Hospital November 21, 1884, having fallen from a fifth story scaffolding and struck on one foot, causing a compound comminuted fracture of right leg On examination it was found that the tibia was fractured obliquely (see cut 5), the line of fracture being four inches, and the fragments protruded markedly through the soft parts, which were very much lacerated

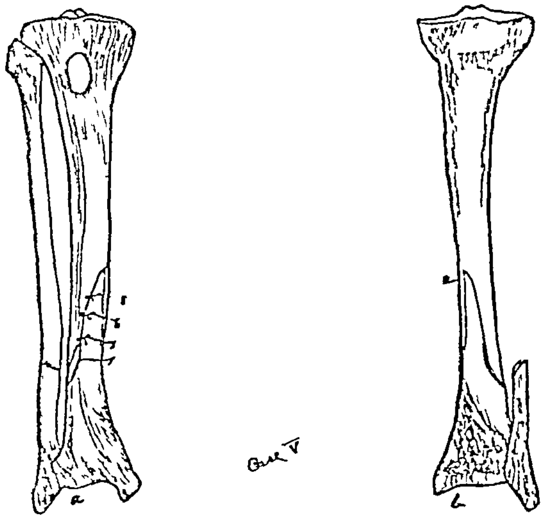


Figure 5 —A anterior view B posterior view 1 2 fragments removed on admission 5 6 7 wires

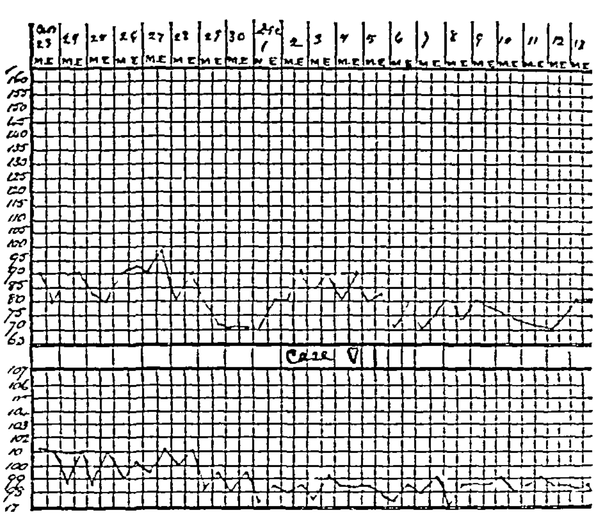
The fibula was fractured transversely and the foot could be bent at right angles with the leg without resistance This was treated in the way already described, and the progress of the case towards recovery was only interrupted November 29, by a marked sloughing of tissues around the original wound, and on December 1 more sloughing occurred, causing the loss of substance, skin and cutaneous tissue in calf of leg three inches by four The patient thereafter did well and was discharged nearly recovered April 1, there being a possibility of a small piece of bone to be removed [1] (See figure and chart)



Sixth Drainage prevents inflammation by preventing the accumulation of fluids, as in cases 1, 2 and 3

Case 6 —A S, aged 45, moderate drinker In this case the left tibia was fractured as shown in cut VI, and there was a small external opening through the integument

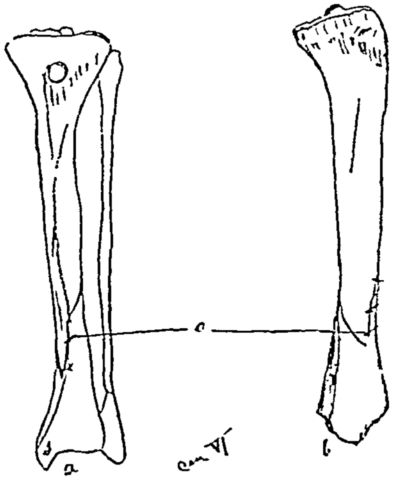


Figure 6 —A anterior view B lateral view C wire

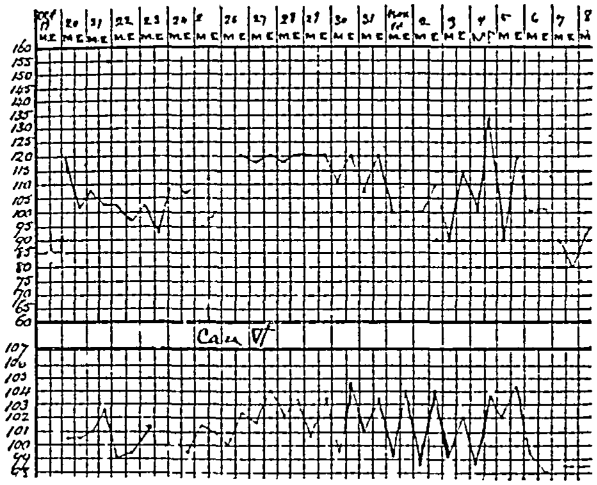
The fragments were not comminuted, but an extensive hæmorrhage which had occurred led to an enlargement of the external wound, and showed that the posterior tibial artery had been nearly severed by a sharp point of bone The artery was tied and the fragments wired, and the wound treated in the usual way Pyæmic symptoms set in and were followed by symptoms of gangrene necessitating amputation, after which the patient made a good recovery [1]

---

[1] April 1885, patient left the hospital against advice There was an eighth of an inch shortening There was a small opening The limb had a good contour and union was apparently good as the leg would sustain much weight The patient a chronic inebriate returned within three weeks suffering from erysipelas which was followed by abscesses in thigh knee joint and leg The foot became markedly extended and ankle joint limited in motion He reëntered the surgical ward within three weeks much emaciated In an attempt to flex the foot the leg was refractured September 1885 the ends of the fragment were chiseled till the ends could be approximated and then joined by two nails Good union followed The leg tissues were flabby He has since had three recurrent attacks of erysipelas The leg muscles are much emaciated The ankle joint is rather stiff but improving The patient can put some weight on the foot Shortening one half inch



Case 7—F W B, policeman, aged 27, moderate drinker, has had venereal disease, was shot in anterior part of left leg and after injury attempted to use limb There was a circular opening about the size of a nickle, extending down to the bone, from which a slight active hæmorrhage occurred The wound was over the left tibia about the lower part of the middle third The tibia was fractured in the way indicated in figure 7 The upper fragment being split in two, and the fibula was also fractured

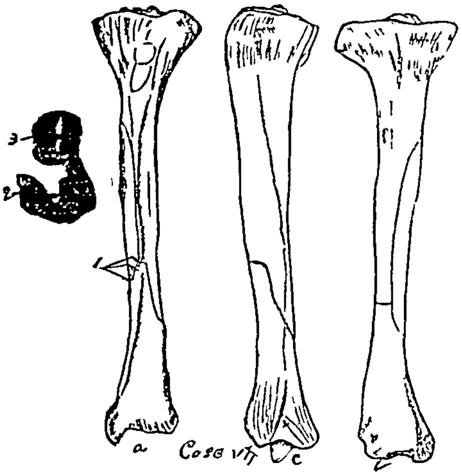


FIGURE 7—*A* anterior view *B* posterior view *C* lateral view
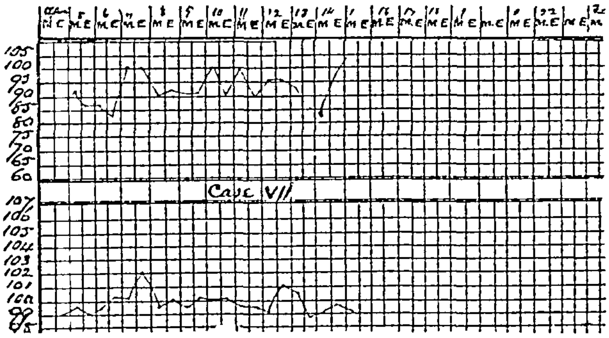
1 wire 2 cloth 3 bullet

A longitudinal incision was made four and one-half inches in length, through the skin to the bone, the flattened bullet and a fragment of cloth lay about two inches from where the bullet struck Very efficient drainage was made by a moderate sized tube The fragments were then wired, as in Case 3 With the exception of the parts much contused by the bullet, the wound healed by first intention The patient bids fair to make an excellent recovery [1]



Case 8—J C, white, laborer, aged 40, fractured leg, (compound) The wound was at the lower third of the leg, the tibia was fractured into five pieces, and there was an oblique fracture of the fibula The fracture communicated externally in three places

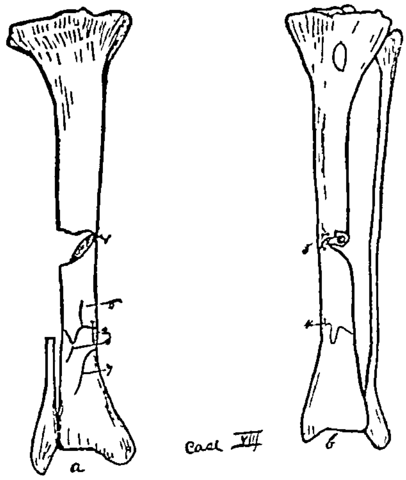


FIGURE 8—*A* anterior view *B*, posterior view 1 2 3 4 wires
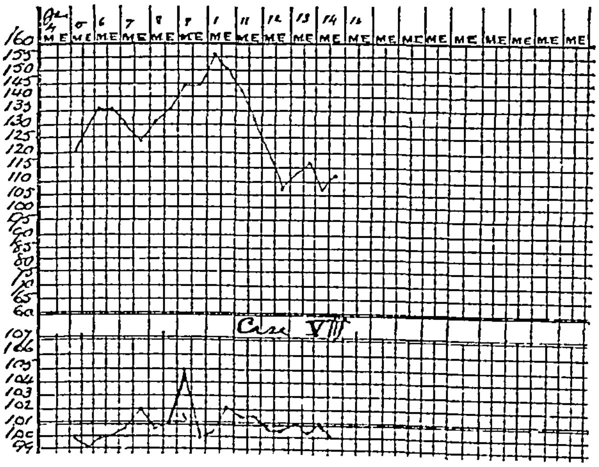
6 and 7 fissures



---

[1] No further history obtained

[1] Recovered with between half and a third of an inch shortening During my absence an attempt was made to put on an interrupted cast The wires broke through the fragments became dislocated and numerous ulcers resulted from iron bar in cast Fragments re approximated and re wired

There were several loose pieces of bone removed and the parts surrounding the fracture were severely contused The fragments were wired together, but extensive sloughing of the soft parts occurred and amputation was found to be necessary five days after admission, the patient dying five days later

This case certainly does not militate against the procedure, as it would have been a desperate one under any circumstances [1] (See figure and chart)

OCCLUSION OF THE FALLOPIAN TUBE, DYSMENORRHŒA, WITH CONVULSIONS AND OPISTHOTONOS—LAPAROTOMY, RECOVERY

BY R STANSBURY SUTTON, A M, M D, LL D,
OF PITTSBURG PA
FELLOW OF THE AMERICAN GYNECOLOGICAL SOCIETY OF THE BRITISH GYNECOLOGICAL SOCIETY ASSOCIATE FELLOW OF THE PHILADELPHIA OBSTETRICAL SOCIETY MEMBER OF THE BRITISH MEDICAL ASSOCIATION PRESIDENT OF THE AMERICAN ACADEMY OF MEDICINE ETC

Mrs R, an American lady, aged 31 years, was confined with her only child in 1876 Her labor was followed with an attack of cellulitis, especially severe on the right side For seven years her menstrual periods were painful, and for the last two and a half the pain has been accompanied with convulsions Her menstrual periods became more and more trying and the pain in the right groin extending down into the leg and rendering locomotion difficult, increased in intensity from month to month After enduring this disturbance for nine and a half years, she consulted me near the end of 1885

Examination—Dorsal decubitus, perineum, partial laceration, cervix uteri, bilateral laceration Vaginal walls relaxed, cervical and vaginal leucorrhœa Neither of the ovaries could be distinctly felt The portion of the vaginal vault on the right of the uterus was tender to the touch, and to this region she referred the pain she experienced during her menstrual periods After this examination she returned home, and continued douches of hot water and counter-irritation over the right inguinal region until February 8 1886, when she became an inmate of my private hospital She reported that her distress at the time of her menstrual periods had increased since her visit to me near the close of the preceding year Ten days after her admission she menstruated, and the pain she experienced during this period resisted all reasonable doses of morphia administered subcutaneously An examination during the flow discovered, in the right side of the pelvis, a mass as large as a guinea egg and extremely sensitive Morphia hot douches, local blisters and rest in bed were persisted in during the continuance of the flow, and when it ceased, it left her lame in her right leg for several days Three days after the termination of the flow, the mass discovered a few days previous could not be felt

Nine days subsequent to the cessation of the menses and after six of comfort, the pain in the right inguinal region returned, it extended down the leg on that side and rendered locomotion difficult and painful Bimanual examination revealed the mass again present, situated on the right of the uterus and almost directly behind the external inguinal ring It was not as large as it was during the flow, but fully as painful to the touch Three days later it had again disappeared Churchill's tincture iodine was liberally used over the vault of the vagina, local blisters applied, the hot douches were doubled in number and quantity and the temperature of the water raised to 115–120°, and absolute rest in bed required On the morning of March 14 her second menstrual flow came on unannounced by pain Twenty four hours later a sudden invasion of agonizing pain occurred, and before sufficient morphia to relieve her sufferings could be administered, she had six convulsions, and stood on her head and heels, her body arcuate—perfect opisthotonos Within a few hours nearly 2 grains of morphia were administered subcutaneously, producing no apparent effect Fearing a fatal result from the exhibition of the narcotic, chloral hydrates and bromides in large doses were substituted The hot douches were continued and a blister applied over the right inguinal region The mass in the pelvis was now apparent to the touch and very sensitive to pressure On March 19, after four days of severe suffering, the flow ceased, and in three days more the mass in the pelvis had again disappeared

Diagnosis—I could make none Chronic cellulitis, recurring attacks of acute cellulitis, or local peritonitis was evident, but why? Was there pus, or blood in the tube? Possibly, but why no evidence except the pain and the mass alternately appearing and disappearing? Her leucorrhœal discharges might contain pus, I did not delay to examine with the microscope, this I could do afterwards I reasoned that this trouble was of long standing, steadily and rapidly increasing, and I decided to open her abdomen, discover the cause, and do all I could to save the life of the lady I agree with Mr Tait in the matter of opening the abdomen for exploration in certain cases A diagnosis without this is not always possible, and the surgeon who delays operation until a diagnosis is made, will be often in error, and his usefulness is limited

On the 22d of March the bowels of this woman were cleaned out, and on the 23d, at 2 P M, she was placed on the operating table and anæsthetized by the second nurse Dr Stone, my assistant, being necessarily absent, I assigned my chief nurse to his place I then proceeded to open the abdomen with an incision a little short of three inches, and discovering a difficult operation awaiting me, I lengthened the incision to five inches Through this I turned the intestines out upon a towel above the upper angle of the opening, and gave them into the care of the nurse An adhesion on the tip of the omentum was detached from something in the pelvis I then discovered that the ovary and tube on the right side were firmly adherent to each other, to the broad ligament and the roof of the vagina, with great difficulty they were released with the fingers and drawn into view The pedicle was secured with Tait's knot, and the ovary and tube cut away. The left ovary was small, and both it and the tube appearing to be free from disease, they were not disturbed. The cavity was cleansed, the intestines replaced, the wound closed and the patient returned to bed. Carbolic acid did not touch the patient during the operation, and scalding water alone was used for the instruments and ligatures. The technique as pertaining to cleanliness was satisfactory. Drs. Lee, of Rochester, N. Y., and T. B. La Rue, of Smith's Grove, Ky., were present as visitors and witnessed the operation. I follow Mr. Tait in relying alone on hot water. No carbolic acid touches my patients.

---

[1] *The patient's breath* on admission smelled of whisky and during his entire hospital sojourn he appeared dazed The tissues were bleeding but sloughing did not seem likely to occur the shock from an amputation would have been greater than from the procedure adopted We had no post mortem urine was not tested exact cause of death not known

Examination of the parts removed.—The ovary was twice the ordinary size and cystic. It contained a large proportion of healthy ovarian stroma, which was here and there crossed with fine lines of gritty tissue. An empty ovisac lay beneath the surface, ruptured, and proved that true ovarian action existed immediately prior to the operation. The tube was entire, with the exception of the fimbriated end; this was torn and a small portion of it absent. It exhibited the usual appearance, except a redder color. Its calibre was normal, except at the ulterior end, where it was occluded by a stricture so complete that the head of a needle used as a probe could not be passed through it.

Rationale of symptoms.—The stricture in the tube doubtless arrested the ova, and to some extent accounts for the symptoms, but, in my judgment, had the ovary been free, this would not have caused pain. The ovary was bound to the fimbriated end of the tube and the surface of the broad ligament, and at the menstrual periods, its physiological increase was impeded; its products were imprisoned in the surrounding tissue, and the pain was largely caused by the pressure thus produced. During menstrual activity the mass appeared, and disappeared when it subsided. Its recurrence subsequent to the cessation of the flow, I suspect, was due to the excitement in the ovary during ovulation, which certainly occurs independent of menstruation.

Result.—On the day following the operation, the pulse was 108, and the temperature 100¼°; the next day both the pulse and temperature fell below 100. On the fourth day the stitches were removed. On the morning of the fifth day the pulse was 74, and the temperature 99°. On the morning of the sixth the pulse was 65, and the temperature 98½° (Fahrenheit). No farther rise in the temperature occurred, and her progress was rapid. From this date no further attention than that given by her nurse was required. She left the hospital for home on April 16; she had not as yet menstruated.

Remarks.—Does this case prove that, as gynecological surgeons, we are too aggressive? Does it prove that exploratory operations are useless and dangerous? So long as proper precautions as to place of operating and environment are observed, such operations will bring neither harm to the patient nor obloquy to the art. Of my last forty-one abdominal sections, none has given me less anxiety and more pleasure than the one just described. A new lease of life is this woman's reward for her confidence in me and my regard for duty.

NINE CASES OF IMPERMEABLE URETHRAL STRICTURE TREATED BY ELECTROLYSIS

BY WM. T. BELFIELD, M.D.,
GENITO-URINARY SURGEON TO THE COOK COUNTY HOSPITAL, CHICAGO.

The removal of urethral stricture by a galvanic current is a method of treatment whose merits and advantages have been generally ignored by specialists as well as by general practitioners. In very few of the standard text books is this method even mentioned, and in none that I have seen is it intelligently discussed. A few physicians have, at various periods in the past thirty years, briefly tried and then abandoned the current; and the report of their failures had deterred others from further investigation.

Unfavorable and even disastrous results have undoubtedly been produced by electrolysis; but they have generally been caused by the use of an improper current. To dissolve the cicatricial tissues constituting a stricture only the chemical, dialytic effect of the current is required or desired. Now the galvanic current liberates heat as well as chemical force; it will not only decompose a chemical compound, but will also raise a platinum wire to a white heat. The ill effects of the current observed in the urethra have evidently been produced by the heat; as formerly applied, the treatment of stricture by the current was in effect merely a cauterization of the urethra, which resulted of course in severe local inflammation and even extensive sloughing. Yet by proper management a galvanic current can be made to produce a strong chemical effect with an insignificant minimum of heat; or, in technical language, to produce great *intensity* with but little *quantity*. To this end the plates should be small and the fluid weak, but a number of cells (6 to 15) should produce the current.[1] To Dr. Robert Newman, of New York, is due great credit for urging upon the profession the proper use of the current for electrolysis.

During the past two years I have practiced electrolysis for stricture upon thirty-seven patients; and I now use it almost exclusively except for strictures located within an inch of the meatus, and for strictures of large calibre elsewhere in the penile urethra (which I divide with Otis's urethrotome). In my experience the advantages of this method may be summarized as follows:

1. It is applicable to strictures at any point in the urethra.
2. Any stricture or succession of strictures, however rigid and cartilaginous, however long and tortuous, however tight (even if impermeable), can be readily and safely perforated.
3. As a rule it causes no pain nor bleeding, is followed by no chill nor urethral fever, and it is always devoid of danger.
4. When properly handled it can produce no false passage nor other local lesion.
5. The effects are more enduring than those of either cutting or stretching; whether or not they are permanent (as maintained by Dr. Newman), my experience does not yet enable me to assert.

---

[1] For the past year I have used with great satisfaction the complete and compact portable battery made by the McIntosh Company, 300 Dearborn Street, Chicago.

Even in the treatment of permeable strictures, therefore, electrolysis is generally far preferable to the usual methods, urethrotomy and dilatation Thus internal urethrotomy should never, under any circumstances, be performed in the membranous urethra, if made in the penile portion when the stricture is very tight, or very long, or very firm, the operation is usually followed by severe fever and local inflammation, occasionally even by death Dilatation is unsatisfactory—aside from the attendant pain and tendency to induce urethral fever—because its effects are transient, and especially because it is inefficient in numerous cases We are often called to treat men of middle or advanced age suffering from old and rigid strictures, which are perceptible from the external surface as large, irregular, cartilaginous masses Every attempt to dilate in these cases is apt to cause a chill and fever, and when this has subsided the surgeon finds the stricture just as rigid and as tight as before Electrolysis removes these strictures without producing urethral fever

There are, however, numerous cases of stricture for which electrolysis is not merely preferable to urethrotomy and dilatation, it is, indeed, the only treatment practicable These cases may be divided into three classes

1 Impermeable strictures without complete retention of urine I have treated four such cases where the strictures were impermeable to even the finest instruments, though the patients were still able to force a little urine through them In each case a No 12 French bulb was passed into the bladder without difficulty, and the patients were immediately relieved from the annoying frequency and pain of urination In none of these cases did any chill, urethral fever or other constitutional disturbance follow the operation

2 Impermeable strictures with complete retention I have treated by electrolysis three such cases, in each of which the bladder was distended to or above the level of the umbilicus One was a traumatic stricture following rupture of the membranous urethra by a blow upon the perineum, in one of the others the strictures (of gonorrhœal origin) were scattered along the urethra from meatus to prostate In each of these I succeeded in passing a No 10 bulb (French) into the bladder at the first sitting, and to insert a catheter immediately *Each of these patients was therefore saved from a perineal section, which would otherwise have been inevitable* One of the three, who had an elevation of temperature previous to the operation, experienced a severe chill and violent fever within the first twenty-four hours, but was entirely recovered on the third day The other two showed no reaction

3 Tight and rigid strictures (permeable or otherwise) with perineal or scrotal fistulæ I was privileged to see and report a most interesting case of this sort treated by my friend Dr Truman W Miller A man 34 years old presented himself to Dr Miller suffering from numerous rigid strictures involving nearly the whole urethra from the middle of the penile portion to the prostate, not even a filiform bougie could be made to enter the bladder The perineum and scrotum were literally honeycombed with fistulæ, there being, according to the patient's census, twenty-seven openings, through which urine was discharged as if from a watering pot, scrotum and perineum were thickened and indurated The patient was compelled to urinate every half hour or less, rising fifteen to eighteen times at night He had been under treatment by different surgeons for five years, had submitted to both external and internal urethrotomy, as well as numerous attempts at dilatation For two years past he had been an invalid, devoting his whole time and attention to constant efforts at emptying the bladder At the first sitting Dr Miller passed a No 10 bulb (French) into the bladder, the patient experienced no febrile reaction, but for the first time in several years passed a fair stream from the meatus The urine no longer flowed through the fistulæ, and the patient was compelled to rise only once or twice at night At a second sitting a No 12 French easily entered the bladder

The permanence of effects produced by electrolysis is indicated in the following case In February, 1885, a young German was admitted to the County Hospital, suffering from complete retention of urine caused by an impermeable traumatic stricture of the membranous urethra I performed perineal urethrotomy without a guide, and passed a No 14 sound (English) into the bladder Patient recovered nicely, but in spite of the regular passage of sounds, the stricture rapidly contracted again, until in May (three months after operation) it scarcely admitted a No 4 I then commenced using upon it the galvanic current, and in six sittings raised the calibre to No 12 English Since that time (July 1, 1885) he has experienced no difficulty in urinating, and his urethra readily admits No 11

612 Opera House Block

A CASE OF SYMBLEPHARON OF THE LOWER EYE-LID, WITH OPERATION[1]

BY ARNOLD P GILMORE, M D,

OF CHICAGO, ILL

My patient, Mr Shirley, has kindly consented to appear before the Society this evening He belongs to that large class of persons who suffer from burns caused by caustics, hot metals, etc, and has what may be called complete symblepharon of the left lower lid His case is of interest, I think, to those who do work in plastic surgery, and more particularly in surgery involving tissue that has been burned, and has consequently become cicatricial

The tissue af the eye-lid is such that very slight injuries will cause disturbance of its functions, and deformities This is particularly true of injuries due to burns Mr Shirley's left eye was severely burned with hot iron four years ago He was treated by a layman for two weeks, and then consulted an oculist The lid had by this time grown fast to the eye ball to a considerable extent Some operation was performed, but no permanent benefit followed The operation was repeated three times at intervals of several weeks, the lid being detached each time and some plastic operation performed None of these operations proved to be successful

---

[1] Read before the Chicago Medical Society, March 15 1886 with exhibition of patient

I first saw the patient about nine months ago The entire lower lid, from external to internal canthus, was then adherent to the eye-ball, covering almost the entire cornea, save a small portion at the upper margin This triangular-shaped tissue was covered by a pale membrane, neither a true skin, nor a true mucous membrane, and I found upon cutting into it that it was composed of cicatricial tissue, very dense and difficult to separate

My first operation was performed under cocaine, which was ineffectual for so extensive a dissection, and the patient was very restless, increasing greatly the difficulty of the operation I detached the lower lid and transplanted the conjunctiva of a rabbit to the eye ball For six weeks this operation was apparently successful At this time I left the city and was absent about two months On my return I was amazed to see the lid fast assuming its original location on the eye ball

Six weeks ago I performed the second operation, under ether I made a thorough dissection, freeing the lid entirely, and making a deep cul de sac This, as you see, would leave the upper half of the eye-ball covered with mucous membrane, and the lower half uncovered I then dissected a semi-circular band of conjunctiva, about one-third of an inch wide, around and close to the cornea above, leaving a bridge at each end This band I dropped into the cul de sac below and carefully stitched it to the ball

In order to prevent adhesions, for it is characteristic of this cicatricial tissue to grow underneath and crowd out everything above it, I anchored a silver rope an eighth of an inch thick and one inch long in the bottom of the cul de sac by bringing a free strand from either end of this rope through the cheek and tying them together In spite of this, there was a tendency to form adhesions at both canthi I threw a silver ligature around these adhesions, and tried to slowly constrict them But the process was slow and painful, as well as very doubtful I then had a semicircular plate of silver made, long enough to fill the space between the external and internal canthi, with two holes at the circumference one-half inch apart, which I threaded with silver wires I removed the silver rope, which had, by the way, become encysted, and its removal was attended with considerable bleeding and pain I cut all adhesions and sunk the silver plate into position by bringing the wires through upon the face and fastening them by small lead plates and perforated shot I claim priority in this method of fastening the plate

The object of this operation is neither the improvement of the appearance of the injured eye, nor to restore its vision, but to relieve the irritation of the other eye As may be readily understood, if one eye ball is securely anchored to the lid the coordinate action of the two eyes is interfered with, and the sound eye becomes weakened In this case, in order to preserve the health of the other eye, it had become absolutely necessary either to free the eye ball or enucleate it

There were two good reasons why I did not advise enucleation 1st There is enough clear cornea in this eye to make a small artificial pupil, if he should ever lose the sight of his right eye 2d He could never wear a glass eye, and he would be disfigured to that extent

Only very slight reaction followed these operations, and at no time has there been much pus I used cold water compresses and kept the wound perfectly clean The sound eye has grown stronger in the last few days, in spite of the presence of the silver plate, and I am encouraged to believe that the result of the operation will be good

MEDICAL PROGRESS

VIBURNUM PRUNIFOLIUM (BLACK HAW) IN ABORTION AND MISCARRIAGE —MR JOHN HENRY WILSON, of Liverpool, says "In the number of the *Liverpool Medico-Chirurgical Journal* for January, 1885, I reported six typical cases treated successfully by this medicine, and since then, after considerable experience, I have been more and more confirmed in its value I cannot say it has always succeeded, but in those cases in which it failed, I have been able to account for its doing so Either the medicine has not been commenced in time, and the ovum has been detached before the viburnum has been taken, or there has been some reason to suspect a syphilitic taint, and, in a case of fatty degeneration of the placenta, after not succeeding with the viburnum alone, chlorate of potash was taken in addition, with a good result

Dr Napier says "some women abort on the slightest provocation," and they continue to do so, although every care may have been taken in the way of rest, medicine, etc, to prevent it I have had many such cases, and have been greatly disappointed, but when I have had the opportunity of commencing the viburnum shortly before the anticipated period, and continued it at intervals on the first appearance of threatening symptoms, these patients have invariably gone on to the full time, and done well, without being subjected to restrictions or debarred from active exercise

In the next class of cases, where there may be reason to suspect even a partial separation of the ovum and a dilated external os, with severe pains and hæmorrhage going on for hours, and the patient under the impression that she could not possibly go on to her full time, and when I had almost despaired of any benefit from the medicine, I have been astonished at its effect, more than three fourths of these cases doing well

The most sanguine advocate of viburnum could not expect it to do impossibilities, or to prevent abortion when there is "a gaping os, and a detached ovum presenting" One might as well expect to resuscitate a dead body by galvanism I have never seen ill consequences follow the administration of the medicine, however often the dose has been repeated In two cases only has it been followed by slight headache. One patient inquired if she had not been taking quinine. The symptoms had been relieved, therefore it was not continued. In the other case, the patient had taken 4 grains of the extract every two hours. The only change was to extend the interval to four hours, and then gradually discontinue it. Some patients have taken viburnum at intervals during the whole course of their pregnancy. It seems to act as an uterine tonic and sedative, and to relieve the woman of those harrassing nervous forebodings which often lead to abortion. The patient, after taking only a few doses, has quite a changed expression. From a drawn, desponding look, her countenance becomes cheerful and happy. Since I have prescribed viburnum, it has not been necessary to keep the women in the horizontal position more than a few days, whereas, under the old treatment, they occasionally spent weeks in bed, and, after all, abortion has taken place. On some of the plantations in America, it is the popular belief that a woman cannot abort if she be under the influence of black haw, although she may be taking medicine with a criminal intent. My experience would go far to confirm that opinion, for I have had patients in whom a succession of abortions have taken place, but, when under the influence of the medicine, they have been able to resist the severest tests—frights, falls, strains, etc.—and no ill effects have followed.

With regard to the mode of administering the drug: at first, the liquid extract was ordered, but the smell was so strong and objectionable that the whole house became impregnated, and in two cases, where the stomach could not retain it, the liquid was given as an enema. I now order the extract in pills of 4 grains, and find it a convenient form, as usually made, they soon absorb moisture, and run into a mass, but I now advise them gelatine coated. These pills keep any length of time, and I advise my patients to keep a supply by them. I have such confidence in viburnum prunifolium that I am anxious the profession should give it a trial, feeling assured they will not be disappointed.—*British Medical Journal*, April 3, 1886.

THE TRACTION TREATMENT OF MORBUS COXARIUS.—DR. LANNELONGUE, Surgeon at the Trousseau Hospital, recently read notes before the Paris Surgical Society on the method of traction by the application of weight and continuous extension in treating articular affections, especially strumous hip joint disease. Le Sauvage, of Caen, described in 1830 this method of treatment, but the American surgeons were the first to realize its importance, and to endeavor, by the aid of different apparatus, to keep the head of the femur from contact with the acetabulum. A child, 4 years old, in M. Lannelongue's wards, died in the early stage of hip joint disease, its limbs had been under the influence of extension since Oct. 22, 1885, a weight of two kilogrammes, increased to three, had been employed. The apparatus was removed four days before the child's death from croup. An experiment on the dead body was made during a severe frost, and the body was perfectly preserved. The pelvis was separated from the trunk and fixed to a plank by nails, the vertebræ and the ilia being firmly secured. The hip joint was left thoroughly free, so that flexion, extension, and rotation outwards could be effected without hindrance. Extension was practised as on the living body. The weight attached was four kilogrammes. The experiment commenced at 10.30 A.M., and was continued until 7 P.M. Rigor mortis was absent. The operating room was heated to about 77° Fahr. The limb was frozen with salt and ice, and afterwards with salt and hydrochloric acid. At nine o'clock next morning, the limb was as hard as wood. A section was made with a saw in the direction of the neck of the femur. The relations of the contiguous parts were not disturbed. It was easily observed that the articular surfaces were not in contact with each other, there was an interval of half a centimètre between them and the centre of the joint at the highest point. The cartilage of the head and the lower part of the articulation were in contact. The capsular ligament was strained over the head of the femur, and lay close against it, but in the upper part, the space existing between the articular surfaces was filled with a soft fungoid growth. The head of the femur had slipped downwards, one half, which was not flattened like the upper part, but rounded, lay beyond the cotyloid cartilage. This experiment showed that the separation of the articular surfaces was an actual fact. It must be remembered that this result was due to the application of extension forty five days before death, not to that practised on the dead body. Nearly the entire capsular ligament had degenerated into fungoid growth, and was unable to resist the influence of traction. M. Verneuil said that M. Lannelongue's experiment explained a fact that had recently come under his notice. On examining a patient with a very severe form of hip joint disease, he observed that the limb was shortened, and that the great trochanter was displaced upwards. He supposed that there was incomplete dislocation, and decided on practising resection. He then found the head of the femur lying in the acetabulum. It must be concluded that, at a certain period of this disease, the femur becomes deformed, and presents the characteristics of partial dislocation. In future, an apparent shortening, even of three centimètres, accompanied by a moving upwards of the great trochanter, should not warrant the conclusion that the head of the femur is really dislocated.—*London Medical Record*, March 15, 1886.

PAPAIN IN DYSPEPSIA.—DR. GEORGE HERSCHELL, in a note on this subject, says that he finds papaïn chiefly valuable in the following classes of cases:

1. *Chronic Stomach Catarrhs of Children.*—Every one of us is familiar with that state in which we find children at times, and which is very frequently called "biliousness." It is characterized by loss of appetite, languor, pasty complexion, loss of sleep at night, and irritability during the day. There is frequently frontal headache, and the urine is loaded with lithates. If this state continue for any length of time the child emaciates, the unhealthy mucus which sheathes the stomach and intestines preventing the due absorption of the food. Cod-liver oil and compound syrup of

the phosphates, which are generally given for the complaint as soon as the child begins to lose flesh, are not assimilated Sometimes a cough develops, and the child is supposed to have incipient phthisis I have found these cases rapidly improve with the following prescription

℞	Papain (Finkler)	gr ½–gr j
	Sach lactis	gr j
	Sodii bicarb	gr v
	M To be taken after every meal	

It is also advantageous to give a drop or two of tincture of nux vomica immediately after the meal in a little water The papain probably acts by dissolving the mucus, and thus facilitating the absorption of the food

2 *Acid Dyspepsia* —This drug is extremely valuable in this form of indigestion *a* As it acts equally well in the presence of an alkali, a sufficient quantity of bicarbonate of soda may be given with it to neutralize the excess of acid in the stomach without impairing its peptonizing power *b* Its antiseptic action checks the abnormal fermentation to which much of the accompanying flatulence is due *c* An antiseptic can be given with it to increase this action I usually order it in the following manner

℞	Papain (Finkler)	gr ij
	Sach lactis	gr v
M	To be taken an hour after meals with the following draught	

℞	Sodii bicarb	gr xv
	Glycerin acid carbolic	m viii
	Spirit ammon aromat	m xx
	Aq ad	℥iss
	M Fiat haustus	

It appears that, taken one hour after a meal, a smaller dose of papain is required to produce the same result than if taken with the food

3 *Cases where Severe Gastric Pain coming on Shortly after Eating is the Prominent Symptom* —I have tried the drug upon twelve cases of this nature Complete relief was given in ten, one case was partially relieved, and one completely failed to derive any benefit

Apart from its internal use, papain will probably come into extensive use as a peptonizing agent, to prepare ready digested food and enemata, in the way in which pancreatin and pepsin are used at present —*British Medical Journal*, April 3, 1886

CORROSIVE SUBLIMATE IN DIPHTHERIA — DR WERNER, medical officer to a circumscribed factory population of about 2000 near Narwa, in the Gulf of Finland, writes in the *St Petersburger medicinische Wochenschrift* describing the satisfactory results he has obtained in diphtheria by treatment with perchloride of mercury internally, combined with ichthyol inunctions The disease is very frequent and fatal in the locality, he having attended during the last six years ninety cases, the average mortality of which was between 60 and 70 per cent, the majority succumbing from general weakness when the local affection was passing off or after it had quite disappeared Last year the type was peculiarly severe In July, August, and September eleven cases occurred, of which no less than nine proved fatal From the end of September to the present time, however, during which period there have occurred seventeen cases, all of which were treated with perchloride of mercury, and many of which were very severe, there were only two fatal cases, neither of which was seen till a few hours before death The author's method is as follows For young children he dissolves a quarter of a grain of the perchloride in 4 oz of water, for children of 6 or 7 half a grain in 6 oz of water, and for adults three quarters of a grain in 8 oz of water This solution is given to the patients while they are awake every twenty or thirty minutes, in measured doses, so arranged that the quantities made up shall last from twenty to twenty-four hours—*i e*, about half a drachm in the case of young children and a drachm in that of adults When a good deal of sleep is obtained larger doses are given at longer intervals As a rule only milk is allowed as nourishment If considerable pyrexia exists, an enema of from ten to thirty grains of antipyrin, according to the age of the patient, is given, the rectum having been previously cleared out Externally ichthyol is diligently rubbed in over the swollen glands three or four times a day, the fingers being wetted with water when dry to permit of the rubbing being continued for some time For the first two days of this treatment the local affection usually undergoes no improvement, but on the third day it begins to diminish and the general condition becomes better, the appetite increasing and the children regaining their wonted spirits In no case did the author meet with the extreme debility which was frequent in cases treated by pilocarpine, even when the local affection was decreasing As the patients approach convalesence the medicine was diminished, so that more than six bottles were never required Complications never occurred, though three of the patients had previously had scarlatina —*Lancet*, April 3, 1886

CALOMEL AS A DIURETIC —JENDRASSIK has used calomel with excellent results in the dropsy of heart-disease In six cases, comprising twenty four separate experiments, diuresis occurred twenty-three times, the maximum daily amount of urine varying between 2,100 and 9,500 cubic centimètres (95 to 339 ounces) The amount of diuresis depends on the dose of calomel given As a rule, the dose was 0 2 gramme (1½ grain), three to five times a day The diuresis did not appear till after the administration of the drug for one day, and lasted as long as the œdema was present Unfavorable symptoms noticed were a metallic taste in the mouth, salivation, and stomatitis, but it is important, the author says, that the diuresis appears before the onset of diarrhœa caused by the drug The urine contains an excess of chlorides, hyaline casts are often seen In a case of pleurisy, with effusion, calomel had no effect on the urine As to the mode of action of the drug in cases of cardiac dropsy, the author says that it can hardly be through the heart, which is only secondarily and slightly affected by calomel It is probably through the kidneys, a sort of diabetes insipidus being established As precautions in the employment of this mode of treatment, small doses of laudanum combat incipient diarrhœa, and for the stomatitis a mouth-wash of chloral of potash is prescribed from the first Though no harmful action on the kidneys was noticed, a caution is given against employing this treatment in disease of the kidneys —*London Medical Record*, March 15, 1886

A Test for Sugar in the Urine —A Philadelphia correspondent of the *Atlanta Medical and Surgical Journal* states that it might be of interest to mention a convenient substitute for Fehling's solution in testing for sugar in the urine The ordinary solutions deteriorate on keeping, and are liable to throw down the sub oxide of copper themselves if not freshly prepared Prof Holland, of the Jefferson Medical College, recently gave the following test fluid, which is very efficient, is easily prepared, and is not spoiled by keeping

GLYCERINE CUPRIC SOLUTION

℞ Cupric sulphate ʒj
Glycerine fʒj

To make the test add five drops of this solution to one drachm of liquor potassæ, in a test-tube Boil a few minutes to test the purity of the fluid, should it remain clear then add a few drops of the urine If glucose be present in quantity there is at once thrown down a red precipitate, just as in the ordinary Fehling's test To detect minute amounts of sugar, not shown by above procedure, after making the test as above, add half a drachm of urine, boil and set aside If sugar be present, even in very minute quantity, the liquor, as it cools, will turn to an olive green color and become turbid —*The College and Clinical Record*, April 1, 1886

The Metallic Suture in Fracture of the Patella —At the close of a paper on this subject Dr Frederic S Dennis, of New York, draws the following conclusions

First—In compound fractures of the patella there is not the slightest question as to the propriety of the operation of wiring the fragments Fowler's cases, James's, and my own, bear undisputed testimony in corroboration of this statement

Second —In recent and old fractures, with the full permission of the patient and under the strictest antiseptic precautions, the operation, in the light of present statistics, is wholly justifiable

Third —In debilitated patients, and in those suffering from any organic disease, the operation should not be employed, and is, in fact, contra indicated, as all other operations of expediency

Fourth —It is not an operation which can be indiscriminately performed, and never by an ordinary practitioner with little surgical experience and with little faith in the germ-theory of inflammation

Fifth —The success of this operation depends wholly upon conscientiously carrying out the smallest detail in aseptic surgery, and the surgeon who is not imbued with the true spirit of antiseptic surgery is guilty of a criminal act toward humanity if he attempts this operation

Sixth —While the number of cases yet operated upon is too limited to admit of deductions by means of which a final settlement of this question can be made in the minds of surgeons, the future practice of the surgery of America, the birthplace of this operation, and the practice of other countries, will soon enable us to condemn it as an unsafe and unjustifiable procedure, or else it will raise it to a pinnacle from which we can recognize one of the grandest triumphs of our art —*New York Medical Journ* , April 10, 1886

Cholera and Neuroparalytic Keratitis —The distinguished oculist, Dr Aguilar y Blanch, contributes to the *Cronica Medica* of Valencia a paper on cholera and neuro paralytic keratitis His conclusions are these 1 Cholera may give rise to a disturbance of the visual apparatus 2 This is most apt to occur in the comatose form of the disease 3 Children, and individuals with little organic resistance, are most affected 4 The poor and ill-fed give the greatest contingent of patients 5 The ocular affection is characterised by a neuro paralytic keratitis 6 In the majority of cases, both eyes are affected 7 It follows the ordinary phases of this form, *i e* primary molecular mortification of whitish color becoming yellowish, extending superficially rather than in depth, disintegration of the elements in its centre, perforation, hernia of the iris, total mortification of the corneæ, phlegmon of the eye 8 The point affected is always the centre of the cornea, from whence it extends after previous infiltration 9 The disease yields promptly, if taken in the early stage and with appropriate treatment 10 The treatment consists in hot fomentations, bandage, eserine, iodoform, and tonics —*London Medical Record*, March 15, 1886

Treatment of Peri-uterine Hæmatocele by Means of Negative Galvano Puncture —At a recent meeting of the *Association Française pour l' Avancement des Sciences,* Apostoli described this method as follows The chemical-caustic action of the continuous current is utilized in making an opening into these tumors The opening thus made is, in character, a non-retractile fistula, with tendency to remain open, and with adhesions between the pathological cavity and the external mucous membrane The depth of the fistula varies with the intensity of the current strength The advantage of this method is that, on account of the adhesions formed, the danger of opening is lessened, and the cicatrix left by the negative eschar is slight and non contractile A further after effect of this method of utilizing the chemical caustic action of this current is that the nutrition of these pathological cavities is modified, leading to rapid retrograde metamorphosis Apostoli has treated one case by this method, and the excellent result obtained leads him to the following general conclusions The method is safe, quick in action, and modifies the usual prognosis The method is, in action, double—it has a surgical effect and a medical effect It is applicable alike to hæmatocele, abscess, fibromata, interstitial myomata, extrauterine cysts —*American Journal of Obstetrics*, April, 1886

THE PHYSICIAN AND HIS CULTURE

An English contemporary, in a recent note under this title, quotes Sir Robert Christison as an authority that Latin and Greek cannot be dispensed with in the education of one who hopes to be a successful physician, and that medical nomenclature, so largely of Greek and Latin derivation, cannot dispense with the ancient languages and rely upon Saxon words, and few, we think, will take exception to these propositions Just how well versed in the classics the physician should be, however, is a point which Sir Robert does not discuss, nor will we until something has been said regarding other matters relating to the general and special culture of professional men

Culture has been well defined as that knowledge or training which is essential to, at least, a provisional completeness of human nature, and a large part of it consists in having a due appreciation of the extent and importance of those fields or branches of knowledge which we cannot make our own, being outside of our profession or line of work Students of a learned profession who delve in outside fields acknowledge, consciously or unconsciously, the law of alternation and remission of activity Sleep, of course, is the only entire and absolute cessation of activity, and if we may believe that there can be sleep without dreaming, this is the most complete cessation During the waking hours the most complete diversion is afforded by our meals, during which, if we do not eat alone, the trains of thought are changed while the body is rested So also of bodily and muscular exercise, and Mr Gladstone's *penchant* for wood chopping, so far from being a vagary or denoting eccentricity, is simply the wise recognition and following out of a physiological law But aside from this, What is gained by alternation of activities, by dropping one form of mental work and taking up another? The first consideration is that in order to derive benefit from it the first form of activity must not have produced exhaustion, and exhaustion is shown when, on taking up a new form of activity, the mind continues to run in the old channels The taking up of another form of activity may be really a remission of intellectual strain It is not necessary to be idle to rest the brain, on the contrary, it is generally better to take up an amusing and lighter occupation than to be entirely idle The "rest, that strengthens unto virtuous deeds" is, then, not the rest of idlenesss, a fact recognized by Cowper when he says

> "Absence of occupation is not rest
> A mind quite vacant is a mind distress'd"

Obviously, our word culture may relate either to something acquired by the youth before entering upon the study and practice of his profession, or to some subject in which the practising physician becomes interested and learned or skilled—and we may very properly designate these as involuntary and voluntary culture Of these the latter is usually more complete, and generally, though not necessarily, more useful When acquired by professional men it is usually gained while in pursuit of mental relaxation, which is so necessary to those who do faithful work in their chosen fields "Do you imagine," says Cicero, "that I could bear up against such a strain if I did not relieve it (the mind) occasionally by philosophical inquiries?" The actions, if not the words, of learned men of almost all ages have borne out this idea We see the Premier of a great nation turning aside temporarily from the cares of State to write forcibly and learnedly of philosophical and historical matters A surgeon lays away the scalpel to investigate principles of combustion Egorovitch Min takes refuge from professional cares in language studies and leaves the literature of his country in debt to him when he dies It is easily seen that these are not isolated cases, on the contrary, it seems to be the rule with the most diligent workers in any department to have some outside study for the relaxation, conscious or unconscious, and amusement which it gives It is not the indulgence of idleness, for men who work cannot enjoy absolute inactivity, nor can they be inactive We may paraphrase the saying of Euripides, "there is no one who seeks to live in pleasure that has reached fame," by "there is no one who reaches fame that can live in pleasure, man must labor," if by pleasure he meant inactivity, idleness or ease

That no absolute rule can be laid down for all men mode of treatment, small doses of laudanum combat incipient diarrhœa, and for the stomatitis a mouth-wash of chloral of potash is prescribed from the first. Though no harmful action on the kidneys was noticed, a caution is given against employing this treatment in disease of the kidneys.—*London Medical Record*, March 15, 1886.

A Test for Sugar in the Urine.—A Philadelphia correspondent of the *Atlanta Medical and Surgical Journal* states that it might be of interest to mention a convenient substitute for Fehling's solution in testing for sugar in the urine. The ordinary solutions deteriorate on keeping, and are liable to throw down the sub-oxide of copper themselves if not freshly prepared. Prof. Holland, of the Jefferson Medical College, recently gave the following test fluid, which is very efficient, is easily prepared, and is not spoiled by keeping:

GLYCERINE CUPRIC SOLUTION.

℞ Cupric sulphate ʒj
Glycerine fʒj

To make the test add five drops of this solution to one drachm of liquor potassæ, in a test-tube. Boil a few minutes to test the purity of the fluid; should it remain clear then add a few drops of the urine. If glucose be present in quantity there is at once thrown down a red precipitate, just as in the ordinary Fehling's test. To detect minute amounts of sugar, not shown by above procedure, after making the test as above, add half a drachm of urine, boil and set aside. If sugar be present, even in very minute quantity, the liquor, as it cools, will turn to an olive green color and become turbid.—*The College and Clinical Record*, April 1, 1886.

The Metallic Suture in Fracture of the Patella.—At the close of a paper on this subject Dr. Frederic S. Dennis, of New York, draws the following conclusions:

First.—In compound fractures of the patella there is not the slightest question as to the propriety of the operation of wiring the fragments. Fowler's cases, James's, and my own, bear undisputed testimony in corroboration of this statement.

Second.—In recent and old fractures, with the full permission of the patient and under the strictest antiseptic precautions, the operation, in the light of present statistics, is wholly justifiable.

Third.—In debilitated patients, and in those suffering from any organic disease, the operation should not be employed, and is, in fact, contra-indicated, as all other operations of expediency.

Fourth.—It is not an operation which can be indiscriminately performed, and never by an ordinary practitioner with little surgical experience and with little faith in the germ-theory of inflammation.

Fifth.—The success of this operation depends wholly upon conscientiously carrying out the smallest detail in aseptic surgery, and the surgeon who is not imbued with the true spirit of antiseptic surgery is guilty of a criminal act toward humanity if he attempts this operation.

Sixth.—While the number of cases yet operated upon is too limited to admit of deductions by means of which a final settlement of this question can be made in the minds of surgeons, the future practice of the surgery of America, the birthplace of this operation, and the practice of other countries, will soon enable us to condemn it as an unsafe and unjustifiable procedure, or else it will raise it to a pinnacle from which we can recognize one of the grandest triumphs of our art.—*New York Medical Jour.*, April 10, 1886.

Cholera and Neuroparalytic Keratitis.—The distinguished oculist, Dr. Aguilar y Blanch, contributes to the *Cronica Medica* of Valencia a paper on cholera and neuro-paralytic keratitis. His conclusions are these: 1. Cholera may give rise to a disturbance of the visual apparatus. 2. This is most apt to occur in the comatose form of the disease. 3. Children, and individuals with little organic resistance, are most affected. 4. The poor and ill-fed give the greatest contingent of patients. 5. The ocular affection is characterised by a neuro-paralytic keratitis. 6. In the majority of cases, both eyes are affected. 7. It follows the ordinary phases of this form, *i. e.* primary molecular mortification of whitish color becoming yellowish, extending superficially rather than in depth, disintegration of the elements in its centre, perforation, hernia of the iris, total mortification of the corneæ, phlegmon of the eye. 8. The point affected is always the centre of the cornea, from whence it extends after previous infiltration. 9. The disease yields promptly, if taken in the early stage and with appropriate treatment. 10. The treatment consists in hot fomentations, bandage, eserine, iodoform, and tonics.—*London Medical Record*, March 15, 1886.

Treatment of Peri-uterine Hæmatocele by Means of Negative Galvano-Puncture.—At a recent meeting of the *Association Française pour l' Avancement des Sciences*, Apostoli described this method as follows: The chemical caustic action of the continuous current is utilized in making an opening into these tumors. The opening thus made is, in character, a non-retractile fistula, with tendency to remain open, and with adhesions between the pathological cavity and the external mucous membrane. The depth of the fistula varies with the intensity of the current strength. The advantage of this method is that, on account of the adhesions formed, the danger of opening is lessened, and the cicatrix left by the negative eschar is slight and non-contractile. A further after-effect of this method of utilizing the chemical caustic action of this current is that the nutrition of these pathological cavities is modified, leading to rapid retrograde metamorphosis. Apostoli has treated one case by this method, and the excellent result obtained leads him to the following general conclusions: The method is safe, quick in action, and modifies the usual prognosis. The method is, in action, double—it has a surgical effect and a medical effect. It is applicable alike to hæmatocele, abscess, fibromata, interstitial myomata, extrauterine cysts.—*American Journal of Obstetrics*, April, 1886.

THE PHYSICIAN AND HIS CULTURE

An English contemporary, in a recent note under this title, quotes Sir Robert Christison as an authority that Latin and Greek cannot be dispensed with in the education of one who hopes to be a successful physician, and that medical nomenclature, so largely of Greek and Latin derivation, cannot dispense with the ancient languages and rely upon Saxon words, and few, we think, will take exception to these propositions Just how well versed in the classics the physician should be, however, is a point which Sir Robert does not discuss, nor will we until something has been said regarding other matters relating to the general and special culture of professional men

Culture has been well defined as that knowledge or training which is essential to, at least, a provisional completeness of human nature, and a large part of it consists in having a due appreciation of the extent and importance of those fields or branches of knowledge which we cannot make our own, being outside of our profession or line of work Students of a learned profession who delve in outside fields acknowledge, consciously or unconsciously, the law of alternation and remission of activity Sleep, of course, is the only entire and absolute cessation of activity, and if we may believe that there can be sleep without dreaming, this is the most complete cessation During the waking hours the most complete diversion is afforded by our meals, during which, if we do not eat alone, the trains of thought are changed while the body is rested So also of bodily and muscular exercise, and Mr Gladstone's *penchant* for wood-chopping, so far from being a vagary or denoting eccentricity, is simply the wise recognition and following out of a physiological law But aside from this, What is gained by alternation of activities, by dropping one form of mental work and taking up another? The first consideration is that in order to derive benefit from it the first form of activity must not have produced exhaustion, and exhaustion is shown when, on taking up a new form of activity, the mind continues to run in the old channels The taking up of another form of activity may be really a remission of intellectual strain It is not necessary to be idle to rest the brain, on the contrary, it is generally better to take up an amusing and lighter occupation than to be entirely idle The "rest, that strengthens unto virtuous deeds" is, then, not the rest of idlenesss, a fact recognized by Cowper when he says

> "Absence of occupation is not rest
> A mind quite vacant is a mind distress'd."

Obviously, our word culture may relate either to something acquired by the youth before entering upon the study and practice of his profession, or to some subject in which the practising physician becomes interested and learned or skilled—and we may very properly designate these as involuntary and voluntary culture Of these the latter is usually more complete, and generally, though not necessarily, more useful When acquired by professional men it is usually gained while in pursuit of mental relaxation, which is so necessary to those who do faithful work in their chosen fields "Do you imagine," says Cicero, "that I could bear up against such a strain if I did not relieve it (the mind) occasionally by philosophical inquiries?" The actions, if not the words, of learned men of almost all ages have borne out this idea We see the Premier of a great nation turning aside temporarily from the cares of State to write forcibly and learnedly of philosophical and historical matters A surgeon lays away the scalpel to investigate principles of combustion Egorovitch Min takes refuge from professional cares in language studies and leaves the literature of his country in debt to him when he dies It is easily seen that these are not isolated cases, on the contrary, it seems to be the rule with the most diligent workers in any department to have some outside study for the relaxation, conscious or unconscious, and amusement which it gives It is not the indulgence of idleness, for men who work cannot enjoy absolute inactivity, nor can they be inactive We may paraphrase the saying of Euripides, "there is no one who seeks to live in pleasure that has reached fame," by "there is no one who reaches fame that can live in pleasure, man must labor," if by pleasure he meant inactivity, idleness or ease

That no absolute rule can be laid down for all men as regards the different side studies by which the mind may be relaxed, rested, and at the same time fertilized, goes without saying The most that can be said may be given in Bain's words "The kind of change that may take place within the field of study itself, and that may operate both as a relief from strain and as a reclamation of waste ground, is best exemplified in such matters as these —In the act of learning generally there is a two fold attitude—observing what is to be done, and doing it In verbal exercises we first listen and then repeat, in handicraft, we look at the model, and then reproduce it Now the proportioning of the two attitudes is a matter of economical adjustment" Too much observing impairs the energy for action Working from a model gives the proper adjustment between observing and doing One of the most marked contrasts, and a most grateful change, is the passing from the study of science to that of language The transition from one department of science to another is often a most grateful relaxation The change from one language to another is a real, though not a very marked relief, save when it is made from the less to the better known The study of the fine arts brings distinctive organs into use, and has to many a pleasurable interest not usually possessed by other studies Many of the "outside studies" have a very direct bearing on medicine modern languages, biology, zoology, physiological chemistry, drawing and modeling may be mentioned as the more important in this connection When properly undertaken these studies constitute something more than mere amusement, as indeed may be said of any side study Very valuable work has been done during excursions into other fields than the chosen profession, as witness the work of James Veitch, the plow-maker, in optics, and, we may add, his discovery of David Brewster, who, in turn, did most excellent philosophical work while yet a minister The same is true of Priestley In these two cases, however, the side study took "the expulsive power of a new affection"

The study of foreign languages is of great importance to the physician, even though he may have no taste for general literature In very many cases there is no necessity for a teacher, and time and opportunity may be wanting to attend a regular class By subscribing for a medical journal and buying a grammar and dictionary of the language to be studied, one may by a little earnest work each day soon acquire sufficient familiarity with the language to read it readily Some have questioned the value of biology to medical men—the logical connection between the purely scientific doctrine of disease and biology The answer given by Mr Huxley is sufficiently clear "Living matter is characterized by its innate tendency to exhibit a definite series of the morphological and physiological phenomena which constitute organization and life Given a certain range of conditions, and these phenomena remain the same, within narrow limits, for each kind of living thing They furnish the normal and typical character of the species, and as such, they are the subject matter of ordinary biology pathology is a branch of biology, it is the morphology, the physiology, the distribution, the ætiology of abnormal life"

The practical study of physiological chemistry, while not a purely side study, may also be mentioned Very valuable work in this field has been done by physicians in active practice Of the study of the fine arts, including modeling, it may be said that they not only possess a rare interest, but a knowledge of drawing and modeling is of very great practical value to the doctor They are much more cultivated abroad than in America We cannot expect that every doctor may become an artist or a sculptor, but there are very few who cannot learn to draw a good figure, or to make a fair model of a diseased or malformed part A practical knowledge of mechanics is also of value Mechanical and physical principles are constantly coming up in medicine It is not necessary that the doctor should be able to make a steam engine, but so much the better if he can This knowledge is especially valuable to the surgeon, and to that man of (usually) so many resources, the country doctor

We have already signified our agreement with Sir Robert Christison, and the *Lancet*, that the Greek and Latin derivatives cannot be superseded in medical nomenclature The truth of this is apparent on a very superficial examination, though not because some one says it in an autobiography Ichthyosis is in every way preferable to any Saxon name that can be used for it This, however, would not justify the assertion that one who is even a master of the Greek language would know, by the etymology alone, what ichthyosis is or means The chief merit of this nomenclature is that it may be used by writers in all languages, whereas if we had a Saxon term, the German writers would have a German term, the French a French term, and so on to the end of the chapter The fact is, too much of this is now done, especially by foreign writers Our French and Italian *confrères*, especially, seem to have a special aversion to the use of scientific terms But as regards Sir Robert Christison's saying of Latin and Greek, "*that of all the studies suitable* for boyhood there is no other which is so likely to strengthen the memory, imagination, attention, and judgment, so certain to instil taste, so useful for imperceptibly infusing an accurate and ready use of English, or so indispensable as the groundwork for acquiring modern tongues," it is only necessary to say that it shows a want of knowledge of the mental processes involved in studying any subject, and, further, of the family relationships of some of the modern languages It is a mistake to attempt to prove something by quoting what some one says of it

THE PAPERS AND THE DISCUSSIONS ON PAPERS READ BEFORE THE ASSOCIATION

In view of the facts that the discussions on papers read before societies are often as valuable as the papers, and that those who engage in the discussions frequently complain of the manner in which their remarks are reported, it seems desirable that each one discussing a paper should write out his intended remarks previous to the reading of the paper, and amend them afterwards if necessary, or else should write them out in full as soon after the discussion as possible When possible the remarks should be written out in ink, the pages properly numbered, with the *name* of the reader of the paper, the *title* of the paper, and the *name* and *address* of the speaker on the first page

It would seem unnecessary to call attention to the fact that the reader of a paper should put his *name* and *address* on the paper, with the date on which it is read, and whether read by title or in a Section One or more papers read at the last annual meeting of the Association were sent to THE JOURNAL with no clue whatever as to the author When papers are written in parts, each part should be distinctly marked Neglect of this precaution last year caused a valuable paper to be printed second part first, since there was nothing, in the subject matter of the parts, which indicated which should have precedence Each illustration for a paper should have the name of the author upon it, and each one should be numbered If one author have more than one illustrated paper, a part of the title of the paper to which it belongs should be also placed on the illustration

We would again remind members of the Association that all addresses, papers, and discussions are the exclusive property of the Association, and should be delivered to the Permanent Secretary or to the Secretary of the Section in which they are read during the meeting of the Association The rule on this subject is explicit, and having been adopted by the Association is binding upon each member

A NEW TEST OF MEDICAL COLLEGE STANDING

The Illinois State Board of Health held its regular quarterly meeting in Chicago, commencing April 15, 1886 From a brief report of its doings in the *Chicago Herald* of the 16th we clip the following "Those present were Drs Bateman, Clark, Ludlam, Rauch and MacKenzie A resolution was passed to the effect that the continuous graduation of 45 per cent of the total number of matriculates of a medical college—due allowance being made for the average annual loss—must be accepted as *prima facie* evidence that practically every candidate is graduated without regard to competency or qualification, that it be resolved that no medical college be recognized as in good standing within the meaning and intent of the act to regulate the practice of medicine in the State of Illinois, the aggregate graduates of which amount to 45 per cent of its aggregate matriculates during a period of five years ending with any session subsequent to the session of 1885–86"

From this it appears that any person who hereafter presents a diploma to the Illinois State Board of Health to procure a license to practice in that State, must accompany it with proof that the college granting the diploma had not during the five years preceding the date of said diploma graduated an average of 45 per cent of the whole number of its matriculates Or will the Illinois State Board of Health add to the list of requirements that all medical colleges must comply with in order to be recognized as in "good standing," another, requiring the Dean or Secretary of every medical college in this country to furnish the Secretary of the Board, annually, a sworn statement of the actual matriculates and graduates under penalty of forfeiting the "good standing" of the college if he refuses or omits to comply? Only a few months since, Judge McAllister, in rendering a decision of the Appellate Court in this city, declared very distinctly that the Illinois State Board of Health was an executive body simply, with no legislative functions, more especially in regard to medical colleges But nevertheless, the Board continues to perform the double duty of both making and executing laws This last act of legislation may be found rather difficult of execution It may be found quite as easy for a medical college to add to the published list of its classes enough names to keep the list of their graduates from exceeding 44 per cent, as it is for it to insert a clause in its announcements saying that a certain amount of general education will be required for admission whether any attention is ever given to its execution or not as regards the different side studies by which the mind may be relaxed, rested, and at the same time fertilized, goes without saying. The most that can be said may be given in Bain's words: "The kind of change that may take place within the field of study itself, and that may operate both as a relief from strain and as a reclamation of waste ground, is best exemplified in such matters as these:—In the act of learning generally there is a two fold attitude—observing what is to be done, and doing it. In verbal exercises we first listen and then repeat; in handicraft, we look at the model, and then reproduce it. Now the proportioning of the two attitudes is a matter of economical adjustment." Too much observing impairs the energy for action. Working from a model gives the proper adjustment between observing and doing. One of the most marked contrasts, and a most grateful change, is the passing from the study of science to that of language. The transition from one department of science to another is often a most grateful relaxation. The change from one language to another is a real, though not a very marked relief, save when it is made from the less to the better known. The study of the fine arts brings distinctive organs into use, and has to many a pleasurable interest not usually possessed by other studies. Many of the "outside studies" have a very direct bearing on medicine: modern languages, biology, zoology, physiological chemistry, drawing and modeling may be mentioned as the more important in this connection. When properly undertaken these studies constitute something more than mere amusement, as indeed may be said of any side study. Very valuable work has been done during excursions into other fields than the chosen profession, as witness the work of James Veitch, the plow-maker, in optics; and, we may add, his discovery of David Brewster, who, in turn, did most excellent philosophical work while yet a minister. The same is true of Priestley. In these two cases, however, the side study took "the expulsive power of a new affection."

The study of foreign languages is of great importance to the physician, even though he may have no taste for general literature. In very many cases there is no necessity for a teacher, and time and opportunity may be wanting to attend a regular class. By subscribing for a medical journal and buying a grammar and dictionary of the language to be studied, one may by a little earnest work each day soon acquire sufficient familiarity with the language to read it readily. Some have questioned the value of biology to medical men—the logical connection between the purely scientific doctrine of disease and biology. The answer given by Mr. Huxley is sufficiently clear: "Living matter is characterized by its innate tendency to exhibit a definite series of the morphological and physiological phenomena which constitute organization and life. Given a certain range of conditions, and these phenomena remain the same, within narrow limits, for each kind of living thing. They furnish the normal and typical character of the species, and as such, they are the subject matter of ordinary biology pathology is a branch of biology; it is the morphology, the physiology, the distribution, the ætiology of abnormal life."

The practical study of physiological chemistry, while not a purely side study, may also be mentioned. Very valuable work in this field has been done by physicians in active practice. Of the study of the fine arts, including modeling, it may be said that they not only possess a rare interest, but a knowledge of drawing and modeling is of very great practical value to the doctor. They are much more cultivated abroad than in America. We cannot expect that every doctor may become an artist or a sculptor, but there are very few who cannot learn to draw a good figure, or to make a fair model of a diseased or malformed part. A practical knowledge of mechanics is also of value. Mechanical and physical principles are constantly coming up in medicine. It is not necessary that the doctor should be able to make a steam engine, but so much the better if he can. This knowledge is especially valuable to the surgeon, and to that man of (usually) so many resources, the country doctor.

We have already signified our agreement with Sir Robert Christison, and the *Lancet*, that the Greek and Latin derivatives cannot be superseded in medical nomenclature. The truth of this is apparent on a very superficial examination, though not because some one says it in an autobiography. Ichthyosis is in every way preferable to any Saxon name that can be used for it. This, however, would not justify the assertion that one who is even a master of the Greek language would know, by the etymology alone, what ichthyosis is or means. The chief merit of this nomenclature is that it may be used by writers in all languages; whereas if we had a Saxon term, the German writers would have a German term, the French a French term, and so on to the end of the chapter. The fact is, too much of this is now done, especially by foreign writers. Our French and Italian *confrères*, especially, seem to have a special aversion to the use of scientific terms. But as regards Sir Robert Christison's saying of Latin and Greek, "that of all the studies suitable for boyhood there is no other which is so likely to strengthen the memory, imagination, attention, and judgment, so certain to instil taste, so useful for imperceptibly infusing an accurate and ready use of English, or so indispensable as the groundwork for acquiring modern tongues," it is only necessary to say that it shows a want of knowledge of the mental processes involved in studying any subject, and, further, of the family relationships of some of the modern languages It is a mistake to attempt to prove something by quoting what some one says of it

THE PAPERS AND THE DISCUSSIONS ON PAPERS READ BEFORE THE ASSOCIATION

In view of the facts that the discussions on papers read before societies are often as valuable as the papers, and that those who engage in the discussions frequently complain of the manner in which their remarks are reported, it seems desirable that each one discussing a paper should write out his intended remarks previous to the reading of the paper, and amend them afterwards if necessary, or else should write them out in full as soon after the discussion as possible When possible the remarks should be written out in ink, the pages properly numbered, with the *name* of the reader of the paper, the *title* of the paper, and the *name* and *address* of the speaker on the first page

It would seem unnecessary to call attention to the fact that the reader of a paper should put his *name* and *address* on the paper, with the date on which it is read, and whether read by title or in a Section One or more papers read at the last annual meeting of the Association were sent to THE JOURNAL with no clue whatever as to the author When papers are written in parts, each part should be distinctly marked Neglect of this precaution last year caused a valuable paper to be printed second part first, since there was nothing, in the subject matter of the parts, which indicated which should have precedence Each illustration for a paper should have the name of the author upon it, and each one should be numbered If one author have more than one illustrated paper, a part of the title of the paper to which it belongs should be also placed on the illustration

We would again remind members of the Association that all addresses, papers, and discussions are the exclusive property of the Association, and should be delivered to the Permanent Secretary or to the Secretary of the Section in which they are read during the meeting of the Association The rule on this subject is explicit, and having been adopted by the Association is binding upon each member

A NEW TEST OF MEDICAL COLLEGE STANDING

The Illinois State Board of Health held its regular quarterly meeting in Chicago, commencing April 15, 1886 From a brief report of its doings in the *Chicago Herald* of the 16th we clip the following "Those present were Drs Bateman, Clark, Ludlam, Rauch and MacKenzie A resolution was passed to the effect that the continuous graduation of 45 per cent of the total number of matriculates of a medical college—due allowance being made for the average annual loss—must be accepted as *prima facie* evidence that practically every candidate is graduated without regard to competency or qualification, that it be resolved that no medical college be recognized as in good standing within the meaning and intent of the act to regulate the practice of medicine in the State of Illinois, the aggregate graduates of which amount to 45 per cent of its aggregate matriculates during a period of five years ending with any session subsequent to the session of 1885–86"

From this it appears that any person who hereafter presents a diploma to the Illinois State Board of Health to procure a license to practice in that State, must accompany it with proof that the college granting the diploma had not during the five years preceding the date of said diploma graduated an average of 45 per cent of the whole number of its matriculates Or will the Illinois State Board of Health add to the list of requirements that all medical colleges must comply with in order to be recognized as in "good standing," another, requiring the Dean or Secretary of every medical college in this country to furnish the Secretary of the Board, annually, a sworn statement of the actual matriculates and graduates under penalty of forfeiting the "good standing" of the college if he refuses or omits to comply? Only a few months since, Judge McAllister, in rendering a decision of the Appellate Court in this city, declared very distinctly that the Illinois State Board of Health was an executive body simply, with no legislative functions, more especially in regard to medical colleges But nevertheless, the Board continues to perform the double duty of both making and executing laws This last act of legislation may be found rather difficult of execution It may be found quite as easy for a medical college to add to the published list of its classes enough names to keep the list of their graduates from exceeding 44 per cent, as it is for it to insert a clause in its announcements saying that a certain amount of general education will be required for admission whether any attention is ever given to its execution or not

STROPHANTHUS

The physicians in this country who have made unsuccessful attempts to obtain specimens of this drug will be pleased to learn that a tincture, prepared by the method and of the strength recommended by Professor Fraser, is now made by MM Burroughs and Welcome, Snow Hill Buildings, London, E C The *British Medical Journal* describes it as a clear, dark amber-colored fluid, miscible with water in all proportions, and yielding an opalescent solution It can be dispensed with acids or alkalies, and does not change color with perchloride of iron Its chief drawback is its intensely bitter taste, but it is seen that it has pharmacopœial advantages over tincture of digitalis

Epidemic Cholera —As the warm season advances in the south of Europe, indications of the spread of cholera are again attracting attention A despatch dated Paris, April 16, states that sixty-eight cases had occurred in Brindisi, Italy, and that sixteen deaths had taken place between the 8th and the 16th inst It is reported that very stringent precautions are being taken to prevent its crossing the frontiers of both France and Austria Still, the officials of Brindisi claim that the disease is sporadic

SOCIETY PROCEEDINGS.

GYNÆCOLOGICAL SOCIETY OF BOSTON

Stated Meeting, March 11, 1886

The President, Henry O Marcy, M D,
in the Chair
H J Harriman, M D, Secretary

The records of the February meeting were read and approved

Dr R J P Goodwin, of East Boston, and Dr W Thornton Parker, of Newport, R I, were

elected to active membership

Dr H M Field then presented a report of

A CASE OF INVERSION OF THE UTERUS, FOLLOWING UPON PARTURITION

Mrs J W B, 25 years of age, was confined with her first child on February 7, with a tedious and rather severe labor of twenty-eight hours Delay had been chiefly caused by a rigid os Fifteen hours before the birth a two gallon douche of hot water was administered, but had no effect Dr Field could remember but one previous instance in which this measure had failed to hasten dilatation of the os No anæsthetics were used An attempt to administer chloral hydrate by mouth and rectum was unsuccessful An occasional suppository of morphine and belladonna worked admirably Thenceforth for nine hours progress was slow, the diameter of the uterine orifice being but little increased A second hot douche was administered, and the hard, cartilaginous ring of the os at once began to relax, and the labor proceeded steadily until the birth of the child, three hours afterwards

At once, upon extrusion of the head, ʒij of fluid extract of ergot were administered The fundus uteri was followed down by the left hand and, immediately after the birth of the child, Credé's method of expelling the placenta was applied, cautious and tentative traction being at the same time made upon the cord Almost at once the patient uttered some exclamation, and it was discovered that both uterus and placenta were in the bed, the one organ so adherent to the other that it was difficult to determine the line of division The placenta having been removed the uterus was reposited without much effort by steady and increasing pressure of the four fingers upon the fundus, the thumb lying upon the palm The hand was retained *in utero* for a little while to ensure continued contraction, and also to ascertain if any shreds of placental tissue still remained in the cavity On turning the attention to the patient it was discovered that the abdomen was so distended with gas that it was difficult to feel the womb in its cavity The change in facial expression was sudden and very marked The young and beautiful face which just before had been full of blood suddenly became pinched and haggard, and the color a bluish-white Although everything proceeded favorably in the future progress of the case, it required nearly a week for a look thus suddenly assumed to pass entirely away This, doubtless, represented shock No hæmorrhage occurred, and the patient recovered without any untoward symptoms

Dr Henry E Crampton, of New York, in an ad admirable monograph upon "Inversion of the Uterus, following upon Parturition," published in the *American Journal of Obstetrics*, has given the literature of the subject The present case well illustrates the following remark "Shock is rarely absent There is a peculiar anxious expression and manner Every movement shows how profoundly the whole nervous system sympathizes with the terrible dislocation" In regard to traction upon the cords as a cause of inversion, Dr Crampton says "Traction upon the cord may produce prolapsus, if severe, procedentia It will never alone produce inversion, but may facilitate it if paresis is present" It is most apt to occur in first deliveries, and is referable to a degree of paralysis in the uterine muscle, brought about by a tedious and exhausting labor Death ensues in about twenty per cent of recent cases, whatever the treatment A visit to Mrs B four weeks after delivery found her well No irregularity in function of either uterus or bladder Uterus in its normal position

Dr Field closed with some remarks upon the parturient use of chloral hydrate His experience has lead him to entertain a very favorable opinion of the drug, *i e*, so far as he has been able to secure the results which belong to the remedy He called attention to an unfavorable opinion of the drug expressed by Dr A Pinard, of Paris, who has abandoned it on account of the difficulty in procuring its retention and absorption This difficulty, he insists is equally great whether exhibited by mouth or rectum If given by mouth the bulky and irritating potions, several times repeated, are apt to induce vomiting and thereby unfit the stomach for food, stimulants or medicine If given by rectum there is still greater liability that it will be discharged before it can be absorbed

Dr Field also reported a

CASE OF PROFUSE ANTE-PARTUM HÆMORRHAGE, PARTURITION, DEATH

Mrs J H L, 28 years of age, was confined at full term on January 27 She had had three previous confinements Oldest child 8 years old, youngest, 18 months No previous complication in parturition except a case of hour-glass contraction at birth of first child Mrs L was of strong physique, cheerful disposition, and had had every alleviation which money could provide Her last conception occurred while she was still nursing During later months of gestation she had been under observation on account of slight bloating and a trace of albumen in the urine

On February 27 Dr Field was summoned in haste and found patient lying in bed, very pale and evidently much frightened The pupil was so dilated that her blue eyes looked black She had had no pain, but an uneasy sensation called her to the water closet, when "something seemed to break inside," and a deluge of blood came away There were no stains on the bed and no clots in the vagina There was a slight and inconsiderable trickling of blood from the vulva She had never seen a drop of blood until the sudden flooding No parturient pain was present A gr ss suppository of morphine and a little iced brandy reassured her, the pupil returned to its normal size, and the pulse regained a fair degree of steadiness and force Digital examination revealed an os dilated to the size of a quarter of a dollar, and the fœtal head high up As the patient was not losing blood she was given a half hour's rest, material in the meantime being prepared for a tampon, should one be necessary The working hypothesis at this time was that there existed a slight lateral cervical insertion of the placenta In support of this it seemed to the examining finger as if a limited portion of the uterus just within the os felt a little thicker than neighboring parts, as if at this point the placenta might dip forward It was decided to apply a tampon to prevent any possible recurrence of the dangerous flooding Each pledget of cotton was dipped in undiluted Monsell's solution, and after being slightly oiled with cosmoline, was firmly packed in place After the vagina had been firmly packed a bandage was applied to hold the tampon in place At this time Dr Stoddard, of Newtonville, saw the patient in consultation, and approved of the treatment in every particular

After the tampon was applied ergot was given in frequent small doses, and soon labor pains set in The tampon did not prevent a slight oozing of blood, but the amount lost from the time when Dr Field first saw the case until he left the house was inconsiderable Soon the tampon began to bulge with each pain, and a watery, grumous fluid to escape The tampon was then removed, and the head was found to be engaged The labor progressed rapidly and was terminated at 5 05 P M Ergot was used both by mouth and hypodermically, and the uterus contracted at once The placenta, together with a large venous looking clot, was at once expelled, and everything seemed to be looking well Leaving a trusty nurse in charge of the uterus, half an hour was spent in fruitless efforts to resuscitate the fœtus One hour after the birth of the child it became evident that the mother was losing ground, though the uterus was well contracted and no blood of any amount being lost Resort was had to hypodermic brandy at frequent intervals At first a slight response was noticed, but later there was no response whatever, and the lamentable case terminated by the death of the mother two hours and a half after the birth of the child

It has been suggested that another method might have been adopted in the treatment of the case Turning might have been done at once when Dr Field was called to the patient Had it been a case of central implantation of the placenta, or had the flooding still continued, such heroic treatment might have been indicated, but as the hæmorrhage was under complete control and there was no indication for speedy and forcible delivery, it was thought best to give the patient a chance to rally She did rally to a good degree, and her labor was light and completed with little effort

Dr Field was disposed to believe that he underestimated the amount of blood the patient lost before he saw her Again, an autopsy might have revealed some lesion or complication which could not have been disclosed otherwise No autopsy was permitted During the last hours of life, when the patient seemed to be sinking, Dr Field explored the interior of the uterus The organ was firmly contracted, but of rather abnormal size This undue size was referable to the posterior wall of the organ, and it is possible that an autopsy might have revealed a disseminated interstitial fibroid tumor in that location

Dr Wm G Wheeler had had three cases of inversion of the uterus, and all recovered Shock is generally prominent, but is not due to loss of blood The uterus is readily replaced, but the pinched and haggard expression of the countenance is very marked, and does not disappear for several days He thought that death in Dr Field's second case might have been due to shock If this was not the case there may have been some pathological condition of the uterus which produced this unfortunate result Dr Wheeler did not think that turning would have been advisable in this case

Dr Stoddard, who was the consultant in the second case, said that he did not see the patient until after the tampon was applied, and therefore did not have the advantage of an examination of the genital tract Turning and rapid delivery was pro posed at his first visit to the patient, but as hæmorrhage was under complete control, and there was no marked indication for such heroic treatment, it was not done He regarded the treatment of the case as judicious He had never seen a case of inversion of the uterus

Dr H C White had never seen a case of inversion of the uterus He thought that shock or some unknown factor must have been the cause of death in Dr Field's second case

Dr W Symington Brown had never seen a case of inversion He did not think the second case described one of partial placenta prævia, but regarded it as more probable that it was a case of interstitial fibroid tumor Monsell's solution is not, in his opinion, a suitable styptic for use where it is necessary to tampon the vagina, as it formed a hard, leathery clot He generally uses boiling water, applied to the bleeding vessels by means of a dressing forceps and a sponge When a styptic is required on a tampon Dr, Brown uses a weak solution of tincture of iodine, and has had good results from such use It is important to combine nutrient materials, such as milk and beef tea, with stimulants where the latter remedies are required, in order that the strength of the patient may be maintained

Dr W Thornton Parker, of Newport, R I, had been much interested in the cases reported He raised the question whether death in the second case was not due to blood clot

Dr C W Stevens thought that transfusion was indicated in the second case when it was evident that the patient was sinking His experience had led him to believe that when the system was suffering from shock, absorption, either by mouth or subcutaneous tissue, was in abeyance, and that the only hope lay in throwing directly into the circulation some material suitable to support the powers of life

Dr A L Norris had seen but one case of partial inversion of the uterus In the second case reported he thought there must have been some unknown factor in producing death, such as interstitial fibroids He regarded the treatment of the case as entirely correct, and did not think that turning was admissible

Dr N O B Wingate had seen no cases of inversion He thought that internal hæmorrhage may have been the cause of death in Dr Field's second case He related a case of sudden death soon after delivery which occurred in his own practice His patient was a large and strong woman, and had been in labor twelve hours She suddenly began to sink, and delivery was hastened by using the forceps, no anæsthetics being used A child weighing 17½ lbs was delivered without very much difficulty The mother rallied well, and everything seemed to be progressing finely After reaching home he was hurriedly called again and found his patient dead The nurse reported that she gasped a few times and died very suddenly Dr Wingate thought death in this case due to heart clot

Dr Harbird asked Dr Field in regard to the amount of ergot given in his second case before the birth of the head He thought that there might have existed a rupture of the uterus which escaped notice but caused death He doubted if the loss of blood caused death, as in many cases it is known that the loss of blood may be very great and yet not destroy life

Dr L W Cushing asked if much hæmorrhage followed peeling off the placenta in the case of inversion A discussion had recently arisen in a medical society as to whether it was best to try to separate the placenta from the uterus while it was extruded, or to replace the uterus and then remove the placenta, the theory being that serious hæmorrhage would follow its removal when the uterus was inverted Dr Cushing said that transfusion was likely to be a disappointing measure in such cases as Dr Field's second case It was no easy operation to perform, and even if successfully accomplished did not often succeed in averting a fatal issue He mentioned the case of a strong and robust man in which transfusion was tried for excessive hæmorrhage from the temporal artery Although the case was a favorable one and the operation was successfully performed, the patient sank and died Dr Cushing thought there was a cause of death in such cases which might be overlooked, *i e*, the gradual formation of a clot in the venous system, beginning at the periphery, and gradually increasing until it interferes with the action of the heart or lungs Œdema of the lungs may be due to this cause

Dr Whitcomb asked if chloral hydrate could be used hypodermically He also raised the question if an idiosyncrasy to ergot did not exist in Dr Field's second case

In reply to queries made by different members during the discussion, Dr Field made the following statements Milk or other nutrient material had not been combined with the brandy on account of constant nausea He did not think that death could have been due to heart clot, as there were no symptoms present which could support such an hypothesis He was of the opinion that transfusion was indicated, and would have tried that means had he had the time and necessary apparatus The amount of ergot given in the second case before the birth of the head was about ʒj in divided doses He knew no evidence to prove that such doses of ergot ever produced toxic effects He did not think that an idiosyncrasy to ergot existed in the case Chloral hydrate could not be administered hypodermically on account of its irritating qualities No hæmorrhage of importance followed peeling off the placenta in the case of inversion

Dr Marcy, in commenting upon Dr Field's case, suggested a method of intravenous injection which he had used quite a number of times with ease and success, and which had never been reported It was the result of many experiments in injection of animals for anatomical purposes under continuous atmospheric pressure Milk is drawn directly from the animal through antiseptic gauze into an aseptically prepared bottle of considerable size—one holding thirty to forty ounces preferred—and the rubber stopper of the aspirator adjusted By reversal of the instrument, the air in the bottle is compressed, and the bottle, held cork down, is ready for use. The No. 1 or 2 aspirator needle is easily introduced into the median cephalic vein without cutting, and when the end is free in the vein the connection with the bottle is made, first letting a little milk escape to ensure absence of air. The intravenous injection of milk or saline fluids is thus simple and easy, and with proper care may be rendered aseptic. Transfusion mediate or immediate is not easy or simple. The dissection of a vein and introduction and tying of a canula in a patient nearly bloodless, perhaps dying, is difficult, and the Aveling instrument, with Dr. Marcy, had been very unsatisfactory even in a series of experiments upon dogs conducted with great care. The aspirator is now a part of the armamentarium of every physician, and by its use as suggested we have at hand a ready and easy method of adding fluid to the circulation which may save life.

In reply to the question as to the advantages which Dr. Marcy had seen coming from intravenous injection, he replied that he believed in all the instances used the patients have ultimately died, but good effects followed temporarily from the injections. They had been used only in desperate cases, and he believed they should be resorted to earlier and oftener than usual. Dr. F. B. Harrington, of Boston, published in the *Boston Medical and Surgical Journal*, of March 4, a case in which sixty-six ounces of a salt solution had been used after a most alarming flooding, and the inference seemed clear that recovery was dependent upon its use. Dr. Marcy had never injected more than ten or twelve ounces of milk at one time; decided improvement of the circulation had followed after the use of six or eight ounces.

DR. MARCY presented an

INTERSTITIAL MULTILOBULAR FIBROID TUMOR

which he had recently removed at his private hospital, assisted by Dr. Cushing, Dr. Corey of Westboro, and Dr. Goodwin, of East Boston. The patient, aged 53, had passed the menopause some years ago, and only within a few months had in any way been a sufferer. Excessive and continuous flowing caused her to consult Dr. Corey. The tumor reached nearly to the umbilicus and was situated in the anterior wall of the uterus. The cervix was obliterated and the os admitted the finger. The uterine wall over the tumor was about one third of an inch in thickness and bled profusely on section, after which the hæmorrhage was slight during the operation. Strong vulsellum forceps were hooked into the tumor, and it was cut away piecemeal, the saw-spoon being used in separating the growth from its investing capsule. It was removed in fourteen sections, and the entire mass weighed four pounds. The operation was conducted under irrigation with a solution of mercuric bichloride, and the cavity filled with Seabury & Johnson's soft iodoform gauze.

The patient rallied well, and during the ten days following operation pulse was nearly normal, after a reaction to temperature of 100 twelve hours after the operation. Without permission the patient walked about her room, during the absence of the nurse, on the tenth day, and a severe perimetritis supervened; recovery from this was less rapid and the patient was discharged convalescent between the fourth and fifth week.

The interest in the operation centres in the size of the growth, since it is very rarely that tumors of this size have been removed per vaginam. Rapidly growing fibroids are also rare after the menopause.

LETTER FROM PARIS

(FROM OUR OWN CORRESPONDENT.)

The Congress of Hydrology and Climatology—Changes in the Pupil after Death—Hydatid Cysts of the Liver—Cardiac Stimulants—New Test for Codeine.

The first International Congress of Hydrology and Climatology will be held at Biarritz, the 1st of October, 1886, under the honorary patronage of the French Minister of Commerce, and the presidence of Dr. Durand-Fardel, the well known hydrologist. The programme states that the aim of this Congress is to bring together in a country rich in thermal and sanitary stations, the learned men of all countries who would study in common the questions bearing on hydrology and climatology. All societies and scientific associations, all learned men in France and abroad are invited to take part in this meeting. Any person wishing to join the Congress must send in his application enclosing a postoffice order for ten shillings, which must reach Paris by the 1st of September at latest in order to entitle the members to a reduction of fifty per cent. on the French railways. They will also enjoy other privileges which are detailed in the programme, which may be obtained from Dr. Durand Fardel, 17 Rue de Guénégaud, Paris, who will be glad to furnish any other information that may be required concerning the Congress.

The *Gazette des Hôpitaux* lately published the following interesting points on the alterations that the pupil undergoes after death, and on the action of atropine and of other alkaloids on the eye of a corpse. In the greater number of cases, the pupils are dilated at the moment of death. The dilatation takes place a very short time before the person has expired. It is produced very rarely a short time after death. The dilatation is of a paralytic nature, and independent of the aspect that it presented during life, whether it was produced by the effects of drugs or by disease. More frequently, after death, a progressive contraction of the pupil is observed, varying within rather extensive limits, both as regards the moment of its appearance and the degrees of the contraction. This contraction ordinarily commences an hour after death and continues forty eight hours afterwards. The myosis, often unequal on both sides, is independent of the action of light and of cadaveric rigidity. The pupil reacts, under the influence of atropine, after death, during a variable time according to the subjects, nearly about four hours when the instillation of atropine is employed, during a longer time, when atropine is injected into posed at his first visit to the patient, but as hæmorrhage was under complete control, and there was no marked indication for such heroic treatment, it was not done He regarded the treatment of the case as judicious He had never seen a case of inversion of the uterus

Dr H C White had never seen a case of inversion of the uterus He thought that shock or some unknown factor must have been the cause of death in Dr Field's second case

Dr W Symington Brown had never seen a case of inversion He did not think the second case described one of partial placenta prævia, but regarded it as more probable that it was a case of interstitial fibroid tumor Monsell's solution is not, in his opinion, a suitable styptic for use where it is necessary to tampon the vagina, as it formed a hard, leathery clot He generally uses boiling water, applied to the bleeding vessels by means of a dressing forceps and a sponge When a styptic is required on a tampon Dr, Brown uses a weak solution of tincture of iodine, and has had good results from such use It is important to combine nutrient materials, such as milk and beef tea, with stimulants where the latter remedies are required, in order that the strength of the patient may be maintained

Dr W Thornton Parker, of Newport, R I, had been much interested in the cases reported He raised the question whether death in the second case was not due to blood clot

Dr C W Stevens thought that transfusion was indicated in the second case when it was evident that the patient was sinking His experience had led him to believe that when the system was suffering from shock, absorption, either by mouth or subcutaneous tissue, was in abeyance, and that the only hope lay in throwing directly into the circulation some material suitable to support the powers of life

Dr A L Norris had seen but one case of partial inversion of the uterus In the second case reported he thought there must have been some unknown factor in producing death, such as interstitial fibroids He regarded the treatment of the case as entirely correct, and did not think that turning was admissible

Dr N O B Wingate had seen no cases of inversion He thought that internal hæmorrhage may have been the cause of death in Dr Field's second case He related a case of sudden death soon after delivery which occurred in his own practice His patient was a large and strong woman, and had been in labor twelve hours She suddenly began to sink, and delivery was hastened by using the forceps, no anæsthetics being used A child weighing 17½ lbs was delivered without very much difficulty The mother rallied well, and everything seemed to be progressing finely After reaching home he was hurriedly called again and found his patient dead The nurse reported that she gasped a few times and died very suddenly Dr Wingate thought death in this case due to heart clot

Dr Harbird asked Dr Field in regard to the amount of ergot given in his second case before the birth of the head He thought that there might have existed a rupture of the uterus which escaped notice but caused death He doubted if the loss of blood caused death, as in many cases it is known that the loss of blood may be very great and yet not destroy life

Dr E W Cushing asked if much hæmorrhage followed peeling off the placenta in the case of inversion A discussion had recently arisen in a medical society as to whether it was best to try to separate the placenta from the uterus while it was extruded, or to replace the uterus and then remove the placenta, the theory being that serious hæmorrhage would follow its removal when the uterus was inverted Dr Cushing said that transfusion was likely to be a disappointing measure in such cases as Dr Field's second case It was no easy operation to perform, and even if successfully accomplished did not often succeed in averting a fatal issue He mentioned the case of a strong and robust man in which transfusion was tried for excessive hæmorrhage from the temporal artery Although the case was a favorable one and the operation was successfully performed, the patient sank and died Dr Cushing thought there was a cause of death in such cases which might be overlooked, *i e*, the gradual formation of a clot in the venous system, beginning at the periphery, and gradually increasing until it interferes with the action of the heart or lungs Œdema of the lungs may be due to this cause

Dr Whitcomb asked if chloral hydrate could be used hypodermically He also raised the question if an idiosyncrasy to ergot did not exist in Dr Field's second case

In reply to queries made by different members during the discussion, Dr Field made the following statements Milk or other nutrient material had not been combined with the brandy on account of constant nausea He did not think that death could have been due to heart clot, as there were no symptoms present which could support such an hypothesis He was of the opinion that transfusion was indicated, and would have tried that means had he had the time and necessary apparatus The amount of ergot given in the second case before the birth of the head was about ʒj in divided doses He knew no evidence to prove that such doses of ergot ever produced toxic effects He did not think that an idiosyncrasy to ergot existed in the case Chloral hydrate could not be administered hypodermically on account of its irritating qualities No hæmorrhage of importance followed peeling off the placenta in the case of inversion

Dr Marcy, in commenting upon Dr Field's case, suggested a method of intravenous injection which he had used quite a number of times with ease and success, and which had never been reported It was the result of many experiments in injection of animals for anatomical purposes under continuous atmospheric pressure Milk is drawn directly from the animal through antiseptic gauze into an aseptically prepared bottle of considerable size—one holding thirty to forty ounces preferred—and the rubber stopper of the aspirator adjusted By reversal of the instrument, the air in the bottle is compressed, and the bottle, held cork down, is ready for use The No 1 or 2 aspirator needle is easily introduced into the median cephalic vein without cutting, and when the end is free in the vein the connection with the bottle is made, first letting a little milk escape to ensure absence of air The intravenous injection of milk or saline fluids is thus simple and easy, and with proper care may be rendered aseptic Transfusion mediate or immediate is not easy or simple The dissection of a vein and introduction and tying of a canula in a patient nearly bloodless, perhaps dying, is difficult, and the Aveling instrument, with Dr Marcy, had been very unsatisfactory even in a series of experiments upon dogs conducted with great care The aspirator is now a part of the armamentarium of every physician, and by its use as suggested we have at hand a ready and easy method of adding fluid to the circulation which may save life

The Congress of Hydrology and Climatology—Changes in the Pupil after Death—Hydatid Cysts of the Liver—Cardiac Stimulants—New Test for Codeine

The first International Congress of Hydrology and Climatology will be held at Biarritz, the 1st of October, 1886, under the honorary patronage of the French Minister of Commerce, and the presidence of Dr Durand-Fardel, the well known hydrologist The programme states that the aim of this Congress is to bring together in a country rich in thermal and sanitary stations, the learned men of all countries who would study in common the questions bearing on hydrology and climatology All societies and scientific associations, all learned men in France and abroad are invited to take part in this meeting Any person wishing to join the Congress must send in his application enclosing a postoffice order for ten shillings, which must reach Paris by the 1st of September at latest in order to entitle the members to a reduction of fifty per cent on the French railways They will also enjoy other privileges which are detailed in the programme, which may be obtained from Dr Durand Fardel, 17 Rue de Guénégaud, Paris, who will be glad to furnish any other information that may be required concerning the Congress

The *Gazette des Hopitaux* lately published the following interesting points on the alterations that the pupil undergoes after death, and on the action of atropine and of other alkaloids on the eye of a corpse In the greater number of cases, the pupils are dilated at the moment of death The dilatation takes place a very short time before the person has expired It is produced very rarely a short time after death The dilatation is of a paralytic nature, and independent of the aspect that it presented during life, whether it was produced by the effects of drugs or by disease More frequently, after death, a progressive contraction of the pupil is observed, varying within rather extensive limits, both as regards the moment of its appearance and the degrees of the contraction This contraction ordinarily commences an hour after death and continues forty eight hours afterwards The myosis, often unequal on both sides, is independent of the action of light and of cadaveric rigidity The pupil reacts, under the influence of atropine, after death, during a variable time according to the subjects, nearly about four hours when the instillation of atropine is employed, during a longer time, when atropine is injected into the anterior chamber Dilatation commences sensibly after the same time, on the dead as well as on the living eye, the action is less durable than in the dead eye The instillation or injection of eserine, after death, produces contraction of the pupil, but for a shorter time than the dilatation which is produced by atropine Instillations of ergotine, after death, produce no change whatever of the pupil, an injection of this substance into the tissue of the iris, or into the anterior chamber, produce a myosis of two hours' duration Pilocarpine has a weak myotic action on the eye after death

In a very interesting paper on the treatment of *Hydatid Cysts of the Liver*, Dr L G Richelot, son of the present editor of the *Union Medicale*, lately published a paper in that journal on the subject He recommends the use of the aspiratory puncture, if only as a means of diagnosis The cyst should be entirely emptied to prevent effusion into the peritoneum In spite of all precautions, the liquid is reproduced, and it is only in exceptional cases that a complete cure is effected by the operation In the majority of cases, however, a relapse is the rule, after one or two punctures, the cyst suppurates, and then, in the event of a return of the disease, a free incision should be resorted to, instead of employing the aspirator, as the repeated use of the latter is not always inoffensive

The ostensible object of the aspirator or the employment of a free incision is to avoid the necessity of making an opening into the peritoneal cavity, but Dr Richelot is of opinion that this would be only tampering with the malady and losing valuable time He therefore recommends that at the very commencement, and when the diagnosis of a hydatid cyst of the liver has been established, a free incision into the peritoneum should be practised, employing at the same time the usual necessary precautions By this means the surgeon is enabled to examine the tumor more completely, and to decide as to the proper subsequent treatment that should be adopted When it is decided to cut through the peritoneum, Dr Richelot adopts the method of Volkmann, that is to say, a modified laparotomy, which is an operation not dangerous in itself, and it has the advantage of enabling the surgeon to see what he is doing

The author concludes his paper by laying down certain rules for the treatment of hydatid cysts of the liver which have returned after the capillary puncture 1 Free incision of the peritoneum with antiseptic precautions 2 Exploration of the tumor 3 Treatment of the cyst appropriate to its size and its connections

In a memoir by Dr Durand, of Lille, on *Cardiac Stimulants*, and to which a prize has been awarded by the Catholic Faculty of that city, the author gives some valuable information on adonidine, and compares its action with that of other drugs, such as digitalis, convallaria, and caffeine According to the author, adonidine acts on the heart somewhat like digitalis, but it possesses no cumulative properties, its diuretic effects are very marked, and it can be used for a long time without causing any symptoms of intolerance It should be given at a dose of 2 centigrammes, when the beats of the heart are irregular or unequal, digitalis is the best remedy, and adonidine is much less useful On the other hand the latter gives good results in all cases where the arterial tension is too low As a diuretic, caffeine is to be preferred

M Lafon describes, in a paper read by him at the Academy of Sciences, a *New Test for Codeine*, as follows If a trace of codeine be mixed with a solution of one gramme of ammonium selenite in twenty cubic centimetres of sulphuric acid, a beautiful green color is obtained, which gradually changes by oxidation to a reddish brown, one milligramme of codeine can be detected in this way The reaction is not yielded by any other active principle, alkaloid or glucoside, except morphine A B

DOMESTIC CORRESPONDENCE

CARBOLIC ACID INJECTIONS IN CARBUNCLE

To the Editor of the Journal

Dear Sir —In the number of The Journal for February 13, 1886, page 185, I noticed quotations from an article in the *Texas Medical Journal*, of November, 1885, in which Dr Wilkinson, of Galveston, states that for the last six or eight years he has used carbolic acid by injection in the treatment of carbuncle In connection with his suggestion I deem it proper to note the fact that in the *Toledo Medical and Surgical Journal*, for 1880, I published an article on this subject, of which the following extract is the conclusion

"It is now about two years and a half since a patient presented with two carbuncles, one on the back of the head, the other below it on the neck They were of moderate size only, the upper being open in three places, while in the lower the skin was unbroken

"Having considered the various known properties of carbolic acid, I determined to use it in the sinuses of the upper carbuncle, and to use it vigorously Loading my hypodermic syringe and passing the point through the opening and into the sloughing mass in every direction, I completely saturated it with the pure acid, and awaited results In a minute the smarting disappeared, and with it all pain and sense of soreness

"By this result emboldened, I again charged the instrument and thrusting it through the skin over the other carbuncle in a variety of places, I soaked the whole mass beneath the skin, enough of necessity escaping to fully bathe the borders, modify inflammation and destroy any septic elements there developed I waited not without concern, and was delighted to learn in a few moments that all pain and soreness was gone in this also The skin over the mass became quickly white, hard and dead, in a few days detaching in the form of slough, the interior mass also becoming loosened and only requiring the cutting of a few shreds to remove it, when the cavity was found to present a satisfactory appearance, and rapidly filling up left an exceedingly small cicatrix

"The remarkable feature in this case was that after the complete saturation of the carbunculous mass, no pain occurred, my patient going about his ordinary labor without discomfort It is now but a year since I treated another case in a similar manner, with similar results, the party suffering no pain or even soreness after the lapse of one minute following the injection

"In making this suggestion, which so far as I know is new, I am conscious of the insufficiency of my cases, but I am so sure of its efficiency that I shall at once resort to it when case and occasion offer, and advise others to do so, at least until the value of the measure is determined In conclusion, I would advise the use of pure acid only, and to complete saturation, dilution would increase, if not create, danger of absorption, converting a very simple procedure into one of great danger, and being insufficient, defeat the purpose for which it is used "

Since writing the above, experience has fully confirmed me in the correctness of all set forth, and I had come to regard it as an important fact and congratulated myself that I had at least, as a prior observer, given this much to my profession I care little about that point, however, but still think that I may claim that much But whoever was the first, it was independently used by me in the office in which I write this note, with some misgivings as to consequences Double discoveries are always possible, but in my case they have been quite striking I supposed myself to be the first to use the continuous pressure of rubber in chronic orchitis, applying the common rubber capote I also made from a pair of pruning shears the first costatome of which I ever heard, and that, too, long before any note of them appeared in the illustrated circulars of instrument manufacturers, and invented and had made a device by which the piston head in a syringe cylinder can be made larger and smaller at will without removal from the barrel These devices I showed freely to many traveling men and others, and soon the back counties were heard from Some fellow patented the syringe device, and it is now manufactured by Lutz, of Indianapolis, and offered to the profession with a flourish of trumpets as to its merits I have in my possession the original instrument, made years before the issuance of the patent, the merit of invention having been coolly filched from me

Truly yours, J T Woods, M D

Toledo, Ohio, February 28, 1886

TREATMENT OF CARBUNCLE

To the Editor of the Journal

Dear Sir —Your editorial remarks in The Journal of February 13, 1886, in regard to the treatment of carbuncle by the injection of carbolic acid, full strength, as suggested by C H Wilkinson, M D, in *Daniel's Medical Journal* for November, 1885, p 15, are timely, and the benefit of the treatment is confirmed by the success I have attained in the several cases in which I have used it A few facts in regard to my methods, additional to the carbolic acid treatment, may not be out of place I invariably test the urine for sugar when first undertaking the treatment of a patient for carbuncle If sugar be present, I put the patient on strict diabetic diet, and prescribe bromide of arsenic, three drops, twice a day, and inject the sinuses of the carbuncle with carbolic acid, full strength If I do not find sugar in the urine I conclude, as to the etiology of the disease, that it is the retention in the alimentary canal of excrementitious matter and the consequent poisoning of the system The diet is temporarily restricted, and cathartics administered until the stomach and bowels are thoroughly unloaded, after which I give

℞ Permanganate of potash gr ss
Water ℥ij
M Sig At once

and repeat the dose until I am satisfied that the alimentary canal is thoroughly disinfected I have never failed to cure carbuncle by this method, and thus far have not had a recurrence of the disease in a single case The following are the only cases I will claim space to report

Case 1 —Mrs McC, about 43 years of age, white, married, and the mother of one child She is of fine physique and generally good health She had suffered from carbuncle for a number of months, and had submitted to various methods of treatment, and about as soon as one carbuncle was cured, another made its appearance Each successive carbuncle appeared a little higher up the back, the last one being near the nape of the neck It was about three inches in diameter and had two sinuses The test of urine for sugar gave negative results I administered brisk cathartics and then gave permanganate of potash, and refused to cut the carbuncle In a few days she was well, and there has been no recurrence of the disease after the lapse of a year

Case 2 —On February 12, 1886, James Owens applied to me for treatment of carbuncle He was about 40 years of age, white, a native of Texas, unmarried, and a farmer The carbuncle was situated on the back, in the lumbar region and near the mesal line, and was three and one half inches in diameter There were three deep sinuses, and the parts were highly inflamed and painful He had lost flesh, had no appetite, and complained of giddiness I injected carbolic acid deeply into all three sinuses, gave him cathartics and followed them with permanganate of potash In a few days he reported himself well

I am convinced of the beneficent effects of the carbolic acid treatment, but to insure a non return of the malady, I am equally convinced of the necessity of disinfecting the alimentary canal, where sugar in the urine is not found among the etiological factors

I am, very truly, J W Carhart, M D

Lampasas, Texas

THE MECHANICAL TREATMENT OF THE VOMITING OF PREGNANCY

To the Editor of the Journal

Dear Sir —In Dr Joseph Taber Johnson's paper, read before the Medical Society of the District of Columbia, and published in The Journal of March 13, he says, on page 288 "In the *London Lancet*, uræmic convulsions, for example, nothing is said as to the use of morphia subcutaneously, which reminds us that the work is singularly deficient in references to American authors and their work The name of Dr Flint does occur in the index of authors, but his residence is given as *Philadelphia* But there are many names of European authors missing from the list which should appear in a pretentious work Again, in the treatment of peritonitis, while opium is recommended, nothing is said of the use of morphia, regarded by many practitioners as far preferable to opium Surely the work of Dr Alonzo Clark should have been thought worthy of mention in this place We read that "for the actual paroxysm of ague but little treatment is needed" On the contrary, very active treatment is often urgently necessary No reference is made to the fact that a subcutaneous injection of morphia will arrest the paroxysm, and prevent many of the disagreeable and it may be in some cases very injurious effects Hot water bottles are all well enough *after* the morphia has been given, if we choose to go to an unnecessary trouble (for they must be removed when the morphia takes effect) Singularly enough the use of mercury in small doses in pernicious anæmia, written of by an Englishman two years ago, is not mentioned In short, the treatment given throughout the book is unsatisfactory This, however, is what might be expected when we see that the references to German literature are so numerous

On the manner in which the etiology, diagnosis and pathology of diseases have been dealt with scarcely too much can be said in praise There are some who will take exception to the author's classification of Bright's disease, but an equal or greater number will concur in it The tests for albumin in the urine are insufficiently given, and should surely have been corrected by the Editor There are other very surprising omissions by the Editor Thus in the note on cholecystotomy his last reference to Lawson Tait's work in this field is to a paper published in 1880

It only remains to say that the work can only be recommended as one for reference, and for this it is of great value, especially for those who teach ante

ASSOCIATION ITEMS

MEMBERS BY APPLICATION AND THE ANNUAL MEETING

I have received several letters from gentlemen who have become members of the Association by application under the provision recently enacted, desiring information as to their status at the annual meetings of the Association I have also been the recipient of inquiries from others who wish to become members at the coming meeting at St Louis through the same channel, that is by application I will briefly say that those who are already members of the Association, under the new regulation allowing members of State and local societies to become such upon application endorsed by the President and Secretary of such society, are Permanent Members of the Association, and continue as such so long as they remain in good standing in their State or local society and pay their annual dues to the Association When they attend an annual meeting, they register either as delegates from their original Society, if they have been so elected (with the right of voting), or as Permanent Members (without the right of voting)

Gentlemen who wish to become members of the Association by application at the St Louis meeting, and who do not attend as delegates, will fill up the usual registration blanks, and present, with the five dollars for dues, a certificate signed by the President and Secretary of their State or local Society, stating that they are members, in good standing, of such Society

As vacancies doubtless exist in some of the delegations to St Louis in different parts of the country, possibly some of the Permanent Members and also those desirous of becoming such by application, may be able to obtain appointment as delegates to fill such vacancies

Richard J Dunglison, M D,
Treasurer

Philadelphia, April 13, 1886

AMERICAN MEDICAL ASSOCIATION

The Thirty-seventh Annual Session will be held in St Louis, Mo, on Tuesday, Wednesday, Thursday and Friday, May 4, 5, 6 and 7, commencing on Tuesday at 11 A M

The delegates shall receive their appointment ermanently organized State Medical Societies and District Medical Societies *as tion in their respective* epartment of ital Service of disease and death as may be useful in the discharge of the duties of said Board It shall be the duty of all local boards of health, health authorities and officials, officers of State institutions, police officers, sheriffs, constables, and all other officers and employés of the State, or any county, city or town thereof, to make and enforce such quarantine and sanitary rules and regulations, as the public health may require, in so far as the success and efficiency of the Board of Health may depend thereon, and in the event of failure or refusal on the part of any member of said Boards, or other officials or persons in this section mentioned to so act, he or they shall be subject to a fine of not less than fifty dollars upon first conviction, and upon a conviction of second offense of not less than one hundred dollars

Sec 3 The Board of Health shall have supervision of the State system of registration of births and deaths, they shall make up such forms and recommend such legislation as shall be deemed necessary for the thorough registration of vital and mortuary statistics throughout the State The Secretary of the Board shall be the superintendent of such registration The clerical duties and the safe keeping of the bureau of vital statistics thus created shall be provided by the Secretary of State

Sec 4 It shall be the duty of boards of health, health authorities or officials, and of physicians in localities where there are no health authorities or officials, to report to the State Board of Health, promptly upon discovery thereof, the existence of any one of the following diseases which may come under their observation, to wit Asiatic cholera, yellow fever, small-pox, scarlet fever, diphtheria, typhus fever, and of such other contagious or infectious diseases as the State Board may from time to time specify

Sec 5 All amounts recovered under the penalties herein provided, shall be appropriated to a special fund for the carrying out of the object of this law

Sec 6 The first meeting of the Board shall be within thirty days after their appointment, and thereafter in January and June of each year, and at such other times as the Board shall deem expedient The meeting in January of each year shall be in Columbus A majority shall constitute a quorum They shall choose one of their number to be president, and they may adopt rules and by laws for their government, subject to the provisions of this act

Sec 7 They shall elect a Secretary who shall perform the duties prescribed by the Board and by this act, and who shall upon cause, be removed by a majority vote, he shall receive a salary not exceeding $1600, which shall be fixed by the Board, he shall also receive his traveling and *other expenses incurred* in the performance of his official duties The other members of the Board shall receive five dollars per day, and their traveling and other expenses while employed on business of the Board The President of the Board shall, quarterly, certify the amount due the members, and on presentation of his certificate the Auditor of State shall draw his warrant on the Treasurer for the amount

Sec 8 It shall be the duty of the Board of Health to make an annual report, through their Secretary or otherwise, in writing, to the Governor of the State, on or before the 1st day of November of each year, and such report shall include so much of the proceedings of the Board, and such information concerning vital statistics, such knowledge respecting diseases, and such instructions on the subject of hygiene, as may be thought useful by the Board for dissemination among the people, with such suggestions as to legislative action as they may deem necessary

Sec 9 The sum of five thousand dollars ($5000 - 00), or so much thereof as may be necessary, is hereby appropriated to pay the salary of the Secretary, meet the contingent expenses of the office of the Secretary, and expenses of the Board, and all costs of printing, which, together, shall not exceed the sum hereby appropriated, said expenses shall be certified and paid in the same manner as the salary of the Secretary

Sec 10 The Adjutant general shall provide rooms suitable for the meetings of the Board, and office room for the Secretary

Sec 11 This act shall take effect and be in force from and after its passage

BOOK REVIEWS

The Principles and Practice of Medicine By the late Charles Hilton Fagge, M D , F R C P , Physician to, and Lecturer on Pathology at, Guy's Hospital, Examiner in Medicine in the University of London, Senior Physician to the Evelina Hospital for Sick Children, etc Edited by P H Pye-Smith, M D , F R C S , Lecturer on Medicine at Guy's Hospital, including a Section on Cutaneous Diseases, by the Editor, Dr Pye Smith , Chapters on Cardiac Diseases, by Samuel Wilkes, M D , F R S , Physician to Guy's Hospital and to the Royal Hospital for Children London, and Complete Indexes, by Robert Carrington, M D , Assistant Physician to Guy's Hospital, London Vol II, pp XVI, 17–883 Philadelphia P Blakiston, Son & Co 1886

This, the second volume of Dr Fagge's work, deals with diseases of the Heart, the Digestive Organs, Liver, Spleen, and Kidneys, and of the Bones, Joints, Blood and Skin There is, we think, more to be said in praise of this than of the first volume Much of the matter in the second volume is by writers who have had the opportunity of revising their own proof-sheets, and what they have written was only recently written, whereas much of the matter written by Dr Fagge was prepared some time before his death Many of the sections were left in an unfinished state at his death, and these have been completed, in an admirable manner, by the Editor and Dr Wilkes, and at times it is rather difficult to say whether we are reading after Dr Fagge, Dr Pye Smith, or Dr Wilkes

In many respects this work is very valuable for reference Of the treatment advised in it there is but little to be said In discussing the treatment of for February, 1878, Dr M O Jones, of Chicago (who now resides in Pittsburgh, Pa), published a paper on 'Vomiting of Pregnancy,' and advocated in certain cases the local application of the nitrate of silver to the os uteri as a cure This mode of treatment *could not have originated* with Dr Jones, as Dr Marion Sims reported a case a number of years prior to Jones's paper "in which he cured a noble lady of Paris who had been given over to die by a number of eminent physicians, who had religious scruples against the induction of abortion Sims reports that from the first application the relief was marked, and in a few days she was completely cured The recovery was heralded as little less than a miracle "

Dr J Taber Johnson *could not have* read the paper mentioned, else he *would not* have fallen into an error If Dr Johnson will refer to a number of the *Lancet*, of February, 1878, containing my paper, or to the American reprint of the *Lancet*, May, 1878, he will find what Dr Sims wrote upon the subject in his notes of a case appended to my paper His preliminary remarks to, and the closing paragraph of his notes, I will quote in full

"*Notes of a Case by Marion Sims* —I had the good fortune to meet Dr Jones, of Chicago, last June (1877), when he incidentally related to me his experience in the treatment of the vomiting of pregnancy I thought the matter of so much importance that I begged him to write it out for publication Accordingly he sent me the foregoing paper, which I received just as I was leaving home, and not having time to arrange for its publication then, I now send it to *The Lancet* I am not in the way of seeing much of this affection, but a case came under my observation a *few days* ago so strongly confirmatory of Dr Jones's views, that I take the liberty of appending it to *his paper* After relating the case he closes by saying 'If Dr Jones's treatment acts as promptly in all other cases as it did in mine, the profession will certainly feel grateful to him for it '"

Dr Johnson, after referring to Dr Sims's case, says "I have had one such case, and was greatly surprised by my perfect success in curing a patient who had been confined to bed for two weeks The efforts to vomit continued and were not relieved until the nitrate of silver was applied She immediately became better, and the vomiting soon stopped, and she finally gave birth to a fine healthy child " I am glad to learn of Dr Johnson's successful treatment of a case of vomiting in pregnancy by the means suggested in my paper, and would suggest that had the same treatment been employed in the case of Mrs X , of his paper, she might have been delivered at full time of a "fine healthy child " I remain very truly, M O Jones, M D

Pittsburgh, Pa , March 27

GIFTS TO DOCTORS FROM PATIENTS

To the Editor of the Journal

Dear Sir —The case of Woodbury *vs* Woodbury, decided by the Supreme Court of Massachusetts March 10, 1886, is one of some importance to medical men In that case the intestate before her death gave to the defendant certain sums of money, and the evidence tended to show that previous to and at the time of the gift the intestate was in a feeble mental condition and of advanced age The defendant was the physician, friend, adviser, and fiducial agent of the intestate, managed her affairs, and had considerable influence over her He was not a relative of the intestate Upon this state of facts it was held that the evidence, if believed by the jury, would justify a finding that the defendant in some form solicited the gift and used undue influence to obtain it, and that undue influence may be inferred from the nature of a transaction alone

There can be no doubt of the correctness of this decision Physicians who, under such circumstances, accept gifts from their patients, assume the burden of showing affirmatively the entire fairness of the transaction and that no undue influence has been used M D Ewell, M D,

Medico Legal Counsel

170 Washington St , April 9, 1886

STATE MEDICINE

STATE BOARD OF HEALTH OF OHIO

The following is the Bill recently passed to create and establish a State Board of Health in the State of Ohio

Section 1 *Be it enacted by the General Assembly of the State of Ohio,* That the Governor, with the advice and consent of the Senate, shall appoint seven persons, who (with the attorney-general, who shall be *ex officio* a member of said Board) shall constitute the State Board of Health, provided, that the terms of office of the seven first appointed shall be so arranged that the term of one shall expire on the 13th day of December of each year, and the vacancies so created, as well as all vacancies occurring otherwise, shall be filled by the Governor, with the advice and consent of the Senate, and provided also, that appointments made when the Senate is not in session, may be confirmed at its next ensuing session

Sec 2 The State Board of Health shall have the supervision of the interests of the health and life of the citizens of the State They shall make careful inquiry in respect to the cause of disease, and especially the invasion or spread of any infectious or contagious, epidemic, or endemic disease, and investigate the sources of mortality, and the effects of localities, employments, conditions, ingesta habits, and surroundings on the health of the people, and shall investigate the causes of diseases occurring among the stock and domestic animals of the State, the methods of remedying the same by quarantine or otherwise, and shall gather information in respect to such matters, and kindred subjects for dissemination among the people They shall advise officers of Government, or other State Boards, in regard to the location, drainage, water supply, disposal of excreta, heating and ventilating of public buildings They shall collect and preserve such information relating to forms of disease and death as may be useful in the discharge of the duties of said Board It shall be the duty of all local boards of health, health authorities and officials, officers of State institutions, police officers, sheriffs, constables, and all other officers and employés of the State, or any county, city or town thereof, to make and enforce such quarantine and sanitary rules and regulations, as the public health may require, in so far as the success and efficiency of the Board of Health may depend thereon, and in the event of failure or refusal on the part of any member of said Boards, or other officials or persons in this section mentioned to so act, he or they shall be subject to a fine of not less than fifty dollars upon first conviction, and upon a conviction of second offense of not less than one hundred dollars

Sec 3 The Board of Health shall have supervision of the State system of registration of births and deaths, they shall make up such forms and recommend such legislation as shall be deemed necessary for the thorough registration of vital and mortuary statistics throughout the State The Secretary of the Board shall be the superintendent of such registration The clerical duties and the safe-keeping of the bureau of vital statistics thus created shall be provided by the Secretary of State

Sec 4 It shall be the duty of boards of health, health authorities or officials, and of physicians in localities where there are no health authorities or officials, to report to the State Board of Health, promptly upon discovery thereof, the existence of any one of the following diseases which may come under their observation, to wit Asiatic cholera, yellow fever, small-pox, scarlet fever, diphtheria, typhus fever, and of such other contagious or infectious diseases as the State Board may from time to time specify

Sec 5 All amounts recovered under the penalties herein provided, shall be appropriated to a special fund for the carrying out of the object of this law

Sec 6 The first meeting of the Board shall be within thirty days after their appointment, and thereafter in January and June of each year, and at such other times as the Board shall deem expedient The meeting in January of each year shall be in Columbus A majority shall constitute a quorum They shall choose one of their number to be president, and they may adopt rules and by laws for their government, subject to the provisions of this act

Sec 7 They shall elect a Secretary who shall perform the duties prescribed by the Board and by this act, and who shall upon cause, be removed by a majority vote, he shall receive a salary not exceeding $1600, which shall be fixed by the Board, he shall also receive his traveling and *other expenses incurred* in the performance of his official duties The other members of the Board shall receive five dollars per day, and their traveling and other expenses while employed on business of the Board The President of the Board shall, quarterly, certify the amount due the members, and on presentation of his certificate the Auditor of State shall draw his warrant on the Treasurer for the amount

Sec 8 It shall be the duty of the Board of Health to make an annual report, through their Secretary or otherwise, in writing, to the Governor of the State, on or before the 1st day of November of each year, and such report shall include so much of the proceedings of the Board, and such information concerning vital statistics, such knowledge respecting diseases, and such instructions on the subject of hygiene, as may be thought useful by the Board for dissemination among the people, with such suggestions as to legislative action as they may deem necessary

Sec 9 The sum of five thousand dollars ($5000 00), or so much thereof as may be necessary, is hereby appropriated to pay the salary of the Secretary, meet the contingent expenses of the office of the Secretary, and expenses of the Board and all costs of printing, which, together, shall not exceed the sum hereby appropriated, said expenses shall be certified and paid in the same manner as the salary of the Secretary

Sec 10 The Adjutant general shall provide rooms suitable for the meetings of the Board, and office room for the Secretary

Sec 11 This act shall take effect and be in force from and after its passage

BOOK REVIEWS

The Principles and Practice of Medicine By the late Charles Hilton Fagge, M D , F R C P , Physician to, and Lecturer on Pathology at, Guy's Hospital, Examiner in Medicine in the University of London, Senior Physician to the Evelina Hospital for Sick Children, etc Edited by P H Pye-Smith, M D , F R C S , Lecturer on Medicine at Guy's Hospital, including a Section on Cutaneous Diseases, by the Editor, Dr Pye Smith , Chapters on Cardiac Diseases, by Samuel Wilkes, M D , F R S , Physician to Guy's Hospital and to the Royal Hospital for Children London, and Complete Indexes, by Robert Carrington, M D , Assistant Physician to Guy's Hospital, London Vol II, pp XVI, 17–883 Philadelphia P Blakiston, Son & Co 1886

This, the second volume of Dr Fagge's work, deals with diseases of the Heart, the Digestive Organs, Liver, Spleen, and Kidneys, and of the Bones, Joints, Blood and Skin There is, we think, more to be said in praise of this than of the first volume Much of the matter in the second volume is by writers who have had the opportunity of revising their own proof-sheets, and what they have written was only recently written, whereas much of the matter written by Dr Fagge was prepared some time before his death Many of the sections were left in an unfinished state at his death, and these have been completed, in an admirable manner, by the Editor and Dr Wilkes, and at times it is rather difficult to say whether we are reading after Dr Fagge, Dr Pye Smith, or Dr Wilkes

In many respects this work is very valuable for reference Of the treatment advised in it there is but little to be said In discussing the treatment of uræmic convulsions, for example, nothing is said as to the use of morphia subcutaneously, which reminds us that the work is singularly deficient in references to American authors and their work The name of Dr Flint does occur in the index of authors, but his residence is given as *Philadelphia* But there are many names of European authors missing from the list which should appear in a pretentious work Again, in the treatment of peritonitis, while opium is recommended, nothing is said of the use of morphia, regarded by many practitioners as far preferable to opium Surely the work of Dr Alonzo Clark should have been thought worthy of mention in this place We read that "for the actual paroxysm of ague but little treatment is needed" On the contrary, very active treatment is often urgently necessary No reference is made to the fact that a subcutaneous injection of morphia will arrest the paroxysm, and prevent many of the disagreeable and it may be in some cases very injurious effects Hot water bottles are all well enough *after* the morphia has been given, if we choose to go to an unnecessary trouble (for they must be removed when the morphia takes effect) Singularly enough the use of mercury in small doses in pernicious anæmia, written of by an Englishman two years ago, is not mentioned In short, the treatment given throughout the book is unsatisfactory This, however, is what might be expected when we see that the references to German literature are so numerous

Of the manner in which the etiology, diagnosis and pathology of diseases have been dealt with scarcely too much can be said in praise There are some who will take exception to the author's classification of Bright's disease, but an equal or greater number will concur in it The tests for albumin in the urine are insufficiently given, and should surely have been corrected by the Editor There are other and very surprising omissions by the Editor Thus in a foot-note on cholecystotomy his last reference to Lawson Tait's work in this field is to a paper published in 1880

It only remains to say that the work can only be recommended as one for reference, and for this it is one of great value, especially for those who teach or write

THE METHODS OF BACTERIOLOGICAL INVESTIGATION By DR FERDINAND HUEPPE, Docent in Hygiene and Bacteriology in the Chemical Laboratory of R Fresenius, at Wiesbaden Translated by HERMANN M BIGGS, M D, Instructor in the Carnegie Laboratory, etc Illustrated Pp 218 New York D Appleton & Co 1886

Of the many books that have appeared in the last year or two on this subject, this is one of the best The scope of the book can be learned from the following main headings Spontaneous Generation and the Principles of Sterilization Forms of Bacteria and Microscopic Technique Culture Methods Pure Cultures Inoculations for the Determination of the Causal Relations of Bacteria Growth to Decomposition and Disease General Biological Problems Special Hygienic Investigation Bacteriology as an Object of Instruction

In this book all the approved methods of investigation have been described The translation is good For those desiring to work in this field no better book could be had

---

ASSOCIATION ITEMS

MEMBERS BY APPLICATION AND THE ANNUAL MEETING

I have received several letters from gentlemen who have become members of the Association by application under the provision recently enacted, desiring information as to their status at the annual meetings of the Association I have also been the recipient of inquiries from others who wish to become members at the coming meeting at St Louis through the same channel, that is by application I will briefly say that those who are already members of the Association, under the new regulation allowing members of State and local societies to become such upon application endorsed by the President and Secretary of such society, are Permanent Members of the Association, and continue as such so long as they remain in good standing in their State or local society and pay their annual dues to the Association When they attend an annual meeting, they register either as delegates from their original Society, if they have been so elected (with the right of voting), or as Permanent Members (without the right of voting)

Gentlemen who wish to become members of the Association by application at the St Louis meeting, and who do not attend as delegates, will fill up the usual registration blanks, and present, with the five dollars for dues, a certificate signed by the President and Secretary of their State or local Society, stating that they are members, in good standing, of such Society

As vacancies doubtless exist in some of the delegations to St Louis in different parts of the country, possibly some of the Permanent Members and also those desirous of becoming such by application, may be able to obtain appointment as delegates to fill such vacancies

RICHARD J DUNGLISON, M D,
Treasurer

Philadelphia, April 13 1886

AMERICAN MEDICAL ASSOCIATION

The Thirty-seventh Annual Session will be held in St Louis, Mo, on Tuesday, Wednesday, Thursday and Friday, May 4, 5, 6 and 7, commencing on Tuesday at 11 A M

The delegates shall receive their appointment from permanently organized State Medical Societies and such County and District Medical Societies *as are recognized by representation in their respective State Societies*, and from the Medical Department of the Army and Navy, and the Marine Hospital Service of the United States

Each State, County, and District Medical Society entitled to representation shall have the privilege of sending to the Association one delegate for every ten of its regular resident members, and one for every additional fraction of more than half that number *Provided*, however, that the number of delegates for any particular State, territory, county, city or town shall not exceed the ratio of one in ten of the resident physicians who may have signed the Code of Ethics of the Association

Secretaries of Medical Societies, as above designated, are earnestly requested to forward, *at once*, lists of their delegates

Also, that the Permanent Secretary may be enabled to erase from the roll the names of those who have forfeited their membership, the Secretaries *are, by special resolution*, requested to send to him, annually, a corrected list of the membership of their respective Societies

SECTIONS

"The Chairman of the several Sections shall prepare and read, in the general sessions of the Association, papers on the advances and discoveries of the past year in the branches of science included in their respective Sections "—*By-Laws*, Art 11, Sec 4.

Practice of Medicine, Materia, Medica and Physiology —Dr J T Whittaker, Cincinnati, Ohio, *Chairman*, Dr B L Coleman, Lexington, Ky , *Secretary*

Obstetrics and Diseases of Women and Children —Dr S C Gordon, Portland, Me , *Chairman*, Dr J F Y Paine, Galveston, Texas *Secretary*

Surgery and Anatomy —Dr Nicholas Senn, Milwaukee, Wis , *Chairman*, Dr H H Mudd, St Louis, Mo , *Secretary*

State Medicine —Dr John H Rauch, Springfield, Ill , *Chairman*, Dr F E Daniel, Austin, Texas, *Sec'y*

Ophthalmology, Otology, Laryngology —Dr Eugene Smith, Detroit, Mich , *Chairman*, Dr J F Fulton, St Paul, Minn , *Secretary*

Diseases of Children —Dr W D Haggard, Nashville, Tenn *Chairman*, Dr W B Lawrence Batesville, Ark *Secretary*

Oral and Dental Surgery —Dr John S Marshall, Chicago Ill., *Chairman*, Dr A E Baldwin, Chicago, Ill , *Secretary*

A member desiring to read a paper before a Section should forward the paper, or its *title* and *length* (not to exceed twenty minutes in reading), to the Chairman of the Committee of Arrangements, at least one month before the meeting —*By-Laws*

Committee of Arrangements —Dr Le Grand Atwood, St Louis, Missouri, *Chairman*

AMENDMENTS TO BY-LAWS

By Dr Foster Pratt, Mich —Each Section shall nominate its Chairman and Secretary—all other nominations to be made as now, by the nominating Committee

By Dr I N Quimby, N J—Create a new Section, to be known as the Section on Medical Jurisprudence

Wm B Atkinson, M D ,
Permanent Secretary
1400 Pine St , S W cor Broad, Philadelphia.

The Section on Practical Medicine —The Chairman of the Section on Practice, Physiology and Materia Medica begs to call the attention of members to the unusual array of essays and reports to be presented at the ensuing convention at St Louis Papers are already announced by Drs Wm Pepper, of Philadelphia, on "Nitrate of Silver in Catarrhal Jaundice," L Duncan Bulkley, of New York, on "The Treatment of Felon without Incision," C Warrington Earle, of Chicago, on "Pancreatic Anæmia," L Bremer, of St Louis, on "Essential Vertigo," Albert C Haven, of Lake Forest, Ill , on the "Etiology of Disease," Jno B Elliott, of New Orleans, on "Fever," F H Patten of the National Military Home of Dayton, Ohio, on "Pneumonia in the Old," Philip Zenner, of Cincinnati, on the "Diagnostic Value of the Patellar Tendon Reflex," A F Pattee of Boston, on "Potassium Chloride," O F Schultz, of Mt Vernon, Ind , on the "Use of Antipyretic Doses of Quinia in Typhoid Pneumonia," Edward F Wells, of Minster, O , on "Pneumonia in Pregnancy," and Frederick N Huehn, of Rockland, Maine, on "The Effects of Certain Physiological Principles hitherto Unnoticed in Aid of the Circulation of the Blood "

The session of May 6 will be partly devoted to a demonstration with the cabinet of the principles of "Pneumatic Differentiation," by H F Williams, of Brooklyn, to be followed by a general discussion of pneumatic methods to be opened by E Fletcher Ingals, of Chicago

Some time during the convention, date to be announced, Dr Joseph Jones, of New Orleans, will give a brief record of sixteen years' clinical experience in the Charity Hospital of New Orleans, and Dr S S Laws will read a paper on "The Life and Labors of Louis Pasteur "

The mention of the subjects to be presented with the names of the authors, must command unusual attendance and interest in the work of this Section

J T Whittaker, M D ,
Chairman

April 19, 1886

Railway Certificates to the Association Meeting—Special Notice —To delegates and others who will attend the meeting of the American Medical Association, St Louis, May 4 to 8 Parties located east of Buffalo, Niagara Falls, Pittsburgh and Parkersburg, will apply by mail to Secretary of Trunk Line Committee, 346 Broadway, N Y , for certificates Parties west of points named above and east of the Mississippi River, and north of the Ohio River, will apply to Geo H Daniels, Commissioner C P C , Chicago Ill , for certificates Parties south of the Ohio River, and east of the Mississippi River, will apply to M Slaughter, Commissioner, Richmond, Va. Parties from Missouri River points, and from Chicago, will apply to E P Wilson, Arbitrator, Chicago Points in the west and local points on the lines centering in St Louis will be arranged for, by agent at starting point or upon arrival here

Delegates in making application to the above named persons for a certificate, must not forget to enclose a two cent stamp to pay postage on the return letter enclosing to them the certificate This must be done to insure the certificate being sent.

Any delegate who fails, after making every effort, to get a certificate in due form, will take a receipt from the ticket agent at the point from which he starts, for amount of full fare paid by him, coming to the meeting, and in this receipt be particular to have named the form and number of ticket, and the road over which he will come If not directly on one of the lines entering into this arrangement of reduced rates, pay your fare only to it, and then pay your full fare from that point, securing your certificate or receipt as above directed State, County or City Societies can apply for the number of certificates they may wish, and have the number wanted sent in one envelope instead of applying individually

Round trip tickets from Chicago, Ill, also from New York (339 Broadway), Richmond, Va, and Washington City, D C, by Chesapeake & Ohio Railroad, from Philadelphia via Penn Central and B & O

Members of the American Medical Association, or members of any medical societies, who may see the above, will please report it to individual members, or their societies, and try to get a notice of same in their city or county newspaper

R M JORDAN, M D,
Chairman Transportation Committee
St Louis Mo

RAILWAY FACILITIES TO THE ASSOCIATION MEETING —The regular through trains of the Illinois Central Railroad from Chicago to St Louis will afford excellent accommodations for delegates who wish to attend the meeting of the American Medical Association at St Louis the first week in May The night express, with Pullman sleeping cars, leaves Chicago at 8 30 P M, and arrives in St Louis at 7 A M The rates are $7 50 round-trip

The rates on the Baltimore and Ohio Railway for those coming from the East and South east are full fare coming and one third fare returning

The Illinois Central, Chicago and Alton, and the Wabash Railways have agreed to fix the rates from Chicago to the meeting of the Association, for members, at $7 50 *round trip*

RUSH MONUMENT COMMITTEE —The standing committee, charged with the erection of a monument in the city of Washington, to Dr Benjamin Rush, by the members of the profession of Medicine in the United States, will meet on Monday, May 3d, at 4 o'clock P M, in the large parlor of the Lindell House, St Louis, Mo, which will be the headquarters of the committee during the session of the Association

ALBERT L GIHON, M D,
Chairman
GEORGE H ROHE, M D, *Sec'y*

RAILROAD FARES —The Boston & Albany Rail road will, upon application at their office, 232 Washington St, Boston, sell to delegates and *their families* tickets to St Louis and return for one and one-third fares for round trip A parlor car, to run through from Boston to St Louis, will be attached to the train leaving Boston at 3 P M, May 1st

MISCELLANEOUS

AMERICAN PUBLIC HEALTH ASSOCIATION —The Fourteenth Annual Meeting of the American Public Health Association will be held at Toronto, Ont, October 5–8, 1886 The Executive Committee have selected the following topics for consideration at said meeting

1 The Disposal of the Refuse Matters of Cities and Towns

2 The condition of stored Water-supplies, and their relation to the Public Health

3 The Best Methods and the Apparatus Necessary for the Teaching of Hygiene in the Public Schools, as well as the Means for Securing Uniformity in such Instruction

4 Recent Sanitary Experiences in connection with the Exclusion and Suppression of Epidemic Disease

5 The Sanitary Conditions and Necessities of School-houses and School-life (See Lomb Prize Essays)

6 The Preventable Causes of Disease, Injury, and Death in American Manufactories and Workshops, and the best Means and Appliances for Preventing And avoiding them (See Lomb Prize Essays)

7 Plans for Dwelling houses (See Lomb Prize Essays)

All persons who propose to present papers at the next meeting of the Association will be governed by the following order, enacted by the Executive Committee at Washington, D C, Dec 7, 1885 "That all papers hereafter presented to the Association must be either printed, type written, or in a plain hand writing, and be in the hands of the Secretary at least twenty days prior to the annual meeting" This order will be strictly enforced, and no paper will be read at the said meeting that has not been received, examined, and approved by the Executive Committee Invitations extended to individuals to prepare papers for the Association do not imply their acceptance by the Committee, merit alone determining that question Papers that have been published will not be received

The Local Committee of Arrangements at Toronto, Ont, have already actively begun the work essential to a large and successful meeting In addition to the usual work incident to such an undertaking, they will extend invitations to foreign sanitarians, and secure such transportation facilities as will probably ensure a good representation from abroad Communications regarding matters of transportation or of a local character should be addressed to Peter H Bryce, M D, Chairman Local Committee of Arrangements, Toronto, Ont The cooperation of all persons interested in the public health, or in any subject allied to sanitary science, is respectfully solicited A circular giving full and concise information regarding local matters, programme, transportation, etc, will be issued in due season before the meeting

The Lomb Prize Essays —Mr Henry Lomb, of Rochester, N Y, who is already well known as a public benefactor through the prizes which he gave last year for the best essays on certain sanitary subject, offers for the present year the sum of $1750 to be awarded as prizes on the following subjects, as per conditions mentioned elsewhere

1 The Sanitary Conditions and Necessities of School Houses and School-Life   One Prize, $500

The object of the essays must be to furnish the most complete paper possible, embracing as far as may be all the details allied to the subject

Committee of Award—Dr E M Moore, President State Board of Health, Rochester, N Y , Medical Director Albert L Gihon, U S Navy, Major Charles Smart, Surgeon U S A , Prof C A Lindsley, Secretary State Board of Health, New Haven, Ct , Dr J T Reeve, Secretary State Board of Health, Appleton, Wis

2 The Preventable Causes of Disease, Injury, and Death in American Manufactories and Workshops, and the best Means and Appliances for Preventing and Avoiding them   One prize, $500

Under this head, the conditions and necessities of the American mechanic are to be especially considered, and the thorough consideration of a class will be regarded of more value by the judges than a superficial review of the whole field   Original investigations will weigh much in awarding the prizes, while compilations from existing literature or foreign statistics will not find favor with the Committee of Awards

Committee of Award—Dr Granville P Conn, President of State Board of Health, Concord, N H , Dr John Fallon, Member State Board of Health, Lunacy, and Charity, Lawrence, Mass , Dr Stephen Smith, New York City, Crosby Gray, Esq , Pittsburgh, Penn , Dr C W Chancellor, Secretary State Board of Health, Baltimore, Md

3 Plans for Dwelling-Houses

(a) A plan for a dwelling-house not to exceed in cost, exclusive of cellar, $800   Prizes   First, $200, second, $100, third, $50, fourth, $25

(b) A plan for a dwelling house not to exceed in cost, including the cellar, $1600   Prizes   First, $200, second, $100, third, $50, fourth, $25

Accommodations to be provided for families consisting of five persons

Committee of Award—Major John S Billings, LL D , U S A , Washington, D C , Col George E Waring, Jr , C E , Newport, R I , Dr E M Hunt, Secretary State Board of Health, Trenton, N J , Dr J H Raymond, Brooklyn, N Y , Prof Charles N Hewitt, Secretary State Board of Health, Red Wing, Minn

Specifications Regarding Plans for Dwelling-Houses—The features which will have especial weight with the committee of award will be   1 Ventilation   2 Drainage and other sanitary appointments   3 Convenience of arrangements   Each design to be represented by the following drawings

1 A plan of the principal story
2 A plan of second story (if present)
3 A longitudinal section
4 A front elevation and drawings of such details as may be required to illustrate any peculiar features of the design   The drawings are to be made all upon one sheet of paper, and comprised within a rectangle of 17½ by 24 inches

They are to be made at a uniform scale of four feet to the inch, except those representing details, and are to be made by lines, in India ink, without color or washes   Shading, if any is to be obtained by India ink lines

The drawings are to be accompanied by a concise, clear description of the arrangements and materials of construction, together with a detailed estimate of the cost of construction, which is to comprise Masonry work, Plastering, Iron work, Carpenter work, Roofing and Painting, Plumbing work, Sanitary appointments, and other required work and materials, and contingent expenses required to render the building ready for occupancy   The estimate to be given for each of the kinds of work above named, separately   The estimates to be made in good faith, from trustworthy data, and to be based upon the present market prices of material and labor in Albany, N Y   The prices made use of to be given in full detail to enable comparisons to be made for different localities, plumbing to be based upon the supposed use of pump, and estimate to cover so much of pipes and drains as will be within the walls

Object of this competition is to secure a general statement of the whole question of the best arrangements, both in economical and sanitary points of view, for housing the working classes

The name of the author of the design is not to appear upon the drawings, or upon anything accompanying them

Each drawing is to be marked with a selected word or sentence, used as a motto to distinguish the design from others   This motto, written on paper, together with the author's name, is to be enclosed within a sealed envelope, and this sealed envelope is to be enclosed within a second envelope, sealed and endorsed, with the word or motto, only, placed upon the drawing

Each design, together with the description and estimate, is to be enclosed within a tube of metal or very stout paper—the tube not less than two inches diameter—and sealed and forwarded to the Secretary

Conditions   All essays and plans for the above prizes must be in the hands of the Secretary, Dr Irving A Watson, Concord, N H , on or before Aug 15, 1886   Each essay must bear a motto, and have accompanying it a securely sealed envelope containing the author's name and address, with the same motto upon the outside of the envelope

After the prize essays and plans have been determined upon, the envelopes bearing the mottos corresponding to the prize essays or plans will be opened, and the awards made to the persons whose names are found within them   The remaining envelopes, unless the corresponding essays or plans are reclaimed by authors or their representatives within thirty days after publication of the awards, will be destroyed unopened by the Secretary

The Committees of Award are empowered to reject all papers and plans, if in their opinion none are worthy of a prize   The essays and plans awarded the prizes are to become the property of the American Public Health Association

None of the members of the Committees of Award will be allowed to compete for a prize on the subject upon which they are to pass judgment

The awards will be announced the first week in October, 1886, at the annual meeting of the American Public Health Association

It is intended that the above essays shall be essentially American in their character and application, and this will be considered by the judges as an especial merit

Competition is open to authors of any nationality, but all the papers must be in the English language

While the privileges of competing for the Lomb Prizes is open to all persons, it should be remembered that the highest standard of excellence will be required to win

Per order Executive Committee

Irving A Watson,
Secretary

National Sanitary Convention —A Sanitary Convention, the object of which will be to afford an opportunity for an expression of opinion on matters relating to the public health and the discussion of methods looking towards an advancement in the sanitary condition of the Commonwealth, the prevention of sickness and avoidable death, and the improvement of the conditions of living, will be held in Philadelphia, under the auspices of the State Board of Health, on Wednesday, Thursday, and Friday, May 12, 13, and 14, 1886

The following will be among the subjects that will be discussed by prominent Sanitarians 1 The Sanitary Needs of School Buildings and Grounds 2 The Water Supply of Towns and Cities 3 The Water Supply of Philadelphia 4 The Disposal of Slops, Garbage, Refuse, etc 5 The Prevention of Communicable Diseases 6 The Influence of Clothing on Health 7 Ventilation 8 The Drainage and Sewerage of Cities and Town 9 The Drainage and Sewerage of Philadelphia 10 The influence of Diet on Health 11 The Relations of Christianity to Health 12 Mistakes in School Architecture 13 Defective Vision in School Children Causes and Management 14 The Necessities of Physical Education 15 Drainage and Sewerage in Country Districts 16 Sanitary Science in Villages 17 Municipal Sanitation 18 Artificial Feeding of Infants 19 Condensed Milk 20 Various Artificial Baby Foods 21 The Inheritance of Disease 22 Hygiene of the Home 23 Sanitary Plumbing and Drainage 24 Tests for Impurities in Water The Use of Filters 25 Germicides 26 Vaccination 27 The Hygiene of Old Age 28 Cholera 29 City *versus* Country Life, from a hygienic point of view

The public are cordially invited to take part in and help to make a success of this Convention A circular of details will be issued at a later date

Joseph F Edwards, M D,
Chairman Committee of Arrangements
224 S 16th St, Philadelphia, Pa

The Association of American Medical Editors will meet in St Louis on Monday evening, May 3, time and place to be announced There will be a banquet, and each member is expected to contribute to the expenses

Medical Association of the District of Columbia —At a stated meeting of the Medical Association, District of Columbia, held on the 6th inst, the following were elected officers for the ensuing year

President—Dr J M Toner
First Vice-President—Dr J W Bulkley
Second Vice President—Dr Geo Byrd Harrison
Secretary—Dr Lachlan Tyler
Treasurer—Dr S S Adams

George N Powers, M D, has been appointed Professor of Ophthalmology and Otology in the Medical Department of the University of California, to fill the vacancy occasioned by the recent death of Professor A M Wilder, at San Francisco

New York State Medical Association—Fifth District Branch —The fourth special meeting of the Fifth District Branch will be held in Kingston, on Tuesday, June 15, 1886 All Fellows are cordially invited to contribute to the meeting, either by reading papers, notes or communications, or by exhibiting specimens The Secretary will be glad to receive the title of any proposed paper as early as convenient E H Squibb, M D *Sec'y*
P O Box 94, Brooklyn, N Y

Hæmorrhage after Uvulotomy —Dr E Carroll Morgan, 918 E St, N W, Washington, D C, wishes to collect recorded and unrecorded cases of this accident, in order to publish a monograph on the subject

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY FROM APRIL 10 1886 TO APRIL 16 1886

Capt J H Patzki, Asst Surgeon, relieved from duty at Jackson Bks, La, and ordered for duty as Post Surgeon at Mt Vernon Bks, Ala (S O 75, Dept East April 12, 1886)

Capt Jno Van R Hoff, Asst Surgeon, leave of absence extended for eleven months, with permission to leave the United States (S O 85, A G O, April 12, 1886)

Capt Richard Barnett, Asst Surgeon, granted leave of absence for two months (S O 16, Div Atlantic, April 12, 1886)

Capt H P Birmingham, Asst Surgeon (Camp Grant, New York City), temporarily assigned to duty at Ft Columbus, New York Harbor (S O 72, Dept East, April 8, 1886)

First Lieut Philip G Wales, Asst Surgeon, granted leave of absence for two months (S O 85, A G O, April 12, 1886)

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U S MARINE HOSPITAL SERVICE FOR THE THREE WEEKS ENDED APRIL 17 1886

Wyman, Walter, Surgeon, to represent the Service at the meeting of the American Medical Association, at St Louis, Mo April 12, 1886

Sawtelle, H W, Surgeon, detailed as chairman of Board for physical examination of officers of the Revenue Marine Service April 15, 1886

Urquhart, F M, Passed Asst Surgeon, relieved from duty at Norfolk, Va, May 1 1886, to assume charge of Cape Charles Quarantine April 16, 1886

Yemans, H W, Passed Asst Surgeon, detailed as recorder of Board for physical examination of officers of the Revenue Marine Service April 15, 1886

Heath, F C, Asst Surgeon, appointed an Asst Surgeon April 15, 1886 Assigned to duty at Chicago, Ill, April 16, 1886

THE DEMAND FOR MEDICALLY-EDUCATED WOMEN

The Doctorate Address delivered at the Commencement Exercises of the Woman's Medical College of Chicago, April 6, 1886

BY D W GRAHAM, M D,

PROFESSOR OF SURGERY IN THE WOMAN S MEDICAL COLLEGE, OF CHICAGO ILL.

Two years ago, at the graduating exercises of this college, our worthy President, Dr Byford, made an address in which he entered a strong and convincing plea for the fitness and capacity of women as practitioners of medicine He also pointed out how the changing conditions of our social fabric are constantly increasing the number of women who may and ought, for their own sakes to enter the medical profession

These considerations were made from what we may call the subjective standpoint—having reference largely to the interests and qualifications of individuals as candidates, or as possible candidates, for the honors and responsibilities of medical practitioners

But there is an objective side to the question of the medical education of women—having reference to the objects and aims of medical science and its place and power as one of the factors of civilized society Accepting it, then, as proved by argument and demonstrated by experience that women may and ought to enter the domain of medicine, we may ask what is the nature and scope of that domain? Is there in it a demand for her services, and what are the promises and opportunities for work and usefulness? Medicine means very much more in these latter days than healing the sick and attending to their immediate wants It had its origin in the simple desire to relieve human suffering, and for a long time was synonymous with the "healing art" But it has grown in scope and power with the ages, and it is especially within the last few decades that medical science has taken on new duties and new life, until it stands to day for the physical and moral perfection of the human race A recent writer (Dr A L Gihon) says It embraces all that relates to the existence of man, his place in nature, his origin, development and growth, his preservation and continuance,—the prevention and cure of disease being but a part thereof

Another writer (Sir Henry Acland) says Whatever be the duty of individuals, medical art and science collectively now aim as a whole, 1st At the preservation of health 2d At the averting of disease from individuals and from nations 3d At rearing healthy progeny for the family and the State by probing the laws of inheritance, and 4th Procuring legislation effectual to these ends It claims, therefore, a voice in moral education as well as physical training, it holds a duty in relation to the diminution of vice for the sake not only of its self destroying victims, but more for the sake of the innocents whom they ignorantly slay

It is often claimed for the medical profession, both by its own members and others, that its chief glory is its charity But its greater glory is the record of its effort and its interest in the prevention of disease The brightest page of its history, and that which covers a multitude of its sins, is that in which it recognizes that the preservation of human health is a privilege and an obligation no less sacred than the restoration of health

The medical profession, as a constituent class of the community, has no more interest in preventing or mitigating the ravages of epidemics, or the spread of communicable diseases, or in analyzing and studying the conditions of our individual and associated environment to discover which promote health and which give rise to disease, than has any other class And as practicing physicians, all their efforts in this direction would be suicidal from a business point of view, and in every way detrimental to their own best interests, if they are to be measured by the standard of the average judgment of the public and the public press

Yet we find that the members of the medical profession are almost the only members of society who have an active and an abiding interest in preventive medicine They almost stand alone as contributors to the sum of knowledge which makes up sanitary science

They are always the leaders and the most zealous workers in those organizations whose objects are to teach and to preach hygiene and health to the community, or to prepare the way for and urge correct sanitary legislation It is difficult for the public to realize or to estimate rightly the value of what has been accomplished for humanity in this direction

The devastating epidemics of former generations have been suppressed, and their ravages mitigated. It is possible to eradicate such a disease as small pox [illegible] that every man, woman and [illegible] in accordance with the established [illegible]

The list of preventible disease is constantly increasing, and the means and methods of preventing them are being better understood We know better than ever before, as individuals what to do, where to go and how to act, that we may avoid disease and preserve health

But the work in this broad field has only just begun It is along this line that medical science is yet to win its best victories New facts are to be discovered, new principles established, new problems solved and new methods elaborated But in order to make these facts and discoveries available and effective, a knowledge of them must be diffused among the people and if the sanitary science of the future is to demand of the law maker such laws as will give the people the three pure requisites—pure air, pure water, and pure food—to quote a prominent sanitary writer, then that law maker must be one who knows what constitutes purity and something of the best methods of securing it

Medical science has both a duty and a privilege in relation to the defective and the helpless classes of society Together these form a considerable percentage of the population One of the marks of civilization, and, at the same time an index of the degree thereof, is the care bestowed on these unfortunate classes In barbarous tribes they are either killed outright or conveniently allowed to die, in the same way, and for the same reason that the female children are disposed of—they eat but cannot fight, and hence are an incumbrance to be got rid of The deaf and dumb, the blind, and the feeble minded have claims and rights which civilized communities recognize They have not only a right to live, but a right to a higher life than simple animal existence They have a right to be made useful—a right to that kind of treatment and training which will compensate as far as may be for their natural defects It belongs to medical science to discover the underlying physiological and pathological conditions of these defects, and to point out and apply the most effectual methods of securing the desired results It is to the honor and the credit of the medical profession that they have ever been foremost in this truly philanthropic work

Then, of what are called the helpless classes, take, for example, the incurable insane—a large and an increasing class Society does not come up to the full measure of its duty towards these unfortunates In many communities they are treated less humanely and with less consideration than if they were criminals Right here, in our own city, enough facts could be collected in twenty-four hours by anyone which, if plainly stated, would be a revelation to nine tenths of our citizens, and a cause of shame to us all And if we consider the facts as they exist, especially in relation to the pauper insane, throughout the whole country, it would be a dark page of civilization The medical profession [illegible] ble for this state of things, knowing it not They have a right, by virtue of their knowledge and their calling, to insist upon and demand better laws, better management, and better public provision for the chronic insane

Again, there are great problems concerning the criminal class which no one is so well qualified to study and solve as the medically educated man or woman It is questionable whether the prevailing methods of dealing with criminals do not cause more crime than they prevent Formerly much more than now, but even now, the spirit of our criminal laws and the method of enforcing their penalties is largely the spirit of retaliation It is a well recognized fact that some individuals are born with moral defects as others are born with physical defects The actions of a man who is born blind or is color blind are judged of differently from those of other people Should a man who has analagous congenital moral defects be judged as other men are judged? In China, when a man has committed a capital crime, a minute inquiry is first made into his physical condition, his temperament, his mental complexion, his prior acts, nor does the investigation stop at the individual—it is concerned with the most inconsiderable antecedents of the members of his family, and is even carried back to his ancestry While the Japanese laws, it is said, include the parents of the criminal in the punishment (Ribot, "Heredity")

Then there are moral defects and deformities due to the education and environments of the plastic period of youth, just as there are acquired physical deformities For instance, take the foot of the the Chinese woman, which has been arrested in its growth and distorted into an unrecognizable mass by the systematic *training* applied to it from youth up We do not expect such a person to walk with the same ease and grace and equilibrium as one whose feet have normal power and development Why, then, should we expect one whose mental and moral faculties have been similarly stunted and distorted to have the same rectitude of purpose and conduct as one whose faculties have been trained into full and normal development

When facts like these are fully developed and recognized, our management of criminals will be more discriminating, more rational, and more productive of results, and while not holding the criminal guiltless of his crime, our laws will take cognizance of the fact that there is guilt somewhere outside of the individual himself, and a corresponding responsibility

Then there are the facts and the laws of heredity, as yet almost an unknown quantity What are they and what is their import? How and to what extent may a knowledge of them be made available for the benefit of the race or the individual? What do we get by inheritance from our ancestors in physical characteristics, in intellectual traits, in moral tendencies It is an established fact, as an authority (Ribot) says, that heredity tends to transmit to the descendants the whole nature of their parents, as well every physical, mental, and moral deterioration, as every physical, mental and moral ameliora tion. But we know little about the laws of inheritance, and still less about how they may be utilized. These are great questions, and have an important bearing on all that pertains to human progress. They especially concern the physician in his efforts to prevent and control disease, and their study and solution are peculiarly within the domain of medicine.

Medical science also claims the right to speak in all matters of education—not only to advise and supervise, but to dictate. Here, if anywhere, medicine should exercise the right of eminent domain. Education and heredity are correlative factors. Together they determine whether the individual shall be good or bad—a useful or dangerous member of society. No educational theory is correct unless these facts are duly recognized.

It is only within recent years that physical training has anywhere received proper practical recognition as one of the elements of a complete education. More generally it is practically ignored, or assigned a very subordinate place in our educational institutions. More especially has this feature been neglected in the education of our girls. But there is evidence of a growing interest in this direction. An association of National character has for one of its chief objects the promotion of the physical education of women. In a recent report they realize that the physical status of American women of the educated class is painfully low, and urge measures against this dangerous deterioration of physique.

In all these directions I have pointed out, and in many others of a similar nature, there is a positive demand for the services of the medically educated woman. Here are opportunities enough and scope enough for all shades of tastes and all degrees of talent. Women are peculiarly adapted for much of this kind of work. The thousands of women of our land without occupation, with physical and mental capacity for a long life of usefulness, with noble and philanthropic aspirations, will find in these fields abundant work which will yield the most beneficent and tangible results.

A medical education is not a pre-requisite for all those who may devote themselves to these lines of work and study, but more or less knowledge of medical science and its fruits is necessary for all. But there is no better preparation for and no better stimulus to pursue such an occupation than a thorough medical education. Even as a means of individual education the study of medicine, I believe, ought to have a place for the women who expect to spend their lives in the relations of home and family exclusively. With some modifications a three years' study of medicine would be of more benefit to any woman in the way of mental discipline, combined with acquisition of useful knowledge, than a three years' course of study in most of our popular seminaries. The purely ornamental in the education of women, I think all will agree, has been overdone. A young architect once presented a specimen of his work to his senior for criticism. The criticism was the injunction: "Ornament construction instead of constructing ornament." There is much in refined society that reminds one of this criticism, so out of proportion are the simply ornamental accomplishments. But it will continue to be as heretofore, that the great majority of those who study medicine will expect to practice medicine.

We hear much in these days about the overcrowded condition of the medical profession. It is a favorite theme of discourse both in public and private and on many occasions. It may be fairly doubted, however, whether these complaints are just and in accordance with the facts when we look at the question in comparison with other professions and occupations where special and superior knowledge and training are required. They are all crowded, and probably in about the same degree. Inquiry will show no vacant place, no encouragement for the new recruit, the supply being already greater than the demand in all of them. Close and never failing competition is the rule in all trades and professions. The young woman, as the young man, looking for an occupation, who accepts the surface indications of supply and demand, will never find a place that is not preëmpted and occupied, and may just as well surrender before beginning the battle. It is often stated that the ratio of practicing physicians to the population is steadily increasing, and that there are more physicians to a given number of people in this country than any other. Both of these statements are probably correct, but they prove nothing against the claim I am now making, viz.: that the medical profession is relatively not more crowded than other lines of desirable and useful occupations. Moreover, the purely numerical standard is misleading. There are other factors that enter into the question which it is not necessary to point out here.

And while it would probably be difficult to find any community in this country where there is an apparent need of more physicians, and while it is true, as is claimed, that the standard of requirement for admission to the ranks of the profession is not as high as the present conditions of things demand, yet when all is said and everything admitted, it still remains a fact that to-day the practice of medicine in this country offers as good prospects and opportunities to the man or woman of average intellectual capacity and good training as can be found anywhere, both for earning a good living and for a life of the highest usefulness. There is room and even demand for the thoroughly earnest, well educated medical woman in almost all parts of our country. But it is outside of our own country that the American medical woman will find the great opportunities and an unlimited demand for her services as a practitioner of medicine.

The oriental countries contain about 800 millions of people—fully one half of the population of the globe. The low estate of the women of these countries has been portrayed many times. The story of their physical, mental and moral condition sounds to us like a fable. A writer says:[1] "The women of America do not generally understand how degraded their oriental sisters are, and even travellers who have the very best opportunities for observation cannot appreciate their real condition. If we except

---

[1] Houghton. Women of the Orient.

Japan, it may be truthfully said that throughout the Orient a girl is regarded by the entire household both as an intrusion and a calamity, and the prevailing estimate of the female sex is most degrading and brutish. In Mohammedan countries at least, a man makes a profound apology whenever he deems it necessary to speak to another man of either a dog, a hog, a donkey or a woman. The Japanese, although more liberal in their treatment of woman than other Eastern nations, habitually look upon her as a portion of creation whose only use is to perpetuate her species and minister to man's pleasure and comfort. Practically she is recognized only as a slave, and whether in the palace of a prince or the hut of a beggar she is systematically condemned to moral and physical degradation, In China, also, the idea that woman exists only for the convenience of man, and scarcely shares the same nature, is thoroughly fixed in the national mind, while with the Hindoos, both by sacred law and custom, she is consigned to a degradation which is without a parallel in the history of our race. In every particular the Eastern idea of woman is debasing and unworthy.

While this state of things is well known in a general way by all Christendom, yet I think there are very few who actually realize that this is not an exaggerated picture of the condition of more than half the women of the whole world. The science of medicine as we know it has no existence among the oriental people. They have no knowledge of the structure or functions of the human body nor of the true nature of disease. "Charms, superstitious rites, barbarous treatment, vile medicine and foolish religious ceremonies are the unavoidable accessories of the sick room, and frequently induce a fatal termination which nature, if left to herself, would have averted." In all [illegible]cept the few localities where European civilization [illegible]s penetrated they are practically without medical treatment. And the women are deprived of even these slight advantages owing to the seclusion which the inflexible religious and social customs impose. So that educated female physicians can find in this vast region a special field for their services, where there is no competition and the demand is greater than the supply. Experience shows that the direct benefits to these women of rational medical treatment are incalculable. But it is as pioneers and forerunners of a Christian civilization that these medical women are to carry the greatest blessings to their degraded sisters. A great responsibility is upon the women of America. The opportunities and the possibilities are infinite.

Speaking now more directly to the graduating class, I extend to you in the name of the Faculty a cordial welcome to the ranks of the medical profession. You have passed the arbitrary line which technically separates the student from the physician. You will realize that in one sense this line is only an imaginary one, such as astronomers use for the purposes of reckoning. But still to all who pass that line, as you do to day, there come new privileges and new duties. If you would enjoy the one you must fulfil the other. If you would catch the spirit of duty you must align yourself with the true workers and representatives of the profession. General Sherman in his memoirs makes the observation that the rear of an army in action is not the place from which to judge of success at the front. On approaching from the rear one would conclude that defeat and disaster had overtaken the whole army, while at the front there would be nothing but victory.

So it is in the medical profession. The truly representative members, those who work and win the victories for medical science and humanity, are like the stalwarts in the front of the army who in their strength and prowess are steadily and surely advancing and rejoicing in their triumphs, and also, like the fighting part of the army, they are mostly out of sight of the public eye and out of hearing of the public ear. But in the rear are the laggards, the croakers, the cowards, the spoil seekers and the prophets of evil. These seek and obtain the public ear, and hence it is that the public so often fail to discriminate between, for instance, the spoil seekers or the croakers and the honest and faithful workers. Hence it is, also, that so often in our current literature and the public press the medical character is a weakling or a medical monstrosity, and that the spirit and status of the rear of the medical army are reflected rather than those of the front.

The most comprehensive advice I can give you to day as new recruits is to face to the front and place yourself immediately in the ranks side by side with the faithful veterans. Thus you will never be troubled about individual duty, and need give yourselves no concern about the rewards and honors, for these will come spontaneously.

Accepting the badge of admission to the medical profession as you do to day intrusts you with a share of responsibility for the honor and good name of the profession, and implies a tacit acceptance by you of this trust. The temptations for the physician to violate this trust, to turn aside into devious ways for selfish ends, to subordinate the professional to the trade spirit, and to make commerce of the sacred relation of physician and patient, are many, and not a few find them irresistible. The condition and fate of such are somewhat as when centuries ago, in one of the Netherland provinces, a free woman who intermarried with a slave condemned herself and offspring to perpetual bondage and disgrace. But she had an alternative. She was girt about with a sword and a distaff. Choosing the one she was to strike her husband dead, choosing the other she adopted the symbol of slavery and became a chattel for life.

OVARIAN EPILEPSY, FOUR CASES

A Clinical Lecture delivered in the Gynecological Clinic of the Medical College of Ohio,

BY C. D. PALMER, M.D.,
PROFESSOR OF GYNECOLOGY IN THE COLLEGE.

The first case to day, gentlemen, is that of Mrs. Mary C., aged 29 years. She has been married nine years, and has had two children, the youngest being now four years old. The patient is a bleacher in a laundry, in which she has worked for eighteen months

Her occupation requires her to remain standing while at work

She has been having fainting spells once a day, more severe at the menstrual epochs These fainting spells came on after she began work in her present position The menstrual flow occurs once a month, and lasts two days She has backache and is constipated The left ovary is prolapsed, and there is slight retro version and congestion of the uterus

The diagnosis in this case is epilepsy, *petit mal*, occurring more frequently at the menstrual periods, and aggravated by the patient's occupation She has been under treatment for three months, on pil podophyllin for the constipated condition, and bromide of potassium for the epilepsy Under this treatment there has been marked improvement

The second case is that of Mrs A K , a widow, aged 43, who has had one child Her menstrual flow is regular, lasting four or five days It is not accompanied by pain, and is rather scant There is a condition of slight leucorrhœa, and she complains of backache and constipation She has had periodical attacks of unconsciousness and convulsions at the menstrual period for eight years, especially during the past two years Occasionally, say each third time, the attacks intermit, but sometimes she has attacks in the intervals

Physical examination shows that the uterus is low, slightly retroverted, and congested There is no laceration of the cervix

The malady was diagnosticated as menstrual epilepsy, and on treatment with bromide of potassium, three times a day, and Hunyadi Janos water or rhubarb for the condition of the bowels, she has improved in general health

The third case is that of Miss A , 15 years of age, who was admitted to the Hospital on September 1, 1885 She has had epileptic attacks for the past fifteen months She has not menstruated, but it is probable that ovulation has taken place The attacks come on regularly once every month You can see that she is small and but illy developed Like the other patients shown you to day, she is very constipated

On the diagnosis of ovarian epilepsy she will be put on bromide of potassium, gr xv three times a day, and pil podophyllin It is necessary that she have good food, exercise, moral and mental training, and vegetable and chalybeate tonics We give bromide of potassium to this class of patients because it has a sedative influence on the nervous system, and on the sexual organs at the menstrual period This patient should have physical employment, not severe, and should get out into the fresh air every day We may say that the diagnosis in this case is favorable for cure It is probable that the uterus of this patient is as ill developed as her body, and her menses will probably come on later It is one of the cases in which mothers resort to hip baths, hellebore, savin, rue, etc , a very pernicious method of treatment We may as well try to get a girl five or six years old to menstruate The salient features of the case are that the girl has had attacks every four weeks, probably at the time of ovulation Why does she have epilepsy? Probably she has no organic disease of the nervous system, and if brought to view probably no structural changes could be found There is probably some defect in the hemispheres, she has a very mobile nervous system

When examined on December 7, three months after admission, she had had no attack for three months Previous to this the last two attacks were two months apart, but occurred at the time of her menses On December 25 she began to celebrate Christmas in the usual manner, with candy, nuts, etc , and contracted a cold On the next day she had an attack, the first for sixteen weeks She has been under treatment now for five months and a half, on the bromide of potassium, and has had no attack since the one at Christmas This treatment will be continued for a year or two, even if there be no recurrence of the attacks, simply as a preventive measure As shown by her experience at Christmas, errors in diet may render futile all the good accomplished by months of treatment

The fourth case is that of Miss L , of American parentage, unmarried, 27 years old She entered the Clinic in the spring of 1883, and stated that for nine years previously, that is, since the first appearance of the menses, she has suffered from epileptiform attacks They usually occurred in the day time, seldom at night, and were accompanied by loss of consciousness Prodromata were always present, in the form of headache, general nervousness, and pain in the left ovarian region and the left arm, all aggravated by errors in diet After their first appearance the menses ceased, but the attacks occurred monthly, and she was never regular in menstruating until the year before she was admitted to the Clinic For a short time, too, she had intermenstrual attacks

On admission her general health was fairly good, the menses regular, of normal quantity, and lasting four days, though there was some dysmenorrhœa Physical examination showed nothing markedly abnormal, except tenderness in the posterior lip and the left ovarian region

On the diagnosis of *petit mal* of ovarian origin, she was put on regulated diet, with Fowler's solution for the stomach trouble, and a teaspoonful three times a day of a solution of bromide of potassium (ʒss—water ℥ij) Tincture of iodine was applied locally in the ovarian region, and later the emplastrum cantharidis over the ovaries a few days before the time for menstruation This treatment was continued for a considerable length of time with very marked improvement Up to April 19, 1885, she had had four attacks, on April 25 she had another, and three more by May 24 On May 31, 1884, it was noted that she had had only two attacks since Christmas She attended the Clinic irregularly, but bought the bromide by the pound and took it regularly at home In the autumn of 1885 she began to take gr xxx dissolved in half a glass of water three times a day

In this case improvement followed almost immediately on the commencement of treatment, that is, within six or seven weeks Treatment was then suspended and the attacks recurred It was renewed, and the attacks became much less severe, and diminished to two in a month It does not at all follow that there is much local pelvic disease to produce this form of epilepsy In some cases the attacks occur only at certain menstrual periods at first, and after a few years they come on more frequently and with more severity, and between the menstrual periods This often occurs in patients who are irregular in menstruating It is difficult to say just what pathological lesions are present in these cases Many of these cases occur in persons who are illy developed as regards their nervous systems They need improved hygienic surroundings, good food, and evenness of life They should not be idle, but the occupation should not be arduous If young, great attention should be given to proper schooling of the mind, so that it may be better developed, when it is less liable to disturbances Mental shock, moral disturbances, indigestion, worms, ovulation, etc , may disturb the nervous system sufficiently to cause these attacks It is probable that this patient masturbates Patients who have migraine often escape epilepsy, and *vice versa* If you can carry the patient over one attack it is a great gain for the nervous system, as every attack weakens, and increases the liability to others Finally, for these cases the ovaries may be removed, but this should be done only as a *dernier ressort*

BORACINE

BY W THORNTON PARKER, M D ,

OF NEWPORT R I

The earliest of medical writers knew of the antiseptic qualities of boric acid, and its healing and purifying properties have been recognized for centuries It has been recommended for use in solution, in powder and in ointment for the treatment of wounds, burns, and sores of all kinds, and yet when the dangerous properties of carbolic acid, iodoform, and the bichloride solution had been proved over and over again, and no satisfactory substitute discovered, borax still remained in great obscurity Although its value was known so well, yet it was not considered worthy of rank as an antiseptic, and few believed that it possessed germicide properties

The writer first became interested in the subject of antiseptics while attending the surgical clinics of Prof Lister, in Edinburgh, in 1870, and subsequently in the Continental hospitals opportunities were afforded for witnessing the effects of carbolic acid, salicylic acid, iodoform, bichloride solution, etc In the hospitals of Bonn, Leipzig, Vienna, Freiburg, Tubingen, Munich, Heidelberg, Wurzburg, Paris, London and Dublin, I watched the development of the antiseptic method for surgery which Lister had so brilliantly brought forward Each hospital had its individual procedure for the protection of wounds The Charing Cross Hospital, London, in 1882, had developed the value of boric acid in combination with glycerine and since that time to the present the writer has found no preparation more satisfactory for antiseptic purposes than that now manufactured by Theodore Metcalf & Co , of Boston, viz boracine

Boracine is composed of boric acid, glycerine, menthyl salicylate, menthol, thymol and eucalyptol For surgical purposes it is best prescribed in solution, one part of boracine to twenty or thirty of water It can be used, however, from 10 per cent to 50 per cent in strength as may be indicated Under its use wounds of all kinds heal as rapidly and as satisfactorily as under carbolic acid dressings, but with boracine there is no danger from poisoning, and the wound and the surrounding tissues are not inflamed or injured It is, in fact, entirely innocuous when applied to a wounded surface For minor surgery it is useful as an ointment combined with cosmoline, vaseline, or lanolin, the new basis for ointments

℞	Boracine	℥iss
	Adips	℥ij
	Lanolin	℥iv

M

Boracine is useful as an application in chronic otorrhœa, in diseases of the nasal passages, chronic catarrh, etc , and for diseases of the rectum I have found it very useful as an application for chronic cases of pruritus ani, as well as in general cases of prurigo In such cases it will often afford perfect relief where other remedies have failed For the treatment of ulcers of the leg nothing could be more satisfactory It should be used as a thick paste completely covering the sore I direct the patient to carefully and thoroughly wash the ulcer and the surrounding skin with the best Castile soap, then apply the pure boracine, and then to bandage the leg with the solid rubber bandage

For injection in cystitis it is to be highly recommended For use in diseases of the eye it is excellent For the treatment of diphtheria in 25 per cent solution for the steam atomizer I have found it excellent, and altogether preferable to any other preparation known to me For an injection in the puerperal state nothing could be better than a 25 per cent solution of boracine This can be used with safety, while other preparations like carbolic acid have often proved injurious and even dangerous In gynecology it is especially useful in solution as an injection for leucorrhœa, vaginitis, etc It is an excellent application for ulcerated cervix, spread thickly on the diseased surface It can also be spread on absorbent cotton and introduced and applied in that manner After considerable experience with the various preparations used for local treatment in these disorders, I find none yielding such satisfactory results as the boracine The cleanliness and the gentleness of this remedy, and the steady improvement resulting from its use, will be very satisfactory to both patient and physician

Messrs Metcalf & Co have, at my suggestion, made vaginal and rectal suppositories of boracine in combination with gelatin, and pencils of the same for intra uterine and other uses These contain 25 per cent of boracine The suppositories are of three sizes—Nos 1, 2, 3 No 1, the smaller, is a useful suppository in various rectal disorders, particularly in piles, and I have also used them with great success in the treatment of "thread worms" No 2 is of medium size, and can be used either for the rectum or for the vagina Where a larger amount of boracine is required, in cases of chronic leucorrhœa, vaginitis, or uterine disease, No 3 suppository is indicated The larger suppositories should not be used more than three nights in succession, and experience has taught me that the best results are obtained usually by using them every other night

In chronic eczema of the scalp I have found the action of boracine remarkably good Cases which have refused to improve under ordinary treatment respond quickly to the use of boracine ointment I direct the head to be shaved and carefully washed with Castile soap, and boracine ointment, 15 to 20 per cent, applied The washing with Castile soap and careful drying is to be attended to night and morning, and then the ointment is applied with the most satisfactory results In many obstinate diseases of the skin boracine will be found very valuable

So many new antiseptics have come into notice of late that boracine will be viewed with some doubt, but the writer feels confident that the experience he has had with the new antiseptic justifies him in praising its merits and in cordially recommending it for use by the medical profession To say the least, we have no antiseptic better at hand at present, and, in the writer's opinion, nothing which can equal it in general usefulness

Newport, R I, April, 1886

MEDICAL PROGRESS.

THE ANTISEPTIC TREATMENT OF WOUNDS —At the close of an interesting article on this subject SURGEON-MAJOR W GRAY calls attention to the fact that in a long series of cases the latter half were much more successful and this greater success appears to coincide substantially with the disuse of the waterproof covering, and with the adoption of dryer and thicker absorbent dressing Accurate adaptation of the flaps I regard as of great importance I now always mark them out with a scalpel, in order to insure evenly cut edges, and when the skin has contracted they are completed by transfixion in the usual way My experience has taught me, too, that antiseptic applications direct to the wound are in many cases unnecessary I allude especially to those cases where the tissues are perfectly healthy Still they do no harm, and, by way of making "assurance doubly sure," may be employed in every instance All I mean to convey, however, is that we can in a certain class of cases obtain as good results without as with them, provided we attend carefully to other precautions I never under any circumstances use the spray Moisture in any shape or form I look upon as one of the most fertile sources of failure Our whole efforts should be directed to preserve both the wound and the dressing in the driest condition possible The essentials, then, of my present procedure are cleanliness, infrequent dry dressing, free drainage, accurate adaptation of flaps, and rest Under the last mentioned, pressure by means of bandages may be included To prevent putrefaction of bloody and serous discharge I prefer to have the dressing medicated with some unirritating stable material Of all I have tried, boracic acid or iodoform is decidedly the best The latter is more expensive, however, hence I have found boric cotton more convenient to use In order to press the flaps close together, and thus lessen or avoid exudation, I draw the bandage as tight as possible, the thick elastic pad of cotton and oakum underneath will always prevent it being drawn too tight So effectually does this answer its purpose that I have on more than one occasion found the original dressing, on first exposing the stump, almost perfectly dry and clean Oakum, besides being more or less antiseptic, keeps the cotton together, and enables us to save the use of the latter to a certain extent as well Wood-wool, although a most excellent absorbent dressing in suitable cases, is somewhat unmanageable in amputations Made into pads, it does not fit closely enough, and employed loose, it is difficult to apply, and is inclined to get lumpy or become displaced To ensure complete rest of the parts while the healing process goes on, the limb, if it be a lower one, is fixed in a heavy box splint and well packed round with cotton Should the upper limb be operated on, the stump is securely fastened to the side of the trunk, with plenty of cotton interposed and placed around The cotton packing, as well as the thick dry dressing, preserves the normal heat of the parts, a matter which I believe is essential to rapid and perfect union Lowering of the temperature by wet dressing, exposure, or cold applications tends, I am convinced, to delay or prevent union by first intention During the progress of the case the thermometer is used morning and evening, if the temperature remains normal, or does not rise beyond 99 5° F occasionally, all is going on well, and the original dressing need not be disturbed sooner than the ninth or tenth day When removed the flaps will be found firmly united The drainage tube may now be withdrawn, its track gently syringed out with carbolic or sublimate lotion, a little iodoform introduced, and the stump redressed with oiled lint or with boric cotton, taking care to sprinkle either with iodoform Some of the unsoiled boric cotton from the original dressing will do quite well enough A pad of oakum and a bandage complete the second dressing This may remain on for four or five days longer, and when removed the track of the drainage-tube will have closed The sutures may now be taken out, the stump being practically healed Should the temperature, during the course of the second or third day, rise to 100° or beyond, and remain so, the antiseptic dressing has probably failed and must be removed, the stump being treated in the ordinary way, or, better still, with wood-wool and iodoform Before doing this I always administer quinine, as the fever may be of malarial origin, and not traumatic In more than one instance this has proved to be the case The precaution I note here is, however, scarcely necessary, except in a climate where malaria prevails

This paper has run on to such a length that I can hardly do more than to mention that the treatment, on the same principles, of other surgical and of accidental wounds has met with nearly equal success. In the former class of cases, especially where there is much areolar tissue—say, the axilla after removal of a large tumor—the surface, after bleeding has quite ceased, is well rubbed over with iodoform, closed, and dressed with boric cotton and oakum, as described above, and the result is all that can be desired. In the operation for the radical cure of hernia, or after herniotomy, this treatment of the wound has been attended with remarkable success, union by first intention being the rule. Accidental lacerated and incised wounds are first thoroughly cleansed with carbolic lotion, then washed with sublimate lotion, iodoform is rubbed in, and the dry dressing, either boric cotton or wood wool, applied. Sutures are not used, no matter how widely the wound may gape. The first dressing may be left on for twelve or fifteen days, or even longer, provided the temperature keeps down. In compound fractures the preliminary cleansing must be very carefully done before the sublimate lotion and iodoform are applied. The latter lotion should be forcibly injected with a syringe into every crevice of the wound. I find that for this purpose a Higginson's enema syringe is the most convenient, a continuous stream of lotion may be easily sent by it up the sheath of a tendon or, in case of amputations, between the flaps after the sutures have been inserted. The dry dressing in compound fractures requires to be very thick and to be bound on firmly, the limb is afterwards fixed on the appropriate splint. Small or clean cut wounds under this method of treatment will be found closed on removal of the dressing, and larger ones with a healthy granulating surface.—*Lancet*, April 3, 1886.

TREATMENT OF HÆMOPTYSIS.—MR. H. T. BACHELOR, of Queenstown, Cape Colony, says: In considering the treatment of hæmoptysis, one naturally looks for the cause, but I think in the cause ought to be included the liability to bleed in the individual, that is, the constitutional liability, as well as the reason why he bleeds from the lungs. Bleeding is by no means an unfamiliar accident to which mankind is liable, but if we could select our bleeding ground, it would not be the lungs. But bleeding in itself ought to be regarded chiefly as an expression of a diathesis, whether it comes from the nose, lungs, stomach, rectum, kidneys, or uterus, an expression of a diathesis aggravated probably by some error in diet or other temporary cause. I am not now referring to bleeding from ulcerated lungs or stomachs, etc., where a vessel is opened, and the treatment would best be met by a ligature if we could only apply it, but to the hæmorrhage which occurs suddenly in a person in good health, and from an apparently healthy mucous membrane. The diathesis which underlies the tendency to bleed has, by Mr. Jonathan Hutchinson, been shown to be the gouty. Fothergill's definition of gout is: "Gout is hepatic reversion—the formation of primitive urine products by a mammalian liver." If these two statements be accepted as correct, it follows that bleeding is due to functional derangement of the liver, or to put it differently, dissolution from its normal and healthy development or imperfect evolution.

Now, I firmly believe that the tendency to bleed occurs with the gouty diathesis, and that the excess of uric acid in the blood, and the locality of the bleeding, is due to individual peculiarities. Most people in youth inheriting this diathesis bleed from the nose, later in life, from the rectum or uterus, some of them from the lungs. Now, those who do so from the lungs need not necessarily descend from phthisical ancestors, a badly formed thorax, interfering with due expansion of the lungs, may be a sufficient cause. But, apart from such considerations, and to come to treatment, I think such people are best cared for by being dieted. Alcohol and meat are pernicious. But, supposing such a person has an hæmoptysis, saline purgatives, diuretics, and diaphoretics will best meet the case. But as these people are always very nervous, it is necessary to administer a nervine tonic. Opium may also be given, cannabis Indica is almost better. I quite agree with Dr. Samuel West in his remarks on profuse hæmoptysis published in the *British Medical Journal* of January 16, 1886.

It is to my mind often amusing to read the experience of some as to the value of a particular remedy in the treatment of bleeding. It seems to be forgotten that bleeding naturally ceases when the vascular system is adequately reduced. This is nature's method of saving the patient, and we cannot do better than imitate her. Bleeding, therefore, or dry cupping, or depressants, ought to be effectual aids as applied by us. Certainly, astringents imbibed cannot hold out much prospect of doing good. And as iron and opium also do not agree with these gouty people if continuously used, much care ought to be exercised in prescribing them.

Iron and digitalis I believe to be a particularly obnoxious combination. A man has an hæmoptysis, we will say, and he is given such a mixture. It is supposed that it stops the bleeding, whereas I believe the bleeding has stopped naturally. He continues with the mixture to prevent a recurrence, with frequently unhappy results. The iron impedes still more the already imperfectly acting liver, and the digitalis increases the tension in the already wounded vessel. It follows, then, that a recurrence may be naturally expected. Then, as to the bleeding from the lungs, the danger does not lie in the amount lost, but in the irritative changes it induces in the lung substance. Now, it is believed that the cough must be allayed (and to do this, opium is usually given) in order to prevent more bleeding. If it be accepted as true that the bleeding naturally tends to cease, I think we ought not to do anything to interfere with the expectoration of the effused blood. I am certainly of opinion that, if it be necessary to give opium continuously, in order to stop more bleeding, although the patient may not die of hæmoptysis, he assuredly will eventually of lung inflammation. To give opium is assuredly a barbarous way of treating lung affections. In order to explain an apparent discrepancy with a former statement, when I said that opium might be given to allay the vascular and nervous tumult, I wish to say that a single dose may be given for this object, but the continuous administration is hurtful. As I said before, I believe cannabis Indica the better of the two for this purpose. —*British Medical Journal*, April 10, 1886.

PYRIDINE IN ASTHMA.—PROFESSOR SEE, in a lengthy article (*Bull. Gen. de Therap.*, Oct. 1885) upon the treatment of the various forms of asthma, makes the following remarks upon pyridine in the treatment of that disease. When the iodides can not be taken, or when they give rise to grave symptoms of iodism, the patient usually resorts to some empirical remedy in the form of an inhalation. An analysis of this usually shows it to contain pyridine as the active ingredient. Pyridine is the product of dry distillation of pit-coal, and is a liquid, colorless, very volatile, and has a strong and penetrating odor. It is miscible with water in all proportions, forming with the mineral acids soluble but unstable bases. It diminishes the reflex functions of the medulla and respiratory center.

The best way of administering it is to put ʒj to ʒj mxv in a saucer, and place the saucer in the center of a small room, the patient to sit in one corner of the room, so that, as he breathes, he inhales an air mingled with pyridine. The *seance* should last from twenty to thirty minutes and be repeated three times a day. The absorption is rapid, for it soon appears in the urine. Great relief is experienced in a short time. Occasionally, toward the end of the sitting, the patients have an invincible tendency to go to sleep. In some cases the attacks of asthma had entirely disappeared; in others they returned in eight or ten days. The following is an analysis of Professor See's experience with the drug. Of fourteen patients (three females and eleven males, from 30 to 60 years of age), three suffered from pure neurotic asthma, and were cured; three, with catarrhal and emphysematous asthma, received amelioration; in one old case of nervous asthma there was benefit, but the drug had to be suspended on account of the vertigo and nausea it caused; in five cases of cardiac asthma the amelioration was pronounced without any ill effects upon the heart. In a subsequent note Professor Sée adds: During the past three months I have used pyridine inhalations in about fifty cases, in most of which the patients not only received relief during their attacks, but were cured without the intervention of potassium iodide. I am therefore, constrained to consider pyridine no longer as a simple palliative, like the fumes of niter, but as a true curative remedy, and one entirely free from all inconveniences.

Dr. Lublinski's communication (*Centbl. fur die Ges. Ther.*, Heft xii, 1885), embodying his experience with pyridine in asthma, is of considerable interest and value taken in connection with the foregoing abstract of Professor Sée's paper. He does not undervalue the importance of treating the nasal passages, and the administration of potassium iodide, in most cases of asthma. But a certain number of patients remain that are not benefited by the former, and in whom the smallest dose of potassium iodide produces symptoms of iodism. The latter patients he had been in the habit of treating variously until he had read Professor Sée's article on the treatment of such cases with pyridine. Since then he has been employing, at his Poliklinik, pyridine inhalations according to Professor Sée's instructions. Nearly all the patients gave expression to a feeling of relief at the commencement of the inhalation, and said they felt the breathing grow easier and the chest expand more freely. Objectively, Dr. Lublinski could confirm these statements in emphysematous patients by noting that the respiration diminished in frequency, and the loud whistling ronchi ceased. There was no apparent effect on the heart, but the pulse not infrequently showed a diminution in the number of its beats, while its rhythm and quality remained unchanged. The invincible tendency to sleep, which Professor Sée mentioned as occurring only occasionally, supervened in most of Dr. Lublinski's patients. The patients all said they felt improved, and that they had passed better nights. They came to the Poliklinik twice daily to be treated, some of them quite a distance, which was strong evidence that their statements were grounded on truth. Still says Dr. Lublinski, it must not be denied that in a few cases symptoms manifested themselves that appeared dangerous. In one case, trembling of the limbs and nausea oocurred; in another, violent vomiting, with dizziness and headache; and another patient felt as if paralyzed. All these symptoms disappeared, however, after a time without leaving any further ill-effects on the patient's health. Still, they were not infrequent, and required careful attention. In decrepit individuals with emphysematous asthma, a weak heart, and poor circulation, and in those with valvular affections with symptoms of congestion, those symptoms are particularly prone to develop. An analysis of the cases treated by Dr. Lublinski shows them to have been two cases of emphysematous asthma complicated with phthisis, two of neurotic asthma, four of bronchial, and five of cardiac asthma. Of these twenty one patients that had been treated with the pyridine for a time (8–14–21 days), only the two with neurotic asthma could be said to be cured. Of the remaining patients, ten experienced marked improve- five received some relief and were at least able to pass the night in bed, and four were not appreciably benefited.

Dr. Lublinski employed pyridine in heart affections, independent of asthma, and the results, briefly stated, are that it gave marked relief in the feeling of oppression accompanying that disease. To sum up, the author would say that pyridine is not a specific in the various forms of asthma; that it finds its best application in cases of neurotic asthma, in which potassium iodide, nitro glycerin, and amyl nitrite are contra indicated, but even in these we must wait for further experience; that in the various other forms of asthma pyridine is a palliative, which must not be used indiscriminately; the cases require to be selected. —*New York Medical Journal*, April 17, 1886.

THE INFLUENCE OF STARVATION ON THE NERVE CENTRES.—DR. P. J. ROSENBACH, house physician to Professor J P Mierzejewski's clinic, has studied (*Vestnik Klin ee Sudeb Psikhiatri* , vol 1, part 2, and *St Petersburg Inaugural Dissertation*, 1883) experimentally, in dogs and rabbits—1, the microscopic changes occurring in the central nervous system in animals starved to death, 2, the influence of starvation on the excitability of the brain, and 3, the clinical symptoms resulting from the action of starvation on the nervous system

1 *Morbid Anatomy* —*a Spinal Cord* — The changes wrought by starvation were very marked and constant, though they were almost exclusively limited to the nerve-cells, the cells of the anterior horns presenting the most intense alterations The latter consisted in "opaque swelling" of the protoplasm, wax-like degeneration with loss of the processes, granular or hyaline degeneration or disappearance of the nucleus, sieve like vacuolization, and complete disintegration of the cell with fatty degeneration of detritus The longer the animal has lived under starvation, the greater are the alterations found, the lesser is the number of normal multipolar ganglionic elements met at an individual section All other conditions being equal, the most intense changes are observed in the neighborhood of the blood-vessels [That is, the morbid process in starvation follows the general law of spreading of diffuse degenerative processes in the spinal cord, as established by Dr James Ross, and as subsequently supported by N Popoff, Tchij, etc] The cells of the posterior horns undergo the degeneration in a far slighter degree than those of the anterior The neuroglia and nerve fibres show only some opacity and swelling [Like Dr Mankovsky (see the *London Medical Record*, Feb , 1884, p 73), Dr Rosenbach never saw anytning like "homogenous degeneration" of the interstitial tissue of the gray matter, as described by Dr N Popoff, neither did he see Popoff's "pigment degeneration" of the ganglionic cells] The vascular changes are the most marked in sections presenting the most intense degeneration of the nerve cells, and consist in intravascular accumulation of red and white blood-corpuscles in capillaries and veins, in hæmorrhage *per diapedesin*, and, relatively rarely, in "plasmatic" or "colloid exudation" (Lockhart Clarke's "granular" or "fluid disintegration")

b Brain —In all parts of the cerebral cortex (in the psychomotor area, as well as in the occipital, frontal and parietal lobes) there are present the same degenerative changes, but they are considerably less pronounced than in the spinal cord The ganglionic elements in the optic thalami, corpora quadrigemina, etc , present only slight opaque swelling The white substance everywhere is free from alterations The circumvascular spaces show marked dilatation, but without any accumulation of leucocytes

c Cerebellum —The degenerative process is localized in Purkinje's ganglia, shrinking of their protoplasm, vacuolization, and disappearance of the nucleus, being the changes prevalent

d Intervertebral and Sympathetic Ganglia —The same degenerative changes, except hæmorrhage and colloid metamorphosis, are found The lesions of the nerve cells in the intervertebral ganglia are so intense, as to create a distinct and characteristic macroscopic appearance The connective tissue of the structures is somewhat rarefied The sympathetic (cervical) ganglia present the same alterations, but in a slighter degree

Discussing the changes above described, the author points out that the same lesions are found in myelitis of traumatic and idiopathic (Leyden, Erb, Hayem, Vulpian) as well as toxic origin [as proved by the following experimental researches carried out under the guidance of Prof J P Mierzejewski Danillo's "On the Morbid Anatomy of the Spinal Cord in Phosphorus Poisoning," 1881, N Popoff's "On Acute Myelitis from Lead, Arsenic, and Mercury," 1882 (see the *London Medical Record*, December 1883, p 515), and Tchij's "On Alterations in the Spinal Cord in Poisoning by Morphia, Atropia, Nitrate of Silver, and Bromide of Potassium," in the *Meditz Pribav, k Morsk Sborn* , May and June 1883 —*Rep*] But, at the same time, there are present important distinctions between starvation on one side, and myelitis and poisoning on the other In starvation, there is absence of all inflammatory phenomena, such as infiltration of the tissues by leucocytes, formation of "granular cells," thickening of the vascular coats, etc , which are always found in myelitis and poisoning The degeneration and destruction in starvation are nothing but results of a defective nutrition, in consequence of arrested supply of nutritive material The localization of the degenerative process is determined by the nerve cells possessing a comparatively weaker power of resisting any disturbances of the general nutrition

2 *Excitability of the Brain* —Having carried out (conjointly with Professor V M Bekhtereff) a series of experiments on stimulation of the psycho motor centres in dogs, the author found that, to obtain the minimal motor effects, the strength of electric current must be greater than in the normal (non-starved) animal In other words, the electrical excitability of the brain is lowered under the influence of starvation

3 *Nervous Symptoms in Starvation* —Rabbits did not present any nervous symptoms at all As to dogs, there were observed some individual differences Thus "stray" or "street dogs" (or "no man's dogs"), accustomed to vicissitudes of life and half starving generally, in the beginning bear a complete hunger-diet good humoredly, and even preserve a cheerful disposition for a pretty long while Meanwhile the animals accustomed to good care and regular feeding at first manifest considerable restlessness, whine, and howl But afterwards all starved animals become quieter and listless, lie motionless, and do not even touch any food put before them Dr Rosenbach did not see anything like delirium or hallucinations of inanition, except in one case where the animal gnawed off a part of its paw in the last day of its life —*London Medical Record*, January 15, 1886

PICHI (FABIANA IMBRICATA) IN CYSTITIS —DR HAL C WYMAN, of Detroit, gives a record of five cases in which this drug was used in cystitis

The first case in which I used the fl ext pichi was early in January, when my attention was called to the drug by Dr J E Clerk, the chemist of this city A Mr G, aged 23 years, who contracted gonorrhœa a year or more ago, and who had stricture of the urethra, which I found necessary to divulse a few days before Christmas A copious hæmorrhage from the deep urethra followed the operation, and a few days later severe vesical tenesmus disturbed the patient so that sleep and appetite vanished All the symptoms of typical cystitis speedily developed Morphine, belladonna, hyoscyamus, and alkalies were used internally and by the rectum for a week without materially modifying the symptoms So irritable did the bladder become that it would not retain urine longer than five to fifteen minutes I now began the use of the fluid extract of pichi in 15-drop doses in water once in three hours The tenesmus and pain began to decline after twenty-four hours, the mucus and pus also to diminish in quantity, and at the end of the week the bladder would retain its contents three hours without causing the patient any inconvenience

This patient has now March 8, fully recovered I think the cystitis was of traumatic origin, the harsh manipulation of the vesical mucous membrane with the divulsing apparatus Thompson's instrument was the one used

Mr H, aged 71 years, had been getting up nights so pass urine for the last five years Ten months ago he found he could not empty his bladder, and was compelled to call a surgeon to use the catheter A severe chill followed, and he was very sick for two months, having the catheter used every day He learned to use it himself, and continued to use it daily until last February, when he had another chill, and his left testicle swelled and inflamed He was too sick to use the instrument I was summoned by his medical attendant in consultation, and opened a large abscess of the left testicle, and advised against further use of the catheter His prostate was greatly enlarged Opium and camphor suppositories relaxed the spasm of the catheter His urine was heavily loaded with urates Mucus, blood, and pus were present in abundance He was put on fluid ext pichi, and continued its use for three weeks He has made an excellent recovery

I might enumerate numbers of cases of lumbago and sciatica in the course of which urates were precipitated from the urine in large quantities, and which recovered while the patient was taking the pichi Combined with a potassium salt I have found it to act more quickly than any other remedy in bringing about a solution of the urates and relieving the rheumatic neuralgia so frequently associated with that unstable condition known as lithuria, phosphatism, etc A formula I have often used is—

℞	Fl ext pichi	℥i
	Potass nitrate	ʒi
	Simple elixir	℥iii
	M	

S —Teaspoonful once in two hours

—*Therapeutic Gazette*, April 15, 1886

PARALYSIS AFTER INJECTION OF IODO GLYCERINE FOR SPINA BIFIDA —At the meeting of the Wolverhampton and District Medical Society, on March 4, DR LYCETT exhibited a girl, aged 6, who, at birth was the subject of spina bifida over the upper part of the sacrum, forming a tense sessile tumor, of the size of an orange, having an ulcerated surface of the area of a crown piece, which, on healing, formed a thin membranous covering to that portion of the sac As it became thinner through expansion, it was tapped when she was six weeks old An ounce and a half of fluid was drawn off, and forty minims of iodo glycerine injected with a negative result The sac refilled about a week afterwards, about an ounce of fluid was withdrawn, and the injection increased to a drachm and a half, causing the sac, in a few days, to become obliterated Co incidentally with the shrinking, however, came loss of sensory and motor power in the legs, with incontinence of fæces and urine, the paraplegia, which persisted, being completely below, and incomplete above the knees Hydrocephalus also commenced immediately after the operation, and gradually increased until the third year, when the fontanelles closed without developing any nerve phenomena, or impairing the mental power The horizontal circumference of the head now measured twenty-two inches In the report of the committee, appointed by the Clinical Society of London to inquire into the subject of spina bifida, there was a case recorded, where paralysis supervened and persisted after the cure of the tumor, and appeared to be due to the treatment adopted In several cases temporary paralysis occurred, which passed off in a variable time, once complete paraplegia, which subsequently disappeared In three cases, hydrocephalus set in subsequently to the cure of the spina bifida Of the various operative measures, that by the injection of iodo glycerine was recommended in preference to any, as promising the greatest success, though the table of results showed that of 71 cases, only 35 recovered, 27 died, 4 were relieved, and 5 unrelieved As evidence of the frequency and serious nature of this affection, it appeared that it caused no fewer than 647 deaths in 1882, of which 615 were in children under one year of age —*British Medical Journal*, April 10, 1886

PHYSIOLOGICAL AND THERAPEUTIC EFFECTS OF ADONIDINE —DR HOBART ARMORY HARE, of Philadelphia, in an article on this subject, gives the conclusions of Durand, and then his own as follows

Durand says that in doses of gr ss adonidine—

1 Increases arterial tension
2 Regulates the heart-beat
3 Diminishes the frequency of the pulse
4 Increases the force of the cardiac contractions
5 Acts with rapidity, its effects being only present during its administration
6 Increases diuresis
7 Is well tolerated
8 That the indications for its use are the same as digitalis

He commends its use, especially in mitral insufficiency and interstitial myocarditis, and in palpitation of the heart Such a drug ought surely to be of signal service to the profession, for, though it is at present of high price, being made almost entirely by Merck of Darmstadt, there is no reason why a continued call for it should not make its cost within the reach of everyone, the adonis vernalis being by no means rare, its rhizome having been used as an adulterant for black hellebore, and the process of obtaining the glucoside is not expensive.

Conclusions.—Adonidine in all doses increases arterial pressure by stimulating the vaso-motor centres and by increasing the cardiac force.

In moderate doses it increases the pulse rate and force from the first, but when large toxic doses are given, it primarily slows the heart by stimulating the pneumogastric, and then increases pulse-rate by depressing the inhibitory nerves and stimulating the accelerator apparatus.

The slowing of pulse-rate is also in all probability due in part to increased arterial pressure, as under these circumstances the blood-paths are greatly diminished in calibre.

On the nervous system the drug has but little action, unless the quantity administered be enormous. Under these conditions it paralyzes the sensory side of the cord, but has no effect on the motor tract or on the efferent or afferent nerve trunks.—*Therapeutic Gazette*, April 15, 1886.

SANTAL OIL IN URINARY AFFECTIONS.—DR. A. P. GIPOULOU gives the following as the results of his use of the oil of yellow sandal-wood: 1. In chronic and obstinate gonorrhœa no especially remarkable effects were produced. 2. In acute gonorrhœa accompanied by severe vesical tenesmus, frequent and painful micturition, etc., the acute symptoms were speedily relieved, though the discharge diminished only gradually in quantity. 3. In a case of suppurative nephritis of the left kidney, in which there was frequent micturition and the urine was loaded with pus an improvement was noted within twenty-four hours, and at the end of a fortnight the pus had entirely disappeared from the urine. 4. A railway employe was suffering from acute cystitis, accompanied by tenesmus and bloody urine, which had resisted the action of ordinary remedies for over a month, he was relieved permanently in a few days by the use of yellow sandal wood oil. 5. In a number of cases of vesical catarrh equally rapid and permanent results were obtained. 6. In three cases of simple acute unilateral nephritis speedy relief was afforded by the same remedy. 7. In two cases of nephritic colic excellent results followed the administration of santal oil, the attacks were promptly cut short, and an apparent cure was the result. 8. Finally, he relates a case of acute Bright's disease following scarlet fever, in which there was general anasarca and the urine was heavily loaded with albumin. During a treatment of four or five days with diuretics the œdema increased, but within two days after giving santal oil the improvement was marked, and at the end of a week the anasarca had disappeared and no more albumin could be found in the urine.—*Journal de Med. de Paris*, February 14, 1886.

MODIFICATION OF PIRIGOFF'S METHOD.—At the recent Congress of Russian practioners, Professor TAUPER described and demonstrated on the dead subject an operation for removal of the foot, which he believes has several advantages over Pirogoff's amputation. Standing on the outer side of the limb, he commences an incision at the insertion of the tendo Achillis, and carries it forward just below the external malleolus to the dorsum of the foot, and then vertically downwards on the inner side in front of the heel. When the middle line of the sole is reached the incision is carried along it backwards and prolonged upwards to the starting point at the insertion of the tendo Achillis, a flap having thus been cut consisting of the inner side and half of the sole of the heel. The joint is then opened, the external ligaments being first divided and then the internal. The astragalus is seized with the bone forceps and removed, and the anterior part of the foot cut off by Chopart's line, nothing being left but the os calcis, the soft coverings of which on the inner aspect are untouched. The os calcis is seized with the bone forceps and turned so that the articular surface is towards the operator. The forceps are now taken by an assistant, who holds them tightly, the operator then saws the bone longitudinally in two, the outer half, which is free, is removed, the inner half remaining attached to the flap. The ends of the tibia and fibula are then sawn off just above the malleoli. The cut surfaces of these will be found to correspond almost exactly with that of the os calcis, which is now brought into apposition with them. The advantages claimed for this operation are: 1. The posterior tibial artery is itself untouched, only its branches being divided. 2. The insertion of the tendo Achillis, as well as its bursa, are not injured. 3. The surfaces of the os calcis and of the leg bones correspond very nearly to one another.—*Lancet*, April 3, 1886.

ANTIDOTE TO COCAINE POISONING.—DR. F. SCHILLING describes a case of cocaine poisoning, coming on after the drug has been locally applied for the extraction of a tooth. The patient was a woman aged 28, in the seventh month of pregnancy. The injection of two drops of a 20 per cent. solution of cocaine caused sufficient anæsthesia for the extraction of the tooth. As the patient was leaving the room the dentist noticed that her eyes were fixed, and a few minutes after making her sit down she became unconscious, reacting to no stimulus. The injection of ether had no result. During the unconscious state, which lasted over half an hour, the breathing was quiet, the pulse 86, and regular, the eyes were wide open, with medium sized pupils, and the conjunctival reflex had disappeared. The patient could not be roused by shouting, but after a time began to call her husband by name. Dr. Schilling, considering that the condition was due to anæmia of the brain, advised the inhalation of amyl nitrite. The first inhalation seemed to rouse her, and after the second she could answer questions hesitatingly, but correctly. She was well in a short time. As the author states, it is a question whether the symptoms were not due to shock, as the patient was pregnant. He, however, considers this an improbable explanation.—*London Medical Record*, March 15, 1886.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

THE EDITOR OF THIS JOURNAL would be glad to receive any items of general interest in regard to local events, or matters that it is desirable to call to the attention of the profession. Letters written for publication or containing items of information should be accompanied by the writer's full name and address, although not necessarily to be published. All communications in regard to editorial work should be addressed to the Editor.

SUBSCRIPTION PRICE, INCLUDING POSTAGE.

PER ANNUM, IN ADVANCE	$5 00
SINGLE COPIES	10 CENTS.

Subscriptions may begin at any time. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address,
JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 65 RANDOLPH STREET,
CHICAGO, ILLINOIS.

PELVIC ABSCESS IN THE MALE.

At the meeting of the New York Academy of Medicine, held on April 15, DR. T. HERRING BURCHARD, Lecturer on Surgical Emergencies at Bellevue Hospital Medical College, read a paper on "Pelvic Abscess in the Male," which was of special interest on account of the presence at the meeting of a patient on whom Dr. Burchard had performed laparotomy for the relief of the condition named. The details of this case may be found in our New York letter for this week.

While pelvic abscesses in the male have not attracted the same surgical attention as those occurring in the female, the serious nature of the affection, Dr. Burchard thinks, is quite as great in the one as in the other. He also believes that it is of more frequent occurrence than the meagre literature of the subject would lead us to suppose. By pelvic abscess he desires to be understood as meaning a phlegmonous inflammation occurring in the superior portion of the pelvic cavity—below the cavity of the abdomen, from which it is separated by the pelvic reflections of the peritoneum, and above the muscular floor formed by the levator ani muscle. It is not to be confounded with abscesses of the abdomen—typhlitic, perityphlitic, etc.,—nor with those originating below the levator ani, in the ischio rectal fossa. Mr. Henry Morris divides such iliac abscesses of pelvic origin into two groups: (1) the subperitoneal, and (2) the sub aponeurotic. The former, he claims, are prone to spread widely, in both an upward and a downward direction, reaching the upper boundaries of the abdomen and even burrowing behind the diaphragm, while the latter are more circumscribed, forming between the fascia iliaca and iliac muscle, and producing caries or necrosis of the bone.

The clinical history and symptoms naturally vary according to the acuteness or latency of the attack. Should the attack be acute, both the constitutional and the local disturbance are proportionately greater, and it may readily be mistaken for one of general or circumscribed peritonitis, on account of the similarity of the symptoms. Abscesses which form thus acutely are more likely to evacuate themselves spontaneously, either in the rectum or the bladder, than those of a subacute or chronic character. The inference is logical that suppuration, when it occurs, does so a considerable time before it makes itself manifest by external tumefaction, and that the delay in getting the evidences of abscess is not due to absence of pus, but rather to the difficulty which the pus has, on account of the suppurative process, in coming to the surface. During all this time, however, the constitutional evidences of internal suppuration are more or less pronounced, and a carefully conducted examination at this stage may prevent many months of tedious suppuration, with its attendant evils.

Nevertheless, chronicity, rather than acuteness, seems to be the rule with pelvic phlegmons in the male, except in cases having a traumatic origin, and the affection most frequently occurs in the poorly nourished and cachectic, in whom inflammatory processes are slow. The diagnosis in such cases is often very difficult, partly on account of the inaccesibility of the parts affected, and partly owing to the perplexity of symptoms arising from so many different tissues, organs, blood vessels and nerves being implicated in the inflammation. Speaking further in regard to diagnosis, Dr. Burchard said that inflammation, occurring here, manifests itself, in addition to local distress or pain, which is generally severe in character, by the usual constitutional disturbances. After tumefaction has occurred, another set of symptoms arises, due to pressure on sensitive nerves and organs.

Another feature, peculiar to these abscesses, is their tendency to burrow, and there are very great dangers attendant thereupon. Their natural destination should be the peritoneum, and such, doubtless, would be the case, were it not that the extremely dense fibres of the levator ani and the prostatic muscles, which are largely composed of firm, fibrous tissue, present an almost impenetrable obstacle. The next most natural route would seem to be the rectum, and here many of these abscesses are evacuated. Many, however, mount the pelvic cavity, and appear within the abdomen, after which their course is erratic.

Clinically, it is important to distinguish between an inflammatory condition pure and simple—a cellulitis simplex—and the same condition after it has passed into the suppurative stage The presence of pus cannot be recognized at too early a period It is likewise necessary to distinguish between a pelvic cellulitis and general or localized peritonitis, and also between this and cystitis, proctitis and prostatitis Rheumatism and neuralgia, too, must be borne in mind Surgically, it is necessary to differentiate between abdominal abscesses, ileo-pelvic abscesses, pelvic abscesses, abscesses of the ischio rectal fossa and perineal abscesses Exceptional possibilities must be carefully considered—such as hernia strangulated in the pelvic foramina, passage or impaction of renal calculi, acute inflammation of the psoas muscle, typhlitis and perityphlitis, and lastly, scrofulous, malignant, tubercular and syphilitic diseases of the pelvic glands

The treatment of these abscesses, externally, resolves itself into treatment of the cellulitis before suppuration, and treatment after suppuration is established In the first case rest, morphia, quinine in free doses, local refrigeration, and, possibly, local depletion by leeches to the perineum, are required In employing cold in this or any other inflammatory condition about the rectum, Dr Burchard thinks that nothing equals in efficacy and comfort the continuous douche of cold water, which passes up and immediately returns through a double flow blind tube The great mistake that is often made by the inexperienced in the application of either this or the ice coil is in applying it too cold at first The water at first should be warm, and then gradually cooled until ice water can be used, and with astonishing relief

During the stage of acute inflammation frequent rectal explorations should be desisted from, as they often do more harm than good After suppuration may reasonably be expected, a careful examination, under anæsthesia, should be made, in order that the abscess may be evacuated into the rectum at the earliest possible moment If evidence of internal suppuration is present, and there is reason to believe that pus is burrowing upwards, an abdominal exploratory incision is obviously demanded If this can be made without opening the cavity of the peritoneum, it certainly should so be done The object to be attained, however, is the evacuation of the pus, but we cannot always be successful in this, as adhesions will at times form impassable barriers

RICH LEGACIES WELL BESTOWED

We are reminded by the account of the laying of the corner stone of the new building of the College of Physicians and Surgeons, the Medical Department of Columbia College, of New York, on the 24th of April, 1886, of the very liberal and yet remarkably considerate bequests of the Vanderbilt family for the advancement of medical science and art, and thereby the more efficient prevention or relief of human suffering First, the late Wm H Vanderbilt donated $500,000, of which $200,000 was for the necessary building lots and the remainder for erecting new college buildings, reserving perhaps something as an endowment of the scientific laboratories Next his daughter, Mrs Sloane, added $250,000 for the founding of a Maternity Hospital and endowing it with perpetual free beds, which was to occupy a part of the same lots, and finally the four sons of Wm H Vanderbilt have given $250,000 more to establish on the same premises an extensive Clinic and Free Dispensary for the poor By thus aggregating the magnificent sum of $1,000,000, one of the oldest medical colleges in this country is placed in a condition not only to furnish facilities for the most complete education of medical men in all departments, both scientific and practical, but also to prosecute such original researches as add to the sum of human knowledge and increase the resources for relieving human suffering for generations to come And yet the Maternity Hospital, and the Clinic and Dispensary, will be an ever present resource for the relief of large numbers of the suffering poor

If the actual relations of medical education to the health and comfort of the human family are studied, we doubt whether $1,000,000 has ever been donated to one general purpose with more wisdom than in the present instance And if the men and women in our country possessed of great wealth would give more thought to the modes by which they could so bestow a portion of their wealth as to make it the means of perpetually increasing the knowledge of diseases and their remedies and in the same ratio diminishing human suffering and prolonging human life, the example furnished by the Vanderbilt family would find many followers Wealthy men in Chicago have invested more money in building and furnishing mere *club-houses*, than would be required to endow and perpetually maintain the scientific and practical laboratories of all the regular medical colleges of this city The comparatively small sum of $100,000 donated to the Trustees of the Chicago Medical College as a special or perpetual endowment of her histological, physiological, pathological and chemical laboratories, in addition to her present equipments, would at once add an efficient department of original investigation as active as in any of the institutions of

Europe We mention the Chicago Medical College, because it was the first medical college to establish and maintain a thoroughly graded system of medical instruction in this country, and a high standard of requirements for graduation, but we would also rejoice to see every meritorious medical college in our country in the possession of similar endowments

It is too much the custom of our people to divide their surplus wealth among too many institutions, whether educational or otherwise, and by so doing the greater part of it becomes immediately absorbed in buildings and grounds, leaving little or nothing as permanent endowments for maintaining perpetual and efficient instruction and research Let those in possession of a surplus of this world's goods think of these things

DR GRAHAM'S ADDRESS

The address of Dr D W Graham to the graduating class of the Woman's Medical College, at the closing exercises a few weeks ago, which is published in this issue of The Journal, is so different from the usual address of the kind, in this country at least, that it may not be inappropriate to call more particular attention to some of the many suggestive ideas embodied in it As was pointed out in an editorial article in The Journal of May 23, 1885, the usual valedictory, inaugural, graduate, and alumni address contains more or less assertion that the profession in this country is in a state of scientific and educational depravity In the address under consideration, however, the author has risen above such pessimistic views and instead of taking an icteric view of the past and present he speaks wisely and hopefully of the present and future

The first point upon which Dr Graham touches, a matter which has been much discussed of late years, is the fitness and capacity of woman for the study of medicine That women are both fitted and capacitated for the study of medicine few will deny, save upon the grounds that woman's place is the home circle, and that she is physically unsuited to the demands of modern medicine But let us take another aspect of the case, leaving out of view for the present those who intend to practise medicine in their own (civilized) country A recent report of the New York Medical Missionary Society says, according to the *Medical Record*, of April 17 "About forty millions of heathens die every year with scarcely any medical aid There are two white missionaries to about one million of heathens There is one medical missionary to about ten millions of heathens Modern medicine and surgery appear miraculous to the heathens, it is often very difficult to prevent them from even worshipping a doctor Their gifts in gratitude for medical aid would shame many Christians A medical missionary can, to a large extent, obtain his own support His medical skill will open doors otherwise closed to the gospel" So much has been said in the journals of the past two or three years of the Chinese and Hindoo customs which prevent the attendance upon sick women of male physicians that it is only necessary to make this allusion to them Here, then, is the great field for the female physician, and this has been fully shown in the past year by the results of the munificent charity of Lady Dufferin It is very doubtful if any purely missionary society will be able to show the results, within the next five years, that will follow Lady Dufferin's charity

But apart from this, there is a field in home medicine for woman—a fact that is so clearly shown in Dr Graham's address that it need scarcely be discussed The female physician, on account of the demands of the profession, may not live so long as she might otherwise, but it is to be remembered that "the life is long which answers life's great ends" On the other hand, her knowledge of medicine may so guide her as that she will avoid, and, better than the man, induce other and non professional women to avoid, many of the follies of civilization, so that life may be longer, happier, and more fruitful If medicine has a place in moral education, surely medically educated women have some part of that place, and it must be claimed that the education in which medicine has a place is the triple education—moral, mental and physical To quote the words of Dr Graham "There is a positive demand for the services of medically educated women Here are opportunities enough and scope enough for all shades of tastes and all degrees of talents," in preventive medicine, in investigating the questions relating to the defective and helpless classes of society, the moral defects and deformities of youth and adult life, and in placing the triple education of which we have just spoken on a sound and scientific basis "Women are peculiarly adapted for much of this kind of work" Of "the thousands of women of our land without occupation, with physical and mental capacity for a long life of usefulness, with noble and philanthropic aspirations," many "will find in these fields abundant work which will yield the most beneficent and tangible results"

Dr Graham makes some very pertinent remarks on the "overcrowded condition of the medical profession" It is not so much those who look for places inflammatory condition pure and simple—a cellulitis simplex—and the same condition after it has passed into the suppurative stage The presence of pus cannot be recognized at too early a period It is likewise necessary to distinguish between a pelvic cellulitis and general or localized peritonitis, and also between this and cystitis, proctitis and prostatitis Rheumatism and neuralgia, too, must be borne in mind Surgically, it is necessary to differentiate between abdominal abscesses, ileo-pelvic abscesses, pelvic abscesses, abscesses of the ischio-rectal fossa and perineal abscesses Exceptional possibilities must be carefully considered—such as hernia strangulated in the pelvic foramina, passage or impaction of renal calculi, acute inflammation of the psoas muscle, typhlitis and perityphlitis, and lastly, scrofulous, malignant, tubercular and syphilitic diseases of the pelvic glands

The treatment of these abscesses, externally, resolves itself into treatment of the cellulitis before suppuration, and treatment after suppuration is established In the first case rest, morphia, quinine in free doses, local refrigeration, and, possibly, local depletion by leeches to the perineum, are required In employing cold in this or any other inflammatory condition about the rectum, Dr Burchard thinks that nothing equals in efficacy and comfort the continuous douche of cold water, which passes up and immediately returns through a double flow blind tube The great mistake that is often made by the inexperienced in the application of either this or the ice coil is in applying it too cold at first The water at first should be warm, and then gradually cooled until ice water can be used, and with astonishing relief

During the stage of acute inflammation frequent rectal explorations should be desisted from, as they often do more harm than good After suppuration may reasonably be expected, a careful examination, under anæsthesia, should be made, in order that the abscess may be evacuated into the rectum at the earliest possible moment If evidence of internal suppuration is present, and there is reason to believe that pus is burrowing upwards, an abdominal exploratory incision is obviously demanded If this can be made without opening the cavity of the peritoneum, it certainly should so be done The object to be attained, however, is the evacuation of the pus, but we cannot always be successful in this, as adhesions will at times form impassable barriers

RICH LEGACIES WELL BESTOWED

DR GRAHAM'S ADDRESS

The address of Dr D W Graham to the graduating class of the Woman's Medical College, at the closing exercises a few weeks ago, which is published in this issue of The Journal, is so different from the usual address of the kind, in this country at least, that it may not be inappropriate to call more particular attention to some of the many suggestive ideas embodied in it As was pointed out in an editorial article in The Journal of May 23, 1885, the usual valedictory, inaugural, graduate, and alumni address contains more or less assertion that the profession in this country is in a state of scientific and educational depravity In the address under consideration, however, the author has risen above such pessimistic views and instead of taking an icteric view of the past and present he speaks wisely and hopefully of the present and future

The first point upon which Dr Graham touches, a matter which has been much discussed of late years, is the fitness and capacity of woman for the study of medicine That women are both fitted and capacitated for the study of medicine few will deny, save upon the grounds that woman's place is the home circle, and that she is physically unsuited to the demands of modern medicine But let us take another aspect of the case, leaving out of view for the present those who intend to practise medicine in their own (civilized) country A recent report of the New York Medical Missionary Society says, according to the *Medical Record*, of April 17 "About forty millions of heathens die every year with scarcely any medical aid There are two white missionaries to about one million of heathens There is one medical missionary to about ten millions of heathens Modern medicine and surgery appear miraculous to the heathens, it is often very difficult to prevent them from even worshipping a doctor Their gifts in gratitude for medical aid would shame many Christians A medical missionary can, to a large extent, obtain his own support His medical skill will open doors otherwise closed to the gospel" So much has been said in the journals of the past two or three years of the Chinese and Hindoo customs which prevent the attendance upon sick women of male physicians that it is only necessary to make this allusion to them Here, then, is the great field for the female physician, and this has been fully shown in the past year by the results of the munificent charity of Lady Dufferin It is very doubtful if any purely missionary society will be able to show the results, within the next five years, that will follow Lady Dufferin's charity

But apart from this, there is a field in home medicine for woman—a fact that is so clearly shown in Dr Graham's address that it need scarcely be discussed The female physician, on account of the demands of the profession, may not live so long as she might otherwise, but it is to be remembered that "the life is long which answers life's great ends" On the other hand, her knowledge of medicine may so guide her as that she will avoid, and, better than the man, induce other and non professional women to avoid, many of the follies of civilization, so that life may be longer, happier, and more fruitful If medicine has a place in moral education, surely medically educated women have some part of that place, and it must be claimed that the education in which medicine has a place is the triple education—moral, mental and physical To quote the words of Dr Graham "There is a positive demand for the services of medically educated women Here are opportunities enough and scope enough for all shades of tastes and all degrees of talents," in preventive medicine, in investigating the questions relating to the defective and helpless classes of society, the moral defects and deformities of youth and adult life, and in placing the triple education of which we have just spoken on a sound and scientific basis "Women are peculiarly adapted for much of this kind of work" Of "the thousands of women of our land without occupation, with physical and mental capacity for a long life of usefulness, with noble and philanthropic aspirations," many "will find in these fields abundant work which will yield the most beneficent and tangible results"

Dr Graham makes some very pertinent remarks on the "overcrowded condition of the medical profession" It is not so much those who look for places as those who make places, who find them, not those who stay in the rear and wait, like Micawber, for something to turn up The recent graduate, like the one of long standing, has a trust and responsibility in the honor of the profession, and should he see those going astray who are old enough to set a better example, let him or her hold still more firmly to honor and duty, and remember that medicine when followed as a science and profession is the noblest of all arts, but when entered into with any other view it is the most despicable of trades

ADENINE—A NEW ANIMAL POISON

In March, 1885, Kossel published an account of a new base, to which he gave the name adenine, which he extracted from the spleen and pancreas, though he says that it is present in all vegetable and animal cells It is an alkaloid, and isomeric with hydrocyanic acid, and Kossel claims that it proceeds from the physiological decomposition of nucleine, of which the cellular nuclei are composed Nucleine may be decomposed, when isolated, into albumen, phosphoric acid and adenine, and when adenine is treated with nitrous acid it is transformed into hypoxanthine or sarcine

M Gautier now claims that this discovery of Kossel, and its confirmation by M Morelle, in Gautier's laboratory, uphold his leucomaine theory M Morelle finds that adenine is present under normal conditions, and has a powerful influence on the medulla, causing asphyxia and collapse when injected under the skin of guinea pigs and frogs, the symptoms being somewhat similar to those caused by muscarin and digitalin Accordingly Gautier now announces a general medical law which must henceforth be taken into consideration Not only the most highly organized cells constantly manufacture poisonous substances, but their nuclei and protoplasm have a groundwork, consisting of an aggregation of most potent toxic molecules

We may very properly ask, with M Colin, why animals which are fed on the spleen and pancreas do not die of this terrible poison? M Gautier replies that the quantity of the poison in a few pounds of spleen or pancreas is too small, that though adenine is isomeric with hydrocyanic acid, it has not the same properties, and that all living cells contain a substance isomeric with hydrocyanic acid But does he not mean that cells once living contain, when dead *and treated with chemical agents*, poisonous substances? This does not prove that the poisonous substances were in the cells while they were a part of the living body If it could be shown that adenine is a cumulative poison it would seem to follow that animals fed constantly on the spleen and pancreas should in time show symptoms of the poisonous action

SOCIETY PROCEEDINGS

CHICAGO MEDICAL SOCIETY

Stated Meeting, April 19, 1886

THE PRESIDENT, E J DOERING, M D,
IN THE CHAIR

DR G C PAOLI read a paper entitled

THE REASONS WHY FEMALE PHYSICIANS ARE DESIRABLE IN INSANE ASYLUMS

He demonstrated that the most eminent specialists in pschiatry in the United States are a unit in maintaining that female physicians are best qualified for treating the female insane Many States have passed laws requiring one female physician to be allotted to each one hundred female insane in their asylums

DR J G KIERNAN said eminent authorities had already pointed the relation which exists between uterine disease and insanity Popular opinion is growing in favor of the employment of female physicians in the treatment of the female insane

DR WM T BELFIELD reported nine cases of

IMPERMEABLE STRICTURE TREATED BY ELECTROLYSIS

(See THE JOURNAL, April 24, p 455)

During the past two years he has treated thirty seven cases of stricture by electrolysis, and except for strictures located within an inch of the meatus, and for strictures of large calibre elsewhere, considers it preferable to dilatation and urethrotomy for the following reasons 1 It will pass through any stricture, however tight, rigid, long or tortuous 2 As a rule it causes no pain, bleeding, chill, nor urethral fever 3 It is always devoid of danger 4 Its effects are lasting

In certain numerous cases electrolysis is not merely a preferable, but really the only practicable treatment Such are, 1, old, rigid, cartilaginous strictures in men of middle or advanced age, where urethrotomy is dangerous and dilatation ineffectual, 2, impermeable strictures, 3, tight and rigid strictures with perineal or scrotal fistulæ

Dr Belfield then narrated the successful treatment by electrolysis of nine such cases In three of these there was complete retention of urine, the bladder being distended above the umbilicus, these strictures were absolutely impermeable, to urine from within as well as *to instruments from without* In each case a No 10 electrode (French) was passed into the bladder in less than twenty minutes, permitting the immediate introduction of a catheter In each of these cases perineal section would have been, without the battery, inevitable

In the remaining six cases Dr Belfield, as well as other surgeons, had failed in attempts to pass bougies into the bladder, yet as the patients were still enabled to force a feeble, dribbling stream outward, these strictures were theoretically permeable, though practically impermeable In these also a small electrode readily entered the bladder in one or two sittings

In one case, seen in consultation with Dr Miller, the patient had a series of tight, rigid, impermeable strictures, and twenty-seven fistulous openings in the scrotum and perineum, he had submitted to both internal and external urethrotomy, and to numerous unsuccessful attempts at dilatation, was urinating every half hour, day and night In fifteen minutes a No 10 bulb entered the bladder, that night patient rose only once to urinate, and for the first time in several years the urine flowed entirely from the meatus and not from the fistulæ

The unfavorable results obtained by various physicians in their attempts at electrolysis have been caused by the use of improper currents, whereby heat was generated and the urethra cauterized causing violent inflammation and even extensive sloughing When properly used, the heat produced is insignificant, with six to fifteen small cells and a weak fluid, the cicatricial tissue constituting the stricture is dissolved away but not cauterized Since cicatricial tissue is but scantily supplied with blood, and is therefore poorly nourished, it yields to a dissolving current which is insufficient to disturb the healthy urethral tissues

Dr L L McArthur said he had treated with success by electrolysis one case in which numerous operations had already been performed When patient came to him he could pass a No 8 sound, used No 9 electrode, and the patient can now pass No 15 American sound Never had any pain or difficulty in micturating since the operation

Dr M B Brown detailed two cases of impermeable and two of permeable stricture, in which he used electrolysis with good result

Dr C Fenger said he must confess that he was somewhat surprised by seeing the announcement of Dr Belfield's paper "nine impermeable strictures treated by electrolysis" He had tried electrolysis a few years ago, but never had any success from it It surprised him that Dr Belfield should meet with nine impermeable strictures in a very short period of time, while Sir Henry Thompson has only met with three impermeable strictures in his whole life By hearing the paper read, however, he understood that Dr Belfield does not mean to say that the strictures were impermeable in the strict sense of the word—the only correct one—but only meant that it was difficult to pass any instrument through these strictures Sir Henry Thompson, in his 'Diseases of the Urinary Organs," of 1882, p 28, says "Impermeability cannot be held to describe a character, a physical quality of the stricture itself, but rather indicates the quality of the surgeon who has treated it" Impermeable stricture is a contradiction in terms, it is not heard of so much now as it was twenty years ago Dittel of Vienna, in speaking about relative and absolute impermeable strictures, says a stricture may be impermeable for one man, or at a certain time, and permeable for another man, or at another time Other modern authors on surgery, as Konig and Albert, speak about the matter in a similar way

The second surprise to him was the advocated treatment by electricity, or electrolysis There has always been in his mind a suspicious halo of mysticism about the electrolysis, whether applied to the different forms of surgical tumors or to strictures of the urethra He understands from the paper, that the electrolysis does not mean galvano caustic treatment, although quite recently Jardin, of Paris, uses a small galvano cautery knife for passing slowly through the stricture Dr Belfield warns very justly against cauterization The non-caustic electrolysis is to me a very mystic process Dr Fenger remembers years ago of one of Billroth's clinics which he spoke about electrolytic treatment of venous angiomas of the face, that he expressed as the result of his experience the following "The electrolystic needle has no more or other effect on the tumor in question, than the mere mechanical disturbance of the tissue elements, that is, than any other needle not connected with a battery would produce"

Frankly, Dr Fenger said that the historical fate of electrolysis in strictures, as well as elsewhere, up to date, has invariably been the following Ever since Tripier, in 1864, and Mallez, in 1872, applied the electrolysis in strictures of the urethra, this method of treatment has come to the surface once every two or three years only to disappear again, and it has never been able to take any hold on the profession, not because it has not been tried, but rather because it has not been found superior, or even equal, to the other methods Dittel states that, on the rather promising representations of Tripier and Mallez, he tried electrolysis in three cases of very narrow stricture It proved of no effect in any of the cases, and in one of them a local inflammation followed Sir Henry Thompson does not even mention the electric treatment anywhere in his writings about strictures, but warns very emphatically against any method of cauterization Konig says, in a very short appended notice, that only the short and soft strictures depending upon a polypus or warty growth of granulation-tissue are proper objects for cauterization, either chemical (Duchamp), or galvano caustic (Middeldorf) Otis, our American authority in this line of surgery, does not mention electrolysis with a word

Newman, of New York (*Medical Record*, August 12–19, 1882), is not only the advocate of electrolysis in this country, but has written so assiduously and specified the method so minutely as to have it termed, in the foreign literature, "Newman's method" In 1882, Newman's old and new cases numbered twenty three only In reporting Newman's articles for Virchow's *Jahresbericht*, Guterbock, of Berlin, says that "Newman's method has already, in 1872 and 1876, been criticised so thoroughly that not much more need be said about it" Dikmann, in New York *Medical Record*, Jan 5, 1884, reports twenty eight cases Graf, in Norway, reports, in 1884, two cases treated by 'Newman's method," and Verneuil, in

1884, recommends Jardin's "electrolyse lineavu"—that is, cauterization

Thus the electrolytic treatment of stricture has been tried off and on for over twenty years, but has only taken hold here and there, sporadically, and for a short time It has in the urethral, not any more than in the other fields of surgery, as yet to any extent replaced the more rational treatment by mechanical means

The electrolysis may, however, have a further trial, and if the success in extensive resilient strictures, as in one of Dr Belfield's cases, should prove to hold good for other cases of that kind, it is possible that this treatment will have a better fate in the future than it has had in the past

Dr R Tilley said he did not consider electrolysis to be the proper term to be used in connection with the use of electricity in the manner suggested Electrolysis, in the ordinary acceptation of the term, means the decomposition by electricity of water, or tissues, being in the nature of a chemical decomposition He would like to know how far apart the electrodes were placed (Dr Belfield replied that the negative electrode was placed in the urethra, and the positive pole in any position on or near the penis, according to the effect intended) He could not see how electrolysis could be produced with the electrodes so far apart, and a weak fluid, without a cauterizing effect From his extensive experience of cocaine in producing contraction of the tissues in the nose, he would expect to secure as good if not better results, reasoning by analogy, in its use in strictures of the urethra as in the use of electricity He would think its internal application would be followed by wonderful results

Dr W T Belfield closed the discussion by saying that in reply to Dr Fenger's criticism that these strictures were not impermeable, he would remind him that he called six of them "theoretically permeable, practically impermeable," that is, a feeble stream was forced through, but no instrument could be introduced The remaining three were absolutely impermeable to urine as well as instruments They were water-tight, the bladder in each case being immensely distended Dr Fenger, in the cases where he attempted electrolysis, evidently made the usual mistake he employed a strong current and *cauterized*, but did not electrolyze, the stricture With a proper current he would probably have a better result Sir Henry Thompson and Prof Dittel do not, it is true, endorse electrolysis, but he knows that neither of them has ever fairly tried it, they have contented themselves with the vague, unfavorable verdict of those who, having once or twice misused the current, attribute to the battery the faults which belong to themselves Thompson's conservatism and intolerance are notorious, he bitterly opposed Bigelow's litholapaxy (without trying it) until it was adopted by everybody else

Possibly, as Dr Fenger says, these is no "urgent necessity" for any other method than urethrotomy and dilatation, but surgeons who have to treat many such strictures as those described in the paper under discussion, think otherwise These methods certainly possess one point of national economic value which electrolysis lacks, namely they assist in repressing the excess of population by quietly removing many patients

Electrolysis "bobs up" and down only when ignorantly used, when properly employed it comes to stay

To Dr Tilley he would say that the action is properly termed "electrolysis," it is the same effect as is seen in the decomposition of water, and is produced by the same current During the action of the current a white foam and bubbles come up alongside the instrument Cocaine causes contraction of blood vessels in the urethra as well as in the nose, but it can not, so far as he is aware, remove cicatricial tissue in either locality

In conclusion, he would repeat that the secret of success lies in securing chemical force and avoiding heat, the former removes the stricture easily and painlessly, the latter causes violent inflammation and sloughing

OSTEO PLASTIC RESECTION OF THE FOOT

Dr C Fenger then presented a patient before the Society with the following words I wish to bring this patient before the Society to illustrate the results of an operation called "osteo-plastic resection of the foot," and devised by Wladimnoft and Mikulicz The operation consists in removal of the heel, soft parts and bones, and then uniting the remainder of the foot to the tibia in the position of an artificial pes equinis As you will see, the patient has on a plaster cast from the toe to below the knee, and is able to walk in this cast without crutch or cane He limps because the leg operated upon is two inches longer than the other one, and not because of inability to step on the leg He will have in future to wear a high sole or heel under the well foot While this plaster cast is being taken off I shall pass round the specimen of the removed heel and say a few words about the operation

The patient had suffered for one year from a chronic traumatic osteo myelitis of the tarsus resulting in anchylosis of the joints, fistulæ on dorsal side of tarsus and a loss of substance of the skin of the heel Pirogoff's or Syme's operation being out of the question, the choice was only between a supra malleolar amputation and the osteo plastic resection This operation was performed fourteen months ago Union of the bones took place in four to six months, and it is only the subsequent small operations for bringing the toes in dorsal flexion that have required so long a time before the patient has been able to commence to walk

The plaster cast being now removed, you will find the foot in the axis of the leg in equinus position, the toes dorsally flexed to a right angle with the foot There is active flexibility of the toes and some active mobility of the foot This mobility, however, does not take place between the united surfaces of the tibia and fibula on the one side and the scaphoid and cuboid bones on the other, as can be seen by examining the prominences representing the rudimentary newly formed malleoli—but the mobility takes place in the joints of the metatarsus As to the question whether these joints will be able to bear the strain of the weight of the body during walking with the foot in this abnormal position, this patient of course proves nothing as yet But from the other cases operated upon, in all nineteen, we can conclude that we have the right to expect a useful foot for walking A patient operated upon by Socin, in Basle, is able without boot—the boot devised by Miculicz, which I now pass round for inspection—or cane to walk, but can walk all day long and perform a farmer's work in the field You will further notice that the walking surface of the foot, being the plantar surface of the heads of the metatarsal bones and the toes, is considerably larger than the surface which either a Syme's or a Piragoft's operation would leave the patient to walk on This, together with the active mobility of the toes, is regarded as an advantage that functionally places the osteo plastic resection superior to the two other operations mentioned

We find by examining the foot everywhere painless on pressure, and consequently there is nowhere any recurrence of the disease

Mikulicz feared that the anterior tibial artery might not be sufficient for the blood supply of the foot, his method of operating dividing all the branches of the posterior tibial artery I had the same apprehension, and changed the incision so as to save one of the terminal branches of the last named vessel, namely, the internal plantar artery This fear is not unfounded, as in one of Sordina's cases operated upon according to Mikulicz's description, gangrene of the foot necessitated supramalleolar amputation on the fourth day The mortality of the operation is as yet none, but as all the nineteen cases have fallen within the last few years except Wladimnoff's, and consequently have been treated antiseptically, it cannot be said that the danger is less than either in Syme's or Pirogoff's operation There is no doubt that the functional results are far superior to that of a supramalleolar amputation even if the patient will always have to wear the Mikulicz boot Consequently it may be safe to say that osteo plastic resection has already a legitimate place, although perhaps as yet not strictly enough defined, in the surgery of the tarsus

LETTER FROM PARIS

(FROM OUR OWN CORRESPONDENT)

Origin of the Blood, from a Medico legal Point of View—Death of Professor Bouchardat

Dr Masson, Pharmacien major in the French army, has published an essay on *The Origin of the Blood, from a Medigo legal Point of View.* The difficulties attending this class of researches are very great, and the expert is often placed in an awkward predicament when called upon to give his opinion in a court of justice M Masson has endeavored in his essay to facilitate these researches so that the expert may always be ready with a definite reply as to whether a blood stain was produced by the blood of a man or an animal After giving the different modes of procedure to ascertain this fact, the author states that the great cause of the alteration of fresh blood globules resides in the dampness of the medium or vehicle in which they are contained, the effect of which is to prevent the evaporation of the water of the plasma In dried blood, the globule resists for a much longer time the causes of alteration, no liquid can regenerate the altered globules In the mensuration of the globules by the microscope, we may obtain an approximation of one fifth of a micromillimetre, but in reality, a variation of this infinitesmal quantity does not permit of any differentiation Moreover, in consequence of the great variability of the globular dimensions in the same species in a physiological state (Hayem), and particularly in a pathological state, (Kelsch found them augmented in volume in impaludism, and Malassez in chlorosis, according to this last author, the dimensions of the globules are reduced in cancer), the experiments must take a great number of mensurations and then strike an average

It is advisable to have at least five series of 30 mensurations, in five sittings and on five different preparations In operating on dried blood with the liquid of Virchow (solution of potash at 30 per cent) the conclusions arrived at are as follows the mean diameter of hæmatics being superior to $\frac{1}{130}$th part of a millimetre, the blood may belong to a man, a guinea-pig, a dog, a rabbit Below $\frac{1}{135}$th part of a millimetre, the blood does not very probably belong to a man, but to one of the animals which, after him and the guinea-pig, possesses the greatest number of globules Below $\frac{1}{140}$th of a millimetre the blood does not certainly belong to a man The author incidentally mentioned that the presence of nuclei can alone permit one to pronounce between the blood of oviparæ and that of mammifers

Dr Bouchardat, the eminent Professor of Hygiene at the Paris Faculty of Medicine, died on Thursday, April 8, in the 80th year of his age He occupied this chair for thirty four years, from which he had to retire not only on account of his great age, but because he was affected with deafness He took his degree in 1832 and was soon after promoted to Agrégé He was elected Member of the Academy of Medicine in 1850, and became its President in 1866 His funeral took place in the midst of a large concourse of friends and colleagues, but according to his desire there was no official representation The chief mourners were his two sons, one of whom is a Surgeon-Major in the French Army, and the other a professor at the School of Pharmacy The President of the Academy of Medicine at its meeting, April 13, after having retraced in touching terms the long scientific career of the lamented Professor, closed the meeting without proceeding any further, as a mark of respect

DOMESTIC CORRESPONDENCE

LETTER FROM NEW YORK

(FROM OUR OWN CORRESPONDENT)

Memorial Exercises in Honor of Dr Flint—Pelvic Abscess in the Male—Second Trial of General Shaler—The Vanderbilt Clinic—The "Medical Record" and the Academy of Medicine

The meeting of the New York County Medical Association, held April 19, was entirely devoted to memorial exercises in honor of the late Professor Austin Flint, and it proved a most impressive and interesting occasion The mourning decorations which had been put up in the lecture hall of the Carnegie Laboratory at the time of the Bellevue College Commencement last month, still remained in position, and the attendance of members was much larger than at any previous meeting of the Association, being considerably larger than even that at the meeting on the eve of the last annual session of the State Asssociation, in November, when Dr Flint read the admirable paper on *The Elements of Prognosis in Bright's Disease*, which has since attracted so much attention

It was deemed advisable to have brief addresses from as many of his associates, friends and former pupils as possible in the time at command, rather than a lengthened eulogy by some specially selected memorialist, and the plan proved a most excellent one The interest was thus maintained to the very last, while the high attainments, illustrious services and noble character of the departed master were presented in a more striking and varied manner, as viewed from so many different stand points, than could possibly have been accomplished by any one man

The exercises were opened by a carefully prepared and effective address by the President, Dr Charles A Leale, after which the resolutions, which had been drawn up by a special committee consisting of the Vice President, Dr John Shrady, and Drs E S F Arnold and J W S Gouley, were read by the Chairman, Dr Shrady The first, after the reading of the resolutions, to pay his tribute of affection and respect to the memory of Dr Flint, was Professor Lewis A Sayre, who spoke in a most feeling manner, and in the course of his remarks alluded to one of his traits which was especially worthy of imitation by all This was the lifelong habit of always setting about, at once, whatever he had to do, so that nothing ever came from his pen which was not complete and perfect in every detail In illustration of this, he stated that since Dr Flint's death, there had been found among his papers the address which he was to have delivered in August next before the British Medical Association, and which, even at this early date, was already entirely finished When this fact was known to the authorities of the Association, he had no doubt that they would request a copy of it for publication with the proceedings of the year's session

Among the others by whom addresses were made were the following —Prof Wm H Welch, of the Johns Hopkins University, Baltimore, Dr T R Varich, of Jersey City, Surgeon General of the State of New Jersey, and Drs E G Janeway, J Lewis Smith, J D Bryant, F E Dennis, Isaac E Taylor, Ellsworth Eliot, H M Biggs, and George L Peabody, of the Association A touching tribute was also paid by Prof Frank H Hamilton, who was associated with Dr Flint and the late Dr James P White in founding the Buffalo Medical College

Letters of regret were then read by the Secretary, Dr P Brynberg Porter, from Prof N S Davis, of Chicago, Dr E M Moore, of Rochester, President of the New York State Medical Association, Dr E D Ferguson, of Troy, Secretary of the Association, Dr Joseph R Hutchinson, of Brooklyn, and Dr Wm Detmold, of this city, the first President of the County Association A large number of other similar letters were received from members, as well as invited guests from a distance The Association will, no doubt, publish an official account of this memorial meeting, and in it will be included series of resolutions passed by the Association of Physicians, Louisville, Kentucky, and by the Erie County Medical Society, which were not received in time for the meeting

At the meeting of the Academy of Medicine on April 15, Dr T Herring Burchard read a paper on *Pelvic Abscess in the Male* Dr Burchard has met with five cases of pelvic abscess in his personal experience, and he gave the detailed histories of all of them in his paper That of the last and most interesting one, however, will suffice here Peter Murphy, aged 28, married, a porter by occupation, always temperate, and robust and strong up to March, 1882, at which time he was suddenly seized, after some unusual exertion, with sharp pains in the right iliac fossa, which lasted thirty hours This paroxysm terminated in a dull, heavy pain, which extended across the hypogastrium, into the left iliac region, and which continued with greater or less severity up to the time of his operation

In June, 1884, he was admitted to St Luke's Hospital, suffering from the same intense pain Poultices were applied, but no suppuration occurred In the following August, after several unsuccessful aspirations, an abscess of the right lumbar region, midway between the iliac crest and ribs, was evacuated by the late Prof James A Little The case was regarded by him as one of perityphlytic abscess At this time the patient's condition was very bad, with severe, steady pain deep in the pelvis and perineum, and darting pains extending through the rectum into the right testicle and down the sciatics There was also priapism, with involuntary nocturnal emissions In December, a second abscess was opened by Dr Little Although suffering more or less constant pain, his health improved during the winter, but in March and July following, other abscesses formed in the side and on the body of the ilium These were also opened In August and September he had the pain and constitutional disturbance of forming abscesses, but five incisions failed in giving vent to pus

October 5, patient's health evidently failing All the old pains have returned A careful examination, under ether, was made , but, owing to the thickness of the abdominal walls from fat, this was very unsatisfactory Rectal examination revealed nothing A localized phlegmon over the ilium, two inches below and to the front of the posterior superior spinous process was opened, and carious bone detected This was removed by gouge and augur The superficial caries led into a larger abscess cavity in the ilium, and this in turn communicated, by a direct opening, with the iliac fossa The finger, introduced through the bone, could detect nothing abnormal within the abdomen The carious bone being thoroughly removed, a lint of bichloridized oakum was introduced through the ilium, and the wound partially closed

October 29 After great pain, referred to the hypogastrium, right iliac region and right testicle, another abscess formed, and discharged through the opening in the bone The source of this could not be detected, and both external and rectal examinations failed to throw light on the case

In the early part of December another abscess formed within the pelvis, but instead of discharging through the opening in the ilium, pointed over the crest, and was evacuated at this point The patient's condition was now critical in the extreme He was rapidly losing strength and flesh, and was being worn out with constant pain and suppuration, while albumen, with hyaline casts appeared in his urine It was felt that something effective ought to be done, and yet there was nothing tangible upon which to found a diagnosis, beyond the fact that at irregular intervals abscesses in the right iliac region would form and discharge Repeated examinations were negative in results, but the indications clearly were to open the abdominal cavity (of course employing every antiseptic precaution), and, if possible, by stripping up the peritoneum from the right iliac fossa, to seek and remove the source of irritation

Operation—St Elizabeth's Hospital, February 1, 1886, Drs H Marion Sims, Mandeville, and C W Stimson, assisting, An incision was made commencing just above and posterior to the posterior inferior spinous process of the ilium, and following the bone downwards for a distance of five inches The dissection was carried through the abdominal muscles, and the peritoneum exposed This Dr Burchard endeavored to detach from the subjacent fascia, but so firmly adhered was it that, in spite of very gentle manipulation, it tore A flat sponge was introduced through the laceration, to hold back the intestines, while with the hand a thorough exploration was made Almost immediately a mass of adhesions was found that led to an abscess cavity which occupied the posterior half of the fossa, and extended, like a great sinus, directly from the ilium on the line of the pelvis and down into its cavity No dead bone could be detected The sinus having been laid open, its walls, which were almost cartilaginous, were thoroughly revivified with a dull curette The sinus through the bone was likewise curetted, and some carious bone removed Two drainage-tubes of soft rubber, eight inches long, were carried directly to the bottom of the sinus, and the whole thoroughly irrigated with a solution of the bichloride of mercury, 1 to 2000 The abdominal wound was now closed with deep and superficial sutures The incision leading through the bone was kept open, and dressed from the bottom with iodoform and bichlorodized oakum A superficial dressing of borated cotton was made over all

The patient rallied nicely On the third day the temperature rose to 102$\frac{1}{5}$° and the pulse to 120, and there was a very slight circumscribed peritonitis On the sixth day the patient's temperature was practically normal, and the discharge from the tubes scarcely amounted to half a drachm After this the tubes were shortened gradually, and at the end of three weeks were entirely removed, firm granulations having filled up the cavity of the sinus The opening through the bone has likewise been filled in with new tissue, and is now closed Dr Burchard then said that he had the pleasure of exhibiting the patient to the Academy in better health than he has enjoyed for years, and he certainly presented all the appearances of a man in robust physical condition

In the second trial of General Shaler for bribery in connection with the selection of an armory site for one of the militia regiments, the jury has again disagreed, this time standing four for conviction and eight for acquittal On the 26th of April is set down General Shaler's trial before the Mayor, on a charge of malfeasance in office as President of the Board of Health

On April 24th the corner-stone of the new building of the College of Physicians and Surgeons was laid by Mr George W Vanderbilt, the youngest son of the dead millionaire, Mr Chauncey M Depew delivering the address The four sons have just donated $250,000 for the erection and maintenance of a building for clinical purposes, to be known as the "Vanderbilt Clinic," which makes the total gifts of the Vanderbilt family to the College amount to about $1,000,000

P B P

P S—The New York *Medical Record* it will be seen, has seen fit to take your correspondent to task for the reference made in his last letter to the recent changes in the constitution and by laws of the New York Academy of Medicine, which it thinks "will be looked upon as unwise and unnecessary, if not actually malicious" Certainly nothing was further from his thoughts than any idea of maliciousness when he wrote it, but it did seem right to him that when a body of such high standing and influence, as the Academy of Medicine, deliberately cuts itself off, to a certain extent at least, from the profession throughout the country, this fact should be known to the profession at large The course which the Academy has pursued, it need hardly be said, has been most painful to many of those who have hitherto been among its best friends and most efficient and earnest supporters

Even in the best regulated folds black sheep are apt to be found, but if one is to accept the statements of the *Record*, the Fellows of the Academy are all very much in the blissful condition of certain perfectionists in some of the religious bodies, who claim to have attained such a state of sanctity that they cannot commit any sin It is not to be supposed that the Academy would take into its fellowship any one who was known to be a thief and black leg, but if it should afterwards be found that any of its Fellows were of such a character, it would certainly seem desirable that it should have some means for getting rid of the offending members As to whether any irregular practitioner will ever be received by it (against which, as has been pointed out, there is no restriction whatever in the constitution or by-laws), seems likely to depend on the men composing the committee on admissions hereafter When the application of a candidate has been favorably acted upon by this committee, it is an almost unprecedented thing for the applicant to be blackballed, and, in the growing laxity of feeling as regards irregulars in this community, it is not by any means inconceivable that at some time a committee on admissions may give its endorsement to the application of a candidate of the kind alluded to

Since the last letter was written a case has become known which would not have been referred to at all in this correspondence except for the strictures of the *Record*, but which furnishes a somewhat striking commentary on some of the statements made in that letter A Fellow of the Academy having done some action (which need not be mentioned here) believed to be worthy of censure a member of the Council, a gentleman of refinement and great eminence in the profession, was asked to remonstrate with him in regard to the supposed offence, but when the latter attempted to do this, on more than one occasion, if the writer is correctly informed, he was coolly greeted with the polite advice to "go to h—ll" Now what can the Academy do about it? In former times the course to be pursued would have been sufficiently plain, and there would have been no hesitation in taking suitable action

---

INJUSTICE TO DR BARNES

To the Editor of the Journal

Dear Sir —My attention was to day called to an editorial in your journal of the 10th inst, under the heading of "Injustice to Fancourt Barnes," which does me great injustice I therefore request that you give this note equal prominence in an early issue

My name having been misprinted "Cutler" in the review, and the fact that Barnes's book contains a greater number of words than mine, are claimed as proofs that the reviewer was not familiar with either book A careful comparison shows that Dr Barnes copied *all of my words and definitions*, with one or two exceptions Most of the errors copied could not have been made so continuously and peculiarly alike had not the printer of Barnes's book used my printed page as part of his copy Such uniform, exact and constant repetition of definitions punctuation, etc, in their sequence throughout several thousand words could have occurred in no other way Barnes's book contains very few strictly *medical* terms not found in mine The mass of his padding consists of chemical, botanical and pharmaceutical terms to be found in all the general dictionaries A prominent journal, in reviewing Barnes's book, said that his additions were "*not particularly or at all scientific*" In many cases, after giving certain of my words and definitions, he has repeated the same word and given another combination of definitions, evidently taken from the common dictionaries The remark that "Barnes's dictionary contains errors in words that are not in Cutter's dictionary at all, and other errors in words that are correctly given by Cutter," is very true, and many of them present evidence that Barnes was not capable of writing an original work of the kind

I assert that no "injustice in regard to this matter has been done to Dr Barnes in this country," and that this claim of piracy is not a fable, neither is Dr Barnes's book superior to mine, as a comparison of the two books will show any person capable of judging which is most reliable I cannot expect to be afforded the space for citing the many facts at my disposal in proof

In the concluding paragraph of your editorial it is stated that the firm who imported Barnes's book voluntarily, and without investigation, returned their importation to England This suppression of Barnes's book did not take place until after a considerable correspondence, and a suit was about to be commenced My counsel had prepared overwhelming proof that Barnes had pirated the whole of my book I wrote to this effect to all the prominent British journals of medicine, but, with one exception, they refused to publish So much for simple justice to one not in the country to defend himself

My dictionary was an original work, exactly as claimed in the preface, and was the product of years of hard study To steal such a work is to inflict a much greater injury than the reprinting of an essay or work of that nature I should not have even protested had it been simply reprinted in England as "Cutter's Dictionary" I have no quarrel with any one, but I shall certainly protect my rights

Respectfully, G R Cutter

52 Bedford Ave, Brooklyn, N Y, April 17, 1886

THE ADDRESS IN MEDICINE BEFORE THE BRITISH ASSOCIATION

To the Editor of the Journal

Dear Sir —I hope you will not take it amiss if an humble reader of The Journal dissents from your editorial statement in connection with the selection of Dr J S Billings, of the Army, "to deliver the address in Medicine before the next meeting of the British Medical Association in place of the late Professor Austin Flint," that "the well known ability of Dr Billings and his familiarity with general medical literature, makes the selection one *eminently* proper" The ability of Dr Billings is, of course, well known, and his familiarity with general medical literature is unquestioned, but a great many have presumed to doubt whether the selection of a bibliothecary, however noted and conspicuous, who has often disclaimed any practical acquaintance with disease, who has probably not written a prescription for twenty years, and who would not presume to undertake the charge of a sick person, is one "eminently proper," while such famous pathologists live as Henry I Bowditch, Francis Minot, Albert L Loomis, Henry W Draper, Francis Delafield, William Pepper, James Tyson, James T Whittaker, Wm H Welch, Palmer Howard, N S Davis, and a dozen more If the British Medical Association does not know of these men, the British Medical Association has much to learn

PHYSICIAN

CAUTERIZATION OF THE CERVIX UTERI, A REMEDY FOR THE OBSTINATE VOMITING OF PREGNANCY

TO THE EDITOR OF THE JOURNAL

Dear Sir —In THE JOURNAL of to day, April 24, is a letter from Dr M O Jones, of this city, taking Dr Jos Taber Johnson, of Washington, D C, to task for forgetting to credit the writer with originating the treatment by nitrate of silver of the vomiting of pregnancy It seems Dr Jones suggested this method to Dr Sims in 1872 Dr Sims regarded it as original, wrote in the *Lancet* concerning it soon afterwards, and gave it the stamp of advanced knowledge It never struck me that way by reason of the following quotations In Bennet's work on the Uterus,[1] he says

"The discovery of the frequent existence of inflammation, with or without ulceration, during pregnancy, is one of vital importance, inasmuch as it affords a key to most of the accidents and morbid symptoms of the pregnant period It appears to have escaped the notice of all the Continental writers —such as Lisfranc, Duparcque, etc —who have recently paid attention to uterine diseases, and no English work or publication on midwifery or the diseases of women contains *the most distant allusion* even to the possible existence of such disease during the pregnant state " But twenty four years before this date, in 1840, Bennet says that M Boys de Loury called his attention to it And he adds ' I believe that I am authorized to attribute to M Boys de Loury this important discovery, as I certainly never heard any other practitioner before him allude in the most cursory mannner to the subject, and I *am not acquainted even with a hint respecting it in* the entire range of medical literature M Boys de Loury's discovery was briefly noticed in 1843, by one of his house physicians, M H Costilhes, in a thesis sustained before the Paris Faculty of Medicine M Costilhes's cursory notice was the only one that had appeared of this pathological fact in any language when the first edition of the present work was published Since that time I have devoted great attention to the elucidation of *inflammatory disease of the cervix* and to chronic metritis generally *during pregnancy*, and have ascertained that they are of frequent occurrence, that they are the *keystone* to the diseases of the *pregnant state*, and the most *general cause* of laborious pregnancy, *obstinate sickness*, moles, abortions, miscarriages, and hæmorrhage The results of my researches on these points as contained in the present chapter, were read before the physiological Section of the British Association at Southampton on September 11 1846

"The influence of *inflammation of the uterine neck*,[*] as of the uterus generally, on the *functions of digestion*, is *perhaps the most marked*, the *most important*, and *the most common of all the sympathetic relations* which we have to study, nor can we be surprised, when we consider how intimate the connection is between the *uterus* and the *stomach* in the *physiological state* *As an illustration of this* physiological connection, I would again recall to mind *the sickness* that generally accompanies the increased vital activity of the *uterus* during the *first months of pregnancy* " (Page 104)

"In some cases vomiting constantly takes place after food, and even at other times When this is the case, the body of the uterus is often implicated, *and all remedies may fail permanently to arrest the vomiting until the uterine disease be subdued* " (Page 107)

"The *dyspeptic symptoms* observed in obstinate leucorrhœa are nearly invariably the result of the *sympathetic reaction* on the *stomach* of the inflammatory disease of the uterine neck " (p 103) These quotations are from the chapter dealing with married women Now let us see what Bennet says of the treatment

"The only caustic that can be used with advantage *in inflammation of the cervix without ulceration or hypertrophy is the nitrate of silver*, *which acts*, however, more as an *astringent than as a caustic*" (p 237)

"The *existence of pregnancy*, so far from being an obstacle to the local treatment of inflammatory and ulcerative *disease* of the *uterine neck*, is a *strong reason why* it should be adopted and carried out without delay " "During the first six or seven months, it is the *absolute duty* of the medical attendant to treat the disease, as by curing the ulceration, or even by modifying its irritability, not only is much suffering spared to the patient, but abortion is often prevented The local treatment must consist in astringent injections and cauterization with nitrate of silver, " (p 296)

Again "This has emboldened me to apply them (*the above remedies*) in the early stages of pregnancy in some females in whom repeated abortions had occurred, with a *view to diminish congestion* and to *carry on gestation* I have done this repeatedly with success " (p 297)

It is perfectly clear that Bennet treated the congested cervix of the pregnant female to overcome the sympathetic irregularities of the digestive organs, and to use his own language, "I have devoted great attention to the elucidation of inflammatory disease of the cervix and to chronic metritis generally *during pregnancy*, and have ascertained that they are of frequent occurrence, that they are the *keystone* to the diseases of the pregnant state, *and the most general cause of laborious pregnancy, obstinate sickness*," etc Who can fail to see that the pathology of this matter belongs to M Boys de Loury, stated by him in 1840, and that Bennet laid down the treatment in 1846 at Southampton, twenty six years before Dr Jones presented it to Dr Sims at Chicago as a new idea Very respectfully,

R STANSBURY SUTTON M D

BOOK REVIEWS

The Essentials of Histology, Descriptive and Practical, for the Use of Students By E A Schafer, F R S, Professor of Physiology, University College, London, etc 8vo Philadelphia Lea Brothers & Co 1885

The author of this book is well known, and is recognized as a writer of authority He has attempted in this volume to supply the student with directions for the microscopical examination of the tissues, at the same time describing the essential facts of the science so as to make a complete elementary text-book on histology

Each chapter is prefaced by a few paragraphs in which directions are given as to how specimens must be prepared for examination These are detailed and will enable a student readily to demonstrate all that is essential in the histology of the various tissues and organs The book is most excellently illustrated It will undoubtedly be found very useful by many teachers and students in college, as well as by those who are working by themselves and to whom the practical suggestions of the book will be particularly useful Dr Schafer is so well known to pathologists and students of histology for his exceedingly careful work and natural abilities, that it seems unnecessary to give any detailed account of his work

An Atlas of Clinical Microscopy By Alexander Peyer, M D Translated by A C Girard, M D, Assistant Surgeon U S Army First American from second German edition, with additions Ninety Plates, with 103 Illustrations, Chromo-Lithographs New York D Appleton & Co 1886

This book is handsomely illustrated by well drawn original figures It covers a field that has not been perfectly covered before The aim of the work is to furnish illustrations of the objects seen in the various secretions, excretions and exudates commonly examined for clinical purposes The text is brief and will serve chiefly as a guide to rather than as a full explanation of the objects illustrated The scope of the work can be better comprehended by quoting the titles of its main divisions 1 Microscopic Examination of the Blood, 2 Of the Milk, 3 Of the Urine, 4 Of the Sputum, 5 Of the Stool, 6 Of the Contents of the Stomach, 7 Of Fluid from Abdominal Tumors, 8 Of Secretions from the Female Sexual Organs, 9 Various Micro organisms Provoking Disease Each subject is considered in detail For example, from urinary sediments the various forms of crystalline bodies are shown, blood, pus, tube casts, mucus, all forms of cylinder or tube casts, epithelium, spermatozoa, and so forth The drawings, with the exception of only two plates, are original with the author A reference book of this kind has long been needed by students of clinical medicine, and this one will certainly be found useful It is fortunate that the translation has been made by one who is familiar with the subject

ASSOCIATION ITEMS

AMERICAN MEDICAL ASSOCIATION

The Thirty-seventh Annual Session will be held in St Louis, Mo, on Tuesday, Wednesday, Thursday and Friday, May 4, 5, 6 and 7, commencing on Tuesday at 11 A M

The delegates shall receive their appointment from permanently organized State Medical Societies and such County and District Medical Societies *as are recognized by representation in their respective State Societies*, and from the Medical Department of the Army and Navy, and the Marine Hospital Service of the United States

Each State, County, and District Medical Society entitled to representation shall have the privilege of sending to the Association one delegate for every ten of its regular resident members, and one for every additional fraction of more than half that number *Provided*, however, that the number of delegates for any particular State, territory, county, city or town shall not exceed the ratio of one in ten of the resident physicians who may have signed the Code of Ethics of the Association

Secretaries of Medical Societies, as above designated, are earnestly requested to forward, *at once*, lists of their delegates

Also, that the Permanent Secretary may be enabled to erase from the roll the names of those who have forfeited their membership, the Secretaries *are, by special resolution*, requested to send to him, annually, a corrected list of the membership of their respective Societies

SECTIONS

"The Chairman of the several Sections shall prepare and read, in the general sessions of the Association, papers on the advances and discoveries of the past year in the branches of science included in their respective Sections "—*By-Laws*, Art 11, Sec 4

Practice of Medicine, Materia, Medica and Physiology—Dr J T Whittaker, Cincinnati, Ohio, *Chairman*, Dr B L Coleman, Lexington, Ky, *Secretary*

Obstetrics and Diseases of Women and Children—Dr S C Gordon, Portland, Me, *Chairman*, Dr J F Y Paine, Galveston, Texas *Secretary*

Surgery and Anatomy—Dr Nicholas Senn, Milwaukee, Wis, *Chairman*, Dr H H Mudd, St Louis, Mo, *Secretary*

State Medicine—Dr John H Rauch, Springfield, Ill, *Chairman*, Dr F E Daniel, Austin, Texas, *Sec'y*

Ophthalmology, Otology, Laryngology—Dr Eugene Smith, Detroit, Mich, *Chairman*, Dr J F Fulton, St Paul, Minn, *Secretary*

Diseases of Children—Dr W D Haggard, Nashville, Tenn, *Chairman*, Dr W B Lawrence, Batesville, Ark, *Secretary*

Oral and Dental Surgery—Dr John S Marshall, Chicago Ill, *Chairman*, Dr A E Baldwin, Chicago, Ill, *Secretary*

A member desiring to read a paper before a Section should forward the paper, or its *title* and *length* (not to exceed twenty minutes in reading), to the

Chairman of the Committee of Arrangements, at least one month before the meeting —*By Laws*

Committee of Arrangements—Dr Le Grand Atwood, St Louis, Missouri, *Chairman*

AMENDMENTS TO BY-LAWS

By Dr Foster Pratt, Mich—Each Section shall nominate its Chairman and Secretary—all other nominations to be made, as now, by the nominating Committee

By Dr I N Quimby, N J—Create a new Section, to be known as the Section on Medical Jurisprudence WM B ATKINSON, M D, *Permanent Secretary*

1400 Pine St, S W cor Broad, Philadelphia

PROGRAMME OF SURGICAL SECTION —*Tuesday* — Dr William M Mastin, of Mobile, Ala, "Venous Blood Tumors of the Cranium in Communication with the Intra Cranial Venous Circulation, especially the Sinuses of the Dura Mater", Prof Moses Gunn of Chicago, "On the Value of an Attempt at Enucleation in a Neuroma which seems to demand Resection of the Nerve, illustrated by a case", Dr B A Watson, of Jersey City, "Fibre or Spindle-celled Sarcomatous Tumors, with the report of a case and presentation of the specimen", Dr Joseph Ranssohoff, of Cincinnati, "Treatment of Thoracic Aneurisms by Introduction of Wire, with a case", Professor E Andrews, of Chicago, "Incisions and Drainage of Lumbar Abscesses"

Wednesday—Prof Christian Fenger, of Chicago, "Osteoplastic Resection of the Foot, Excision of the Heel", Dr W T Belfield, of Chicago, "Digital Exploration of the Bladder, with report of twelve cases including five Vesical Tumors and two cases of Prostatotomy", Dr Robert Newman, of New York, "Galvano Caustic in Diseases of the Prostrate Bladder and Urethra", Prof E E Glover, of Terre Haute, Ind, "The Treatment of Anal Fistula associated with Phthisis", Dr J T Jelks, of Hot Springs, Ark, "Stricture of the Urethra"

Thursday —Dr Theo A McGraw, of Detroit, "Experimental Researches with reference to Sutures of the Intestines", Prof S McF Gaston, of Atlanta, "Surgical Relations of the Ilio Cæcal Region", Dr Henry H Smith, of Philadelphia, "What is the Proper Treatment of Penetrating Wounds of the Abdomen," being the opening remarks on the discussion of the subject, with discussion by Dr B A Watson, of Jersey City, Dr J McF Gaston, of Atlanta, Dr E H Gregory, of St Louis, and Dr H H Mudd, of St Louis, Dr Henry O Marcy, of Boston, "Hernia and the Best Method of Cure", Dr R Harvey Reed, of Mansfield, Ohio, "Some of the Complications in Strangulated Hernia"

RAILWAY CERTIFICATES TO THE ASSOCIATION MEETING—SPECIAL NOTICE —To delegates and others who will attend the meeting of the American Medical Association, St Louis, May 4 to 8 Parties located east of Buffalo, Niagara Falls, Pittsburgh and Parkersburg, will apply by mail to Secretary of Trunk Line Committee, 346 Broadway, N Y, for certificates Parties west of points named above and east of the Mississippi River, and north of the Ohio River, will apply to Geo H Daniels, Commissioner C P C, Chicago, Ill, for certificates Parties south of the Ohio River, and east of the Mississippi River, will apply to M Slaughter, Commissioner, Richmond, Va Parties from Missouri River points, and from Chicago, will apply to E P Wilson, Arbitrator, Chicago Points in the west and local points on the lines centering in St Louis, will be arranged for, by agent at starting point or upon arrival here

Delegates in making application to the above named persons for a certificate, must not forget to enclose a two cent stamp to pay postage on the return letter enclosing to them the certificate This must be done to insure the certificate being sent Any delegate who fails, after making every effort, to get a certificate in due form, will take a receipt from the ticket agent at the point from which he starts, for amount of full fare paid by him, coming to the meeting, and in this receipt be particular to have named the form and number of ticket, and the road over which he will come If not directly on one of the lines entering into this arrangement of reduced rates, pay your fare only to it, and then pay your full fare from that point, securing your certificate or receipt as above directed State, County or City Societies can apply for the number of certificates they may wish, and have the number wanted sent in one envelope instead of applying individually

Round trip tickets from Chicago, Ill, also from New York (339 Broadway), Richmond, Va, and Washington City, D C, by Chesapeake & Ohio Railroad, from Philadelphia via Penn Central and B & O

Members of the American Medical Association, or members of any medical societies, who may see the above, will please report it to individual members, or their societies, and try to get a notice of same in their city or county newspaper

R M JORDAN, M D,
Chairman Transportation Committee

St Louis Mo

RAILWAY FACILITIES TO THE ASSOCIATION MEETING —The regular through trains of the Illinois Central Railroad from Chicago to St Louis will afford excellent accommodations for delegates who wish to attend the meeting of the American Medical Association at St Louis the first week in May The night express, with Pullman sleeping cars, leaves Chicago at 8 30 P M, and arrives in St Louis at 7 A M The rates are $7 50

The rates on the Baltimore and Ohio Railway for those coming from the East and South east are full fare coming and one-third fare returning

RAILROAD FARES —The Boston & Albany Railroad will, upon application at their office, 232 Washington St, Boston, sell to delegates and *their families* tickets to St Louis and return for one and one third fares for round trip A parlor car, to run through from Boston to St Louis, will be attached to the train leaving Boston at 3 P M, May 1st

MISCELLANEOUS

In Memoriam—Austin Flint, M. D., LL. D.—At a regular meeting of the New York County Medical Association, held April 19, 1886, the following was unanimously adopted:

Whereas, It has pleased God, in the exercise of His Divine Will, to remove from the sphere of his usefulness our esteemed co-worker, Austin Flint, M. D., LL. D., revered abroad, but best loved at home; and

Whereas, It is but proper that we take to ourselves that consolation which comes from the rehearsal of his many virtues; Therefore, be it

Resolved, That as an Association to whom he gave his latest work, and ever his cherished counsel, we add our own to the many other testimonials of his worth;

Resolved, That we recognize in him an author of marvelous industry, who has made his impress on the medical thought of the age, modest and just, but still a master of deliberate statement, conscientious in the recognition of the labors of others, and despising not the humblest contributor to that science to which he devoted his life; a practitioner of his art without device, zealous for the dignity of his calling, suave, considerate and gentle; one who worthily gained the gratitude of his patients and will ever live in their most blessed memories; a consultant who dispensed rich stores of knowledge, ever judging kindly, more careful of the rights of others than his own, cheery and abounding in charity for his brethren; a teacher, hand-in-hand with his pupils, analytical, pains-taking, less eager for glory than exactness, ever approachable and always ready with a reason for the faith that was in him; and a man in all the walks of life blameless, "who hath borne his faculties so meek" and "hath been so clear in his great office," and who, laboring to the last, hath fallen in sight of the promised land of his cherished hopes.

And be it also *Resolved*, That we tender to those of his own household and kinship our heartfelt sympathies, knowing well that to his son, his life was a pæan of touching affection, and to his widow one long benediction.

John Shrady, M. D.
E. S. F. Arnold, M. D. } *Committee.*
J. W. S. Gouley, M. D.

A Sanitary Convention at Kalamazoo, Michigan, under the auspices of the State Board of Health, will be held on Tuesday and Wednesday, June 1 and 2, 1886. There will be sessions the first day at 2.00 P. M. and 7.30 P. M.; on the second day at 9 A. M., 2 P. M., and 7.30 P. M.

At each session of the Convention there will be addresses or papers on subjects of general interest pertaining to public health, each paper to be followed by a discussion of the subject treated.

The admission to all sessions of this Convention will be free, and the ladies are cordially invited. The invitation is especially extended to health officers to be present and take part in the discussions. The objects of the Convention are the presentation of facts, the comparison of views, and the discussion of methods relating to the prevention of sickness and deaths, and the improvement of the conditions of living.

Among the subjects which it is expected will be presented and discussed are the following: 1. History of Investigations Concerning Micro-organisms, and the germ theory of disease. 2. Personal duty touching prevention of spreading communicable disease: (*a*) From the standpoint of the lawyer; (*b*) From the standpoint of the clergyman; (*c*) From the standpoint of the health officer. 3. Disinfection. 4. Sanitary condition of public buildings in Kalamazoo. 5. The diseases incident to poverty. 6. Healthy Homes. 7. The need of a public hospital in Kalamazoo. For further information address H. B. Hemenway, M. D., or Rev. M. W. Haynes, Secretaries, Kalamazoo, Michigan.

Medical Missions.—Mr. T. Fisher Unwin is about to publish a work entitled "Medical Missions: their Place and Power." It is written by the Rev. John Lowe, the Secretary of the Edinburgh Medical Missionary Society, and will contain an introduction by Sir William Muir. It will also be further embellished with a medallion portrait of Dr. John Abercrombie, the founder of the above Society.—*Lancet*, April 17, 1886.

Medicines for Internal and External Use.—By a notice recently issued in the District of Potsdam in Prussia, it is ordered that the directions to be affixed to medicines for internal use shall be written on white paper, and to those for external use on bright red paper, on which writing with black ink is easily legible. The latter must also be distinctly marked "external." An order regulating the color of the paper to be used has existed since 1825, but its provisions have gradually been transgressed; hence the new regulations. Such regulations as that to which allusion is now made, are scarcely calculated to obviate the danger of mishap. Difference in the color of paper is useful, so far as it goes; but it appeals to the sense of sight alone, and, as we have already urged, it should be substituted or supplemented by an appeal to the sense of touch, by a difference in the configuration of the bottles used respectively for "internal" and "external" medicaments.—*British Medical Journal*, April 17, 1886.

Death of Dr. Hiram Nance.—Dr. Hiram Nance, of Kewanee, Ill., died at his residence in that place on April 6. He was born in Floyd Co., Ind., in 1822. He graduated at the Missouri Medical College in 1845. He was one of the founders of the Military Tract Medical Society, was one of its first Presidents, and a member at the time of his death, was a member of the Illinois State Medical Society, and for twenty-five years a member of the American Medical Association. He was known throughout Northern Illinois as a leading practitioner, a kind physician, and a man of high personal worth and attainments.

The Grocers' Company and Biological Science —A city company officially represented at a lecture on Physiology is surely a sign of the times So, too, is a lecture, not on the art of dining, but on a novel and somewhat abstruse physiological research, conducted with funds provided by the company The audience which gathered to hear Dr Wooldridge's lecture at the University of London, on April 13, contained this unusual element, for in the seat of honor beside the vice chancellor, were the master and certain members of the Court of the Grocers' Company, and the furs of city magnates were mingled with the plainer robes of the leaders of the medical world The occasion, therefore, had a special character on this account, but the story which Dr Wooldridge had to tell had an interest of its own, from the physiological point of view, and may come to have important practical applications in pathology The peculiar substance which he has isolated from the blood produces clotting within the vessels, with the most extraordinary rapidity, and it has already been found to be notably increased in quantity under certain diseased conditions Sir James Paget, in a few well chosen phrases, after the lecture, congratulated the Grocers' Company on the public spirit which they had shown in expending a thousand a year in the endowment of research No immediate practical application of Dr Wooldridge's observations was perhaps possible, but, said Sir James, when a scientific research comes to have a practical application, it ceases to stand in need of the generosity even of a rich city company —*Brit Med Jour*, April 17, 1886

Mr T Pridgin Teale on Fireplace Construction —The subject of firegrates may seem one somewhat alien to the surgical mind, but if the studies of Mr Teale lead to less poisoning of the atmosphere by the products of coal consumption, and to greater warmth of our houses in inclement weather like this, he will have earned the gratitude of the public and of invalids, and if he reduces the cost of coals by one-fourth, he will deserve the thanks of all who in these hard times have difficulty in making ends meet We shall best describe Mr Teale's views as to the principles of domestic fireplace construction by quoting his rules, which he states with great brevity, and which are as follows 1 As little iron as possible is to be used 2 The back and sides of the fireplace should be of brick or fire-brick 3 The firebrick back should lean over the fire, and not lean away from it 4 The bottom of the fire, or grating, should be deep from before backwards, probably not less than nine inches for a small room, or more than eleven inches for a large one 5 The sides or coverings of the fireplace should incline to one another, as the sides of an equilateral triangle 6 The lean over at the back should be at an angle of 70° 7 The shape of the grate should be based on a square described within an equilateral triangle, the size to vary in constant proportion to the side of the square 8 The slits in the grating, or grid, should be narrow, perhaps a quarter of an inch for a sitting room grate and good coal, and three eighths of an inch for a kitchen grate and bad coal When the slits are larger they allow cinders to fall through—in other words, waste 9 The front bars should be vertical, that ashes may not lodge and look untidy, narrow (perhaps a quarter of an inch in thickness), so as not to obstruct heat, and close together (perhaps three quarters of an inch apart), so as to prevent coal and cinders from falling on the hearth 10 There should be a rim an inch or an inch and a half in depth round the lower insertion of the vertical bars 11 The chamber under the fire should be closed by a shield or economiser 12 Whenever a fireplace is constructed on these principles, it must be remembered that a greater body of heat is accumulated about the hearth than in ordinary fireplaces, and corresponding care taken by an ashpan against heating wooden beams, etc This ash pan should have a double bottom, the space between the two plates being filled with artificial asbestos, slag-wood two inches in thickness 13 A fireplace on this construction must not be put in a party wall where there is no projecting chimney breast, lest the heated back should endanger woodwork in a room at the other side The benefits aimed at by Mr Teale are 1 Economy of fuel 2 Reduction of soot 3 Reduction of ashpit refuse Mr Teale astonished his audience by showing two small glass bottles containing the small ash residue of the coal burnt in his fireplaces, which consisted not of cinders, but very fine powder As to the saving of coal, the general manager of the Leeds Infirmary estimates that in that institution it amounts to a sixth or 100 tons in the year We have only space left to say that from some observation of Mr Teale's own fireplaces, and some experience of them, we believe he has got hold of the right principles and in a large measure of the details He was careful with the true candor of a scientific man to show how curiously his discoveries were anticipated last century by that remarkable man Count Rumford, who did study medicine, but, unlike Syme and Teale, drifted into other pursuits and was lost to the medical art —*Lancet*, February 13, 1886

Sanitary Inspection in Chicago —On April 9 Chief Inspector Genung issued the following order to the City inspectors regarding the inspection of tenements, and house-to house inspection of all the tenant or rental class of dwellings throughout the city

"Every inspection must include not only a thorough examination of all the conditions within the houses, but also the condition of the privies, cesspools, yard-areas, and spaces under the buildings and sidewalks, in fact, every part of any premises where it is possible for any thing of an unsanitary character to exist It is not enough that you simply point out these unhealthful conditions, but you must also cause them to be remedied at the earliest possible moment that the law will permit, as in the prompt application of these remedies lies the whole value of your labors Your work for the last year exceeded the previous one, as did all its predecessors, therefore, the present year should be no exception to the past, and must surpass all others in quantity and quality of work performed This can be readily accomplished if each inspector will do his full duty, as nearly all of you are well acquainted with all its requirements Neglect of duty and incompetency will not be tolerated, and while task-work is not demanded, yet, a reasonable amount of efficient work will be required from each of you It is wholly unnecessary to talk further upon this subject, as each of you knows precisely what your duties are, which, if well performed, will give us the best record in this kind of work on this continent" —*Sanitary News*, April 17, 1886

The Association of Surgeons of the Pennsylvania Company will hold its seventh annual meeting in Mansfield, Ohio, on Tuesday, May 18, 1886, commencing at 8 30 A M, standard time Several interesting papers are announced

The Sanitary Convention, announced last week as a "National Sanitary Convention," to be held in Philadelphia in May, will be held under the auspices of the Pennsylvania State Board of Health, and the word *National* was inadvertently printed on the circular

Alum in Baking Powders —In the official report of the Minnesota State board of health, for March 1886, is a report by Professor J A Dodge, of the University of Minnesota, of the analysis of seven samples of baking powder, the computation being made to anhydrous or "burnt" alum, without the water of crystallization Of the seven samples all contained alum, the amount ranging from 33 to 65 per cent Several analyses of "Snow Flake" and "Royal" baking powders have shown them to be entirely free from alum Prof J S Wood (Sixth Report Mass State Board of Health) says "The competition existing among manufactures of the better brands of baking powders, insures purity to a considerable extent, but the numerous cheap articles, the sale of which is promoted by the presentation of cups and saucers, tin spoons and other table ware, chromos, etc, are always suspicious and should be avoided on general principles The cheaper baking powders are more likely to contain alum than cream of tartar The latter substance is acid salt, which is most commonly used in the manufacture of the better brands The alum powders are condemned as unwholesome since the weight of evidence on the subject is to the effect that alum is not a proper substance to be used in baking bread"

Professor E G Janeway has been appointed to the Chair occupied by the late Dr Flint No more fitting appointment could have been made He will prove a most able successor to an extraordinarily able teacher

M Chevreul, "Doyen des Etudiants," the illustrious chemist and Academician, and the various learned societies of France propose to have a public demonstration in honor of the event

More Patients for Pasteur —The towns of Pullman and Kensington have sent three or four patients to Pasteur for prophylactic treatment against hydrophobia It was not entirely certain that the dog which bit the persons was mad, and all inquiries as to to the madness have been cut short by the shooting of the dog

Professor Ollier —A cable report announces the death of Professor Ollier, the distinguished surgeon, of Lyons The name is incorrectly spelled in the report, and it is sincerely to be hoped that the report is untrue

The Hydrophobia Commission —Sir James Paget, Drs Burdon Sanderson and T Lauder Brunton, and Sir Henry Roscoe, M P, will serve on the committee to inquire into Pasteur's method of innoculation for hydrophobia

The Academy of Medicine of Rome will send a delegate to Paris, to study Pasteur's method, of innoculation, and it is said that the German Government will send Drs Koch and Virchow for the same purpose Archduke Charles Theodore, of Bavaria, a practising physician will also go to Paris, to study Pasteur's method

Dr Edward Fournie, the distinguished laryngologist and aurist, and for a long time Director of the National Asylum for the Deaf and Dumb of France, and Editor of the *Revue Medicale*, died on March 24, aged fifty three years

---

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY, FROM APRIL 17 1886 TO APRIL 23 1886

Major M K Taylor, Surgeon, granted one month's leave of absence, on surgeon's certificate of disability, with permission to leave the limits of the Department (S O 39, Dept Mo, April 16, 1886)

Capt Wm W Gray, Asst Surgeon, ordered to Ft Maginnis, M T

Capt Ezra Woodruff, Asst Surgeon, ordered to Ft Missoula, M T

First Lieut Reuben L Robertson, Asst Surgeon, ordered for temporary duty at Ft Snelling, Minn (S O 33, Dept East, April 15, 1886)

First Lieut Philip G Wales, Asst Surgeon, granted leave of absence for one month (S O 56, Dept Columbia, April 8, 1886)

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U S NAVY DURING THE WEEK ENDING APRIL 24 1886

Lovering P A,, Past Asst Surgeon, ordered to Navy Yard New York

Biddle, Clement, P A Surgeon, detached from "Monocacy," ordered home and wait orders

Ames, H L, P A Surgeon, detached from Navy Yard, New York, and ordered to "Monocacy"

Crawford, M H, P A Surgeon, ordered to Naval Hospital at Washington

Hord, W I, Medical Director, U S N, and Medical Inspector J C Spear, U S, N, delegates to the meeting of the American Medical Association to be held at St Louis on May 5, 1886

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U S MARINE HOSPITAL SERVICE FOR THE WEEK ENDED APRIL 24 1886

Long, W H, Surgeon, granted leave of absence for seven days April 24, 1886

Banks, C L, Passed Asst Surgeon, granted leave of absence for ten days April 20 1886

Armstrong S T, Passed Asst Surgeon, granted leave of absence for five days April 20, 1886

THE

Journal of the American Medical Association.

EDITED FOR THE ASSOCIATION BY N. S. DAVIS.

PUBLISHED WEEKLY.

Vol. VI. CHICAGO, MAY 8, 1886. No. 19.

THE PRESIDENT'S ADDRESS.

Delivered before the Thirty-Seventh Annual Meeting of the American Medical Association, Tuesday, May 4, 1886.

BY WILLIAM BRODIE, M.D.,

OF DETROIT, MICH.

GENTLEMEN OF THE AMERICAN MEDICAL ASSOCIATION.—With great pleasure I congratulate you on your coming together to renew old friendships, to make further acquaintances, and to add to the general storehouse of medical information, thus demonstrating to our fellow-citizens that the medical profession are not only interested in its own welfare, but also in theirs.

We have reason to be thankful to the Supreme Ruler of the universe that no epidemic disease has devastated our land, and, with but few local exceptions, that a general state of health has existed. We have also to be thankful that so many have been spared to again meet in council and demonstrate our vitality as an association. Yet with all these blessings showered upon us, Death has been within our ranks, and some of our honored ones have yielded to his sceptre. It is, therefore, with sadness that I refer to the decease of Drs. W. K. Bowling, of Nashville, Tenn., John L. Atlee, of Lancaster, Penn., and Austin Flint, Sen., of New York City, during the past year, ex-Presidents of this Association.

Dr. Bowling first identified himself with the Association in 1853, and from that time to his death was one of its firmest friends. In 1851 he founded the "Nashville Journal of Medicine and Surgery," which he sustained for a quarter of a century. The same year he assisted in founding the Medical Department of the University of Nashville, and was elected Professor of Practice and Institutes of Medicine. Deeply interested in public education, in 1853 he delivered the oration upon the occasion of laying the corner stone of the first public school building in Nashville. In 1856 he was elected Third Vice President of this Association. In 1861, he was sent as peace ambassador from the State of Tennessee to the Governor and Legislature of Kentucky. In 1867 he was elected First Vice President, in 1873, President of the Association of Medical Editors, and in 1874, President of the American Medical Association.

His contributions to medical literature are to be found in the journal of which he was editor. He was never negative, but always positive in the views and opinions he advanced. In 1876, he was appointed by his State a member of the International Medical Congress of 1876, which met in Philadelphia.

As an editor, it was said of him, he never kept his printer waiting for copy or money, and the greatest living medical critic said of him in his journal: "A man of genius as well as learning, of the true poetic temperament, he has written some of the most brilliant articles in our medical annals."

He was a scholarly man and a beloved physician. As a teacher he was worshipped by his classes, and when declining years warned him of his approaching end, he retired to his summer home, Monteagle, in the Cumberland mountains, for rest and recreation. But so devoted was he to his profession that the sufferings of a little child appealed to his benevolent heart and was his last patient. He died as he had lived, a noble, generous hearted man, loving his profession and his God.

John Light Atlee. We find his name first registered in 1848, as a delegate from the Medical Society of the State of Pennsylvania. From that time to his elevation as president, in 1882, he was in almost constant attendance upon its meetings and was always one of its firmest supporters.

The code of ethics was to him as an injunction from the *Most High*, and he considered this Association as the embodiment of perfection.

In 1820, at the age of 21 years, he commenced the practice of medicine in his native town, where he resided until his death, October, 1885.

Surgery was his element, and in this department of medicine he achieved his reputation. He was prominent as one of the pioneers in this country for the successful operation of ovariotomy. This alone entitles his memory to a grateful recognition by the American medical profession. My first acquaintance with him began in 1856, when he took an active interest as a delegate from his native city. He was a tall, slender looking man, with a clear and expressive countenance indicative of firmness and confidence in the truth of his convictions, ardent in the pursuit of knowledge, he was neither obsequious to men nor submissive to opinions which he thought hostile to the best interests of his profession. He was opposed to anything that savored of quackery, and believed that medicine was a science, and based upon fundamental principles.

He was a physician in the widest sense of the term, taking an interest in every department

He had the confidence of the profession in his home and the State of Pennsylvania, as evinced by his large consulting practice

He left a record of 2,125 important surgical operasions, and attended 3,264 cases of parturition, all independent of hospital or college connection, and were exclusively private

His practice embraced a period of 65 years, and continued till a few days before his death Though advanced to his 86th year, he retained the vigor of manhood to such a remarkable degree as to appear to strangers as a man of only threescore years and ten Of him it can be said, correct business habits enabled him to accumulate a handsome fortune At the same time, he did a large amount of unrequited and benevolent labor Not unmindful of his honor as a man, he never sought to enhance his own popularity by depreciating that remuneration for services o which every honorable physician is justly entitled

Dr Atlee was a constant and devoted member of the Episcopal church, and adorned the doctrine he professed with reverent acknowledgment and an abiding faith He came to his "grave in full age, like as a shock of corn cometh in its season "

Austin Flint, Sen , died March 13, 1886, at his residence in New York City, of cerebral apoplexy He was one of the founders of the Association, being present as a delegate from the Erie County Medical Society of New York, at the initial meeting in 1847 He was then appointed one of the committee "Upon a uniform and elevated standard of the requirements for the Degree of Doctor of Medicine by all the Medical Schools of the United States" This report was exhaustive on the subject, and the resolutions appended, with only one slight amendment, were unanimously adopted, and laid the foundation of the advanced requirements of the present day

During his membership, he gave several valuable papers to the Association Among the most prominent were those on Practical Medicine, Materia Medica and Physiology, Cerebral Symptoms in Heart Disease, Clinical Study of Heart Sounds, Pathology of Diabetes, Typhoid Fever, and Variations in Pitch in Percussion His Address on Medicine and Medical Progress in the United States, before the International Medical Congress of 1876, in Philadelphia, and his address as President of the Association, in 1884, were especially able In the latter address he presented the suggestion of inviting the Ninth International Medical Congress to meet in this country, at its Capitol, Washington

From his youth up, Dr Flint was an indefatigable laborer in the field of medical science His reputation as a teacher and author was world-wide Conscientious in his relation to the profession he so fondly loved, and to the public, his recognition of the code of ethics, as exemplifying the honorable relations of the profession towards one another and to their constituents, elevated him to the position of the true gentleman

In his death we have lost a bright star, and the International Medical Congress, for which he was selected (I may say unanimously) as its presiding officer, must mourn his sudden demise Few men have been so justly eminent and yet so widely beloved and admired His works are the expression of his experience and observation, and have been received by his professional brethren, not only at home, but abroad, as standard authority The British Medical Association was honored by his acceptance of their invitation to deliver the address on *Medicine* at their next meeting, thus demonstrating the appreciation with which he was held abroad With such a reputation as he had achieved, it may well be said, "To die is noble"

The past generation of the great men of our profession are fast fading away The seats they have so honorably filled in this Association are becoming vacant—may we indulge the hope, to be again filled by those of the present, who will so well represent their honor and professional integrity, that future generations may say of them, their mantle has fallen upon deserving merit

It is my purpose in addressing you at this time to confine myself chiefly to matters pertaining to the progress, interest and welfare of this Association Although I may seem to tread in the footsteps of my predecessor, Dr Flint, in his address at Washington, and the subject may seem familiar, yet I have an entirely different object in view[1]

When the first National meeting of the profession, under the call of the New York State Medical Society, was held in the city of New York, May 5, 1846, Dr I Hays, of Philadelphia, moved, and it was resolved, "That it is expedient for the medical profession of the United States to institute a National Medical Association for the protection of their interests, for the maintenance of their honor and respectability, for the advancement of their knowledge and the extension of their usefulness" Upon this broad foundation has arisen the largest representative medical association known in history

At this gathering 120 medical men met in consultation They fully endorsed the resolutions presented by Dr Hays, they also recognized the necessity of a united profession, and in order to attain this great end they resolved that a committee of three members should be appointed to report a plan of organization at a future meeting to be held in Philadelphia the first Tuesday in May, 1847

They also recognized that a uniform and elevated standard of medical education should be adopted by all the medical schools for the degree of M D in the United States, and to properly present this question to the profession and the schools they appointed a committee to report at the same time

They also recognized the fact that men were being educated who had received no suitable preliminary training, and they appointed a committee to report a standard of requirements which should be exacted of such young men as purposed entering upon the study of medicine

---

[1] See Organization American Medical Association Preliminary Volume

They also recognized that principle was one thing and conduct another, and that the *Golden Rule*, however sound and correct, failed in practice, that, however good the intention, experience had shown that written rules and regulations were of much more binding force than abstract reasoning and even Divine Law They therefore deemed it essential that the entire medical profession in the United States should be governed by the same code of ethics, and to that end a committee was appointed to report

The question of the union of teaching and licensing in the same hands was also considered It was believed to be wrong in principle and liable to great abuse in practice Instead of conferring the right to license on medical colleges and State and county medical societies (as was then the custom), it was deemed best that it should be restricted to one Board in each State, a principle now fully recognized, and practically carried out, by the State of Illinois This was also referred to a committee to report

The subject of urging upon the several State governments the adoption of measures for a registration of marriages, births and deaths, was favorably considered, and referred to a committee

They also considered the necessity of a proper nomenclature of diseases, adapted to the United States, with reference to a general registration This was also referred for report

According to the best information I can obtain, only four of these pioneers of this Association are now living To them this Association owes a debt of gratitude which can never be paid Of these four, two have been honored by the Presidency—Dr A Stillé and Dr N S Davis Drs Alonzo Clark and Lewis P Bush are the other two All have reached their three score years and ten

The convention of 1846 adjourned to meet in Philadelphia May 5, 1847 Twenty two States and the District of Columbia were represented at that meeting by 247 delegates Considering the modes of traveling at that day it was a large representation of the profession of our country, and again showed the interest in the organization of this Association At this meeting the report of the committee on the organization of the American Medical Association was adopted, Dr John Watson, of New York, chairman, and, what is remarkable, stands with but slight changes as the present constitution

The report of the committee upon a uniform and elevated standard of requirements for graduation in medicine, which was adopted, called the attention of the profession to the necessity of a more rigid examination and a higher degree of preliminary education The Educational Department at once recognized the value of the suggestion, and to day we find the medical schools giving more attention to the quality of their graduates than to the numbers of those who receive from them the degree of M D

The report of the committee on preliminary education aroused the attention of both the private preceptors and the medical schools to the deficiencies of young men desirous of entering the profession The time had come when the demand for medical men with a modicum of preliminary education was less than the supply By means of the system of common schools, academies, colleges and universities, the people themselves were more highly educated Men entering into the learned professions readily observed that, in order to gain the respect of their patrons who were educated, they themselves must also be educated This report at once gave a stimulus in the proper direction, and from that day to the present, preliminary acquirements of a higher standard are required by all medical colleges which have any regard for the standing of their graduates Education is the requisite of a gentleman, and no one should be allowed to enter the portals of the medical profession who has not that qualification

The committee, under the resolution that it is expedient that the medical profession should be governed by the same code of medical ethics in this country, founded their report on the "basis of religion and morality," which comprised not only the duties but also the rights of a physician The high character of that committee, their age and experience, fully qualified them for the delicate duty imposed upon them Time has fully proved the wisdom of that report

The Code of Ethics as adopted has stood the test of nearly forty years, and for more than nine-tenths of the regular medical profession of these United States constitutes their rule of action and professional government

Even those styling themselves eclectics or homœopathists, have copied its principles in their constitutions and made it the basis of their relations to one another and to the public The government of the United States is based upon a written constitution, States and municipalities are governed by the same principles The doctrine of majorities as thereby inculcated governs the action of organized society in its minute ramifications, the medical profession is no exception We meet here to day upon this broad principle, and what is most remarkable, of every State Medical Society county society, or local organization which has adopted the Code, only one has repudiated it and entered upon the rôle of a *solitary minority* I allude to the Medical Society of the State of New York, from which came the invitation, in 1845, for the preliminary meeting that gave birth to this Association

To their honor be it written, the majority of the profession of that great State repudiated the action of their State Medical Society, and it now has the unenviable position of being solitary and alone in its opposition to the Code of Ethics The reason for this defection was so manifestly financial that its influence did not extend beyond its own jurisdiction It is through its Code that this Association represents the whole body of the medical profession throughout these United States, as the American Congress represents the people of the same

Could those wise men who framed this Code be here present with us to day in this hall and witness your presence, they would say, like one of old, "Now lettest thou thy servant depart in peace" But one of that committee is now living[1]

---

[1] Alonzo Clark M D New York City

In no one subject are the people of our country more interested than in that of medicine, and no profession is more respected.

Educated as the large majority of them are, they fully comprehend the relations of the profession. They are independent thinkers, and in their relation to the profession cannot be bought or sold. How wide the difference between this country and Europe! There a practice can be bought and sold, here a transfer is of no value because there can be no delivery.

It has been charged that this Association has failed to meet the requirements of its founders, and instead of being a body for the advancement of scientific medicine has degenerated into a body of "thankless intriguers and demagogues."[1] For thirty-nine years this Association has been in existence. At its organization no other National association of medical men existed.

A few of the older States had their State societies. The county societies in those States were few and far between. In the larger cities local societies were maintained, each was independent of the others. There was no general forum where individuals could present their investigations, and when presented, no general means of their dissemination. Could the transactions of this body be critically analyzed, the charge that scientific medicine has not been advanced by its existence would lamentably fail.

The character of the work done by the Association since its organization may be well exemplified by a few selections from its Transactions.

The essay of Dr. Dalton on the Corpus Luteum in Pregnancy gave him a National reputation as a physiologist.—*Vol. 4.*

The prize essay of Dr. Austin Flint, Sr., on the Value of Pitch in Percussion, and Respiratory Sounds and their Application to Physical Diagnosis, opened a new era in the investigation of pulmonary diseases.—*Vol. 5.*

Coxalgia or Hip Disease, by Alden March, M. D., an ex President of this body, gave the first impulse to the proper diagnosis of this disease, and its treatment.

The prize essay of Prof. Charles D. Meigs, on Acute and Chronic Diseases of the Neck of the Uterus, laid the foundation of the department of gynecology, and the plates illustrating his cases are copied to the present time.

The Surgical Treatment of certain Forms of Fibrous Tumors of the Uterus, by Washington L. Atlee, M. D., opened the field for the ovariotomist.

The Cell—its Physiology, Pathology and Philosophy, by Waldo I. Barnett, from original investigations, anticipated Virchow.—*Vol. 6.*

The new method of treating Ununited Fractures and Certain Deformities of the Osseous System, by Daniel Brainerd, would have done credit to Malgaigne.—*Vol. 7.*

Deformities after Fractures, by Dr. F. H. Hamilton, has become authority at home and abroad.—*Vol. 8.*

Statistics of Placenta Prævia, by Dr. J. D. Trask.—*Vol. 8.*

The Clinical Study of Heart Sounds, by Austin Flint, Sr., M. D.

The Physiology of the Arterial Circulation and the Chief Pathological Relations, by Dr. H. Hartshorne.—*Vol. 9.*

Report on the Nervous System in Febrile Diseases, and the Classification of Fever by the Nervous System, by Henry Frazer Campbell, M. D., indorsed by the late Marshall Hall.—*Vol. 10.*

Report on Moral Insanity and its Relation to Medical Jurisprudence, by D. Meredith Reese, M. D.—*Vol. 11.*

Report on a Uniform Plan for Registration of Marriages, Births and Deaths, by W. L. Sutton, M. D., laid the foundation for such record.—*Vol. 12.*

Report on the Influence of Alcoholic Drinks in the Development and Progress of Pulmonary Tuberculosis, by N. S. Davis, M. D.—*Vol. 13.*

Report on Morbus Coxarius, or Hip Disease, by L. A. Sayre, M. D., illustrative of the fixed treatment by Plaster of Paris.—*Vol. 13.*

Prize essay on the Pathology of Jaundice, by S. Fleet Speer, M. D.—*Vol. 13.*

Prize essay on the Criminality and Physical Evils of Forced Abortion, by H. R. Storer, M. D.—*Vol. 16.*

Prize essay on the Surgical Treatment of Morbid Growths within the Larynx, by Louis Elsberg, M. D., the father of laryngoscopy.—*Vol. 16.*

Report on the Etiology and Pathological Relation of Epidemic Erysipelas, Spotted Fever and Diphtheria, by N. S. Davis, M. D.—*Vol. 17.*

Report on Plaster of Paris in Surgery, by James L. Little, M. D.

Prize essay on the Treatment of Certain Uterine Abnormities, by Montrose A. Pallen, M. D.—*Vol. 18.*

Report on the Best Treatment for Different Forms of Cleft Palate, by W. R. Whitehead, M. D.—*Vol. 20.*

Mollites Ossium, by Joseph Jones, M. D.—*Vol. 20.*

Prize essay on the Treatment of Aneurisms, with Experiments for the Closing of Arteries by a New Method, by Benj. Howard, M. D.—*Vol. 21.*

Prize essay, Atropia and its Salts, by Roberts Bartholow, M. D.—*Vol. 20.*

What Physiological Value has Phosphorus as an Organismal Element? Prize essay by Samuel R. Percy, M. D.—*Vol. 23.*

Syphilis in its Relation to the National Health, by S. D. Gross, M. D., LL. D., Oxon.—*Vol. 26.*

A Discourse on Blood Letting, the Lost Art, by S. D. Gross, M. D., LL. D., Oxon.—*Vol. 26.*

History of Yellow Fever and Dengue in Texas, by Greenville Dowell, M. D.

Excision of Large Joints of the Extremities. A prize essay by H. Culbertson, M. D.—*Supplement to Vol. 27.*

Report on Animal Vaccination, by H. A. Martin, M. D.—*Vol. 28.*

Prophylaxis of Septicæmia in Surgery, by E. M. Moore, M. D.—*Vol. 29.*

Surgical Anatomy and History of the Common External and Internal Carotid Arteries, Anatomy and History of the Innominate and Subclavian Arteries. A prize essay by John A. Wyeth, M. D.—*Vol. 29.*

The Pathology of the Bones, by Henry H. Smith, M. D.—*Vol. 29.*

---

[1] New York Medical Journal, page 44, 1885.

Blepharoplastic Operations, by A C Post, M D —*Vol 29*

Prize essay Consideration of Certain Forms of Primary and (Local) Secondary Degeneration of the Lateral Columns of the Spinal Cord, etc , by Allan McLane Hamilton, M D —*Vol 30*

Treatment of Fibroids of the Uterus by Means of Dry Earth, by Addinel Hewson, Sr , M D —*Vol 31*

Progress in the Knowledge of the Acute Contagious Diseases and Infection, by A Jacobi, M D

Fibroid Tumors of the Uterus, by H O Marcy, M D —*Vol 33*

These papers fully illustrate the character of the work done by the Association since its organization Besides the reports on Medical Education, Medical Literature, Registration of Marriages, Births and Deaths, Medical Jurisprudence, Hygiene and Insanity, Meteorology and Epidemic Diseases, Cryptogamic and Zymotic Diseases, Practical Medicine, Materia Medica, Physiology, Obstetrics and Diseases of Women and Children, Surgery and Anatomy, Chemistry and Psychology, Pediatrics, State Medicine, etc , scarcely a question of importance, whether in the interest of the profession or the public, has failed to receive investigation

Before the time of this Association, specialties in medicine were unknown All medical men were general practitioners The prominence given special diseases by its reports and investigations led men to give special attention to particular diseases The accretions of people in the larger cities developed the field for a division of general practice, and the selection of a particular branch of disease, applicable to a particular organ, was soon found to be remunerative and less toilsome The advance of time developed the number of specialties The first to organize a National Association were the Ophthalmologists, the leading specialty, then followed the Otologists, Gynecologists, the Dermatologists, State Medicine and Hygiene, under the name of Public Health, the Laryngologists, the Surgical Association, and latest, the Association of Physicians and Pathologists Some of these Associations are necessarily limited in number others have specified their limitation All are off shoots of this Association Each occupies a limited territory The American Medical Association covers the whole field of medicine, and through its Sections affords an opportunity to every member, whether high or low, to give to the profession any and all of his personal knowledge

> "No pent up Utica contracts its powers,
> The boundless universe of Medicine is ours "

The course of events in science, as well as in medicine (and I use the latter term in its broadest sense), demonstrated that much which is called new has had its expression in the writings of the fathers, and experience has shown that change is not always progress

The prevention of yellow fever, the scourge of the Gulf States, is a problem in which our whole country is interested Dr Joseph Holt, of New Orleans, President of the State Board of Health of Louisiana, has given much time and study to this question A bill has been reported in the House of Representatives, at Washington, appropriating money to investigate whether it can be aborted and even prevented

A proper resolution adopted by this body, approving such a bill, would have great weight with Congress It is highly proper that all such investigations should be conducted at the expense of the general government

A series of resolutions were adopted by this Association at the meeting in Atlanta, Ga , on the metric system, which have been a dead letter in the Transactions ever since The several State Medical Associations, which at that time also approved the system, have never applied it in their Transactions Only a few of the profession follow it in writing their prescriptions, and with rare exceptions it is not used by writers on medicine Dr Oldberg, through whose influence while medical purveyor in the United States Marine Hospital Service it was introduced, has declared it a failure I would therefore recommend that it be stricken out of the list of ordinances

The value of the Sections has been so fully proven that I would recommend that in addition to the proposed new Section of Medical Jurisprudence, one on Dermatology and Syphilis be added

The work in the Sections depends so much upon the efficiency of their officers, the Secretary in particular, and as permanency adds to efficiency, I would recommend that the Secretaries of Sections be made permanent, subject to removal on the recommendation of the Section The wisdom of such permanency can be readily comprehended

In imitation of the British Medical Association, the journal system was adopted I take great pleasure in stating that thus far it has been a satisfactory success The Board of Trustees, with its efficient Editor-in chief, have so managed its finances that it has proved no incumbrance on the Association The plan adopted of receiving members by application, has proved satisfactory, not only by increasing the circulation of THE JOURNAL, but also by increasing its emoluments The report of the trustees will give you a full and explicit statement of its financial condition and its growth

I would also call the attention of the members of the Association to paragraph 3 sec 4, of the by laws "Every paper received by this Association and ordered to be published, and all plates or other means of illustration, shall be considered the exclusive property of the Association, and shall be published and sold for the exclusive benefit of the Association "

As this by-law makes all addresses, papers and reports presented to the Association, or in its Sections, the exclusive property of the Association, it is not proper to give copies of such addresses to other journals to appear entire before or simultaneous with their appearance in THE JOURNAL OF THE ASSOCIATION If the proprietors of other journals choose to employ competent reporters to secure such reports and abstracts of your proceedings, either in the general session or in the Sections, I would place no obstacle in their way But if they wish to use papers in full, let them copy the same from the official organ of the Association, giving proper credit therefore And every member of the Association should have sufficient interest in sustaining THE JOURNAL that it has established, to comply fully with the by law I have quoted

I respectfully call your attention, and through you that of the medical profession at large, to the last paragraph of sec 2, art 1, "Duties for the Support of Professional Character," Code of Ethics, to wit "It is also reprehensible for physicians to give certificates attesting the efficacy of *patent* or secret medicines, or in any way to promote the use of them" The fact that proprietary medicines were not included in this paragraph has left the door wide open for the greatest abuse and injury both to the profession and the public Practically there is no difference between a patent medicine and a proprietary one In the former the constituents are not known, and although given in the latter, there rests an ownership in their combination that prevents them being compounded by others Professional men of high repute who lend their names as endorsers to any proprietary medicine should be looked upon by the profession as aiders and abettors, and should be proper subjects for discipline in any honorable medical society It is one of the crying evils of the day, and does injury both to the profession and to the public

The stigma of professional disgrace should rest upon any regularly educated physician who allows his name to be advertised as the endorser of any patent, secret or proprietary medicine

The British Medical Association is peculiar in its organization, consisting of the parent stem and its branches It has been suggested that this Association be modeled upon the same plan, by the formation of branches in the different States and Territories

Upon a careful examination of the Constitution of the British Association and its branches, I am unable to discover any superiority to that of this Association and its affiliations

In practical application our own system meets the same ends Late leading articles in THE JOURNAL OF THE ASSOCIATION have so well discussed the question that it needs no further elucidation from me However, its reference to a committee to report next year might be profitable, as any information or change that can add to the improvement and advantage of the Association should be adopted

It is with great pleasure that I am able to inform you that the action taken at the meeting in Washington, inviting the Ninth International Medical Congress to meet in the Capital City of the United States in 1887, is being fully consummated The general officers of the Congress and Council, and the officers of the Sections, are gentlemen of renown in our own country, who add lustre to American medicine Full and complete arrangements will be made for the meeting, and our foreign friends will receive a cordial welcome Upon the reception of the report of your committee on the preliminary organization of the Congress, I believe you will find it satisfactory, and upon its adoption the further charge of the Congress will pass into the hands of the Executive Committee, as provided in Rule 10, thus relieving this Association of its responsibility in the matter

As the authority of this body to act for the medical profession of the United States has been questioned, it may be proper for the information of many of the members to briefly present, in a concise manner, the relations of the Association to the coming International Congress

A Medical Congress to be International must necessarily be composed of members from different nations Eight of these Congresses have been held in Europe, if we may except the International Medical Congress held in Philadelphia, September 4, 1876, the last of which was held in Copenhagen, Denmark

At the meeting of this Association in Washington, D C, in May 1884, the President, Dr Austin Flint, Sr, suggested the propriety of inviting that body to meet in this country The suggestion was referred to a committee who reported favorably A committee was appointed to present the invitation This committee was made broad so as to represent the whole profession of the United States The invitation was accepted This committee was further authorized, in the event of the invitation being accepted, to add to their numbers, and proceed to perfect an organization with rules for its government This the committee did in accordance with custom and the rules governing the action of committees This committee made its report to this Association at its next meeting, which was in New Orleans, the 28th day of April, 1885 By this action of the committee they fully recognize their responsibility to this body, and not to the profession at large

This report was not satisfactory, and the committee was enlarged by adding a member from each State and Territory, the Army, the Navy, and Marine Hospital Department To this action the original committee demurred, and declined to take any further interest in the arrangements That the Association was correct in its action I have only to refer you to *Cushing's Manual of Parliamentary Law*, the authority in this country, page 154, paragraph 262 When this committee made their report, and it was accepted, the committee was virtually discharged, (page 168, paragraph 290) The report was not adopted What had passed in the committee was of no validity It was in the power of the Association to discharge the committee from further consideration of the subject, to refer it back to them with instructions, or to enlarge the committee The latter plan was adopted

It was claimed that there was an ambiguity in the resolution appointing the original committee in reference to their powers and duties Whatever that ambiguity was, the committee itself settled the question by making their report to the Association, thereby acknowledging the authority of their powers and duties

I cordially unite with the general sentiment of the medical profession that the report of your committee be adopted, and that those of our brethren who may be somewhat disappointed at results will yield their personal feelings to the common good, and by their work demonstrate to our foreign friends that, although there have been warm feelings, warmly expressed, they can rise above their personalities in the great question of Medical Science and National Hospitality

Gentlemen, matters of importance arising out of the ordinary proceedings of this Association may come before you at this meeting, and questions may arise affecting its honor and integrity. Even the existence of this Association, so dear to the hearts of the medical profession of these United States, may be hazarded. Upon you as its representatives will rest its preservation. Thirty-nine years of existence has entitled it to your support. Its work and beneficent influences are on record, and speak for themselves. May I ask of you, as its President, to give careful consideration to any and all matters that may affect its interest and permanency, so that when you return to your constituency you can tell them that, although the Association has been attacked by foes within and foes without, it yet stands as the representative of the American medical profession.

In conclusion, may I kindly ask of you the amenities due to the office to which you have so kindly promoted me, and your cordial support. It shall be my endeavor to be impartial, and to perform the duties of the chair according to strict parliamentary rules.

The honor of being elected by you as President of the American Medical Association is one that words cannot express. For thirty-two years I have, whether present or absent, had its interests deeply at heart, and when my term of office expires I will gladly return to the ranks with the same zeal for its interests which I felt when I first became a member in this great city of the south-west, St. Louis, Missouri, at the meeting of the Association here in 1854.

ORIGINAL ARTICLES.

TWO CASES OF REFLEX PARAPLEGIA (ONE WITH APHASIA), FROM TAPE-WORM AND PHIMOSIS.

BY WM. G. EGGLESTON, M.A., M.D.,

OF CHICAGO, ILL.

The existence of a "reflex paralysis" was denied about two years ago (May, 1884) by Dr. C. J. Nixon in a paper read before the Academy of Medicine in Ireland. Dr. Nixon's paper was to the effect that the cases of paralysis of which amaurosis from affections of the fifth nerve, and paralysis of the orbital nerves from a like cause, are examples, may be explained without reflex mechanism. As regards the views of Brown Séquard, Gull, Leyden, and others, and the experimental observations on the subject, he said that there was no true conception[1] of the mode in which paralysis by reflex action is brought about, unless we understand it to be produced by inhibitory influence; so that reflex paralysis, if it have any meaning, must be inhibitory paralysis. He thought that there is no necessity of admitting the existence of an inhibitory paralysis as, taking for example the cases recorded as reflex paralysis, they could arise in different ways—as an ascending neuritis, which sets up myelitis from extension along the veins[2] to the spinal cord, or from a lumbo-sacral neuritis, which descends along the sciatic nerves. He held that the cure of a paralysis by such a simple procedure as lancing a gum was a physical impossibility. It is particularly to be noticed that though he said he had never seen a case of reflex paralysis, he quoted examples of *inhibitory* nerve influence, which he says is another name for reflex paralysis!

At the meeting at which this paper was read Dr. Kennedy opposed Dr. Nixon's views, as did others, and stated that he had seen several cases of arm-paralysis from gingival and intestinal irritation, the paralysis disappearing on the removal of the irritation. Two or three years ago Dr. Gomez Torres reported the case of a woman with paralysis and atrophy (partial?) of the upper extremity. Examination showed a chronic parenchymatous metritis and extensive ulceration of the cervix. She began to improve almost immediately under proper treatment for the uterine affection. Frankel has recorded a case of hemiplegia due to indigestion. In the *Journal de Medecine et de Chirurgie Pratique*, September, 1884, are recorded three cases of aphasia from indigestion. A boy, 3 years old, was aphasic for two hours, and recovered after vomiting; a little boy was aphasic for a day, and recovered after vomiting; a little girl was aphasic for about a day and recovered in the same way. The two cases which follow may, I think, be regarded as undoubted examples of reflex or inhibitory paraplegia.

Case 1.—Reflex Paraplegia and Aphasia from Tape-worm.—In July, 1884, a woman brought her little girl, æt. 6 years, of German parentage, to my office (in Philadelphia). The child had been under treatment in one of the dispensaries for five weeks for spinal disease. It was taken to the dispensary on the day after its illness became markedly prominent. The symptom first noticed was inability to speak, and on the next day it was unable to walk. Previous to this the child had not been sick since its second year, though it had frequently complained of its stomach. There had been no vomiting, and no diarrhœa. The mother stated that there had been no difficulty in swallowing at any time, and the child's appetite was enormous. It had no difficulty in putting out its tongue, voluntary movements of the upper extremity were normal, and the pupils were normal. The vesical and rectal sphincters were under control.

Physical examination showed entire absence of painful spots along the spine, absence of cardiac disease, a rather marked enlargement of the abdomen, and no anæsthesia, rigidity or atrophy of the paretic legs. The patellar reflexes were normal. In testing for anæsthesia I drew a pencil along the anterior aspect of one leg, and found, to my astonishment, that a white line was produced. The same line was produced by irritation of the other leg. This convinced me that the paraplegia was not due to spinal disease, in which irritation produces a red line. In the erect position the child was utterly unable to move the legs, while in the recumbent posture it could draw them up with apparent ease; facts which at once recalled the remarks of Romberg[1] on reflex paralysis from intestinal irritation. The fact that the child had for some time prior to its illness eaten raw meat with its parents, and the further fact that there was a condition of marked pruritus at either end of the alimentary tract, caused me to make a temporary diagnosis of tape-worm

---

[1] Abstract in The Lancet, August 23, 1884.

[2] A way of transmission supposed by Gull.

[1] Diseases of the Nervous System, Sydenham Edition, 1853.

I instructed the mother to give only milk for the child's supper, and to give two teaspoonsful of spirits of turpentine at 6 A M, with the same quantity of milk, two at 8, and two at 10 with a tablespoonful of castor oil The mother was to report if the turpentine caused any unpleasant effects

On the day after the turpentine was administered the mother brought me a bottle containing a tænia solium, five feet and a few inches long, with the head The tænia was passed about noon, two hours after the dose of castor oil was given It was the ordinary pork tape worm—tænia solium, as stated above

The patient did not speak or walk until the morning after the tænia was evacuated There was then no difficulty in articulation, nor did it seem to have forgotten its ordinary vocabulary The power over the legs was not so suddenly acquired, but when brought to my office two days afterwards there seemed to be no difficulty in locomotion

Here was a case of simple paralysis of the lower limbs, of two months' duration, sudden onset, accompanied by aphasia, neither of which were intermittent, and evidently in no way connected with chorea, without sensory trouble, or want of control over the bladder and rectum It seems in the highest degree improbable that either of the troubles for which she came under treatment could have been due, as Dr Nixon thinks, to an ascending neuritis—as improbable, in fact, as that the twitching of the eyelid so frequently seen in dyspeptic cases should be due to a sudden neuritis, which disappears equally suddenly This is more especially true of the three cases cited above from the *Journal de Medecine de Paris*

Case 2 —Reflex Paraplegia and Strabismus from Phimosis—On January 3, 1886, I was called to see E K, æt 3 years, a poorly nourished boy, of rather rachitic appearance The mother said that he had never walked as well as he should for his age, and that for two weeks the power over the lower extremities had decreased very rapidly until it was noticed on January 2 that he could not walk at all Two days before this it was first noticed that his eyes were strabismic—alternately convergent and divergent The father was a traveling man, and the boy had been under electric treatment in Kansas City for a week before coming to Chicago

On examining the patient I at once discovered that there was a considerable degree of phimosis, with two adhesions In the recumbent posture he could draw the legs up with much difficulty, but when erect he had no power over them There was no anæsthesia, no tender spots along the spine or elsewhere The patellar reflex was normal The rectal sphincter was under perfect control, but there was some loss of power over the vesical It was easily seen that the strabismus was alternately convergent and divergent Remembering the white line produced by irritation of the skin in Case 1, I found that the same thing occurred in this case [1]

Three drops of an eight per cent. solution of cocaine were injected between the glans and foreskin, and the adhesions were easily and painlessly ruptured within two minutes The line of operation was then marked out, the foreskin drawn forwards and caught in a pair of padded forceps, and three drops of the cocaine solution injected into the foreskin at different points The forceps were then gradually tightened in order to prevent the cocaine gaining access to the general system and possibly causing evil effects Two minutes after the injection there was no sensibility to a needle run through the foreskin, and it was then severed The cocaine solution was then applied locally around the corona, and the operation was leisurely completed without a cry from the patient

The operation was performed late in the afternoon, and it was not hoped that any result could be seen until the following day On the next morning the strabismus was only slightly noticeable, and it passed away entirely within forty eight hours after the operatian The patient was kept quiet for three days on account of the operation When he got up he could walk fairly well by supporting himself with a chair As he had never walked well it was not to be hoped that locomotion would be very good until after the lapse of several weeks He was put on tonic treatment, and his father left Chicago ten days after the operation On April 17 he wrote from Omaha that his son walked easily without support, that there was no squint, and that his general health was very much better

Mr D Corbett, of Dublin, has reported[1] the case of a girl, æt 7, whose condition was described by her father, a medical man, as follows "Nothing unusual in her condition since birth was observed, until within a period of two years, when weakness of the lower extremities showed itself, accompanied with occasional impairment of vision This state of things gradually grew worse, until the power of progression was quite gone, unless assisted, and there was complete loss of vision when she assumed the erect from the sitting posture, though in the latter she could distinctly see large objects" Mr Corbett found incompletely ruptured wisdom teeth in the lower jaw, and giving unmistakable evidence of severe pressure against the second molar to the extent of slight lateral displacement downwards The second molar on each side was extracted Slight improvement was noticed in a week, and three months afterwards all constitutional disturbance had disappeared, except that vision in the right eye was lost

McKendrick[2] has reported the case of a woman, aged 29, who had suffered for seven months from a partial paralysis of the lower limbs, with normal sensibility She passed a tape-worm nearly twenty two feet long, and four days afterwards had completely recovered the use of her limbs Fuller[3] has reported the case of a boy, 3 years old, who had paralysis first of the right leg, and then of the left Immediate improvement followed a dose of santonine, which brought away fifty-three dead lumbricoid worms

---

[1] Unfortunately it did not occur to me in either case to test the skin of the unaffected portion of the body

[1] Transactions Seventh International Congress iii, 474

[2] The Lancet Vol II 1865

[3] Lancet Vol II 1866

Moll[1] reported the case of a woman who suffered for three months from paralysis of the upper extremities All the symptoms disappeared immediately upon the expulsion of a tape worm

The number of cases reported in which recovery has followed immediately upon removal of the irritation is too large, though the number may be absolutely small, to admit the idea of organic spinal lesion In some of the cases of peripheral paralysis reported by Mitchell, Keen and Morehouse, for example, the paralysis in the parts supplied by one nerve followed injury to another nerve too soon to admit of any anatomical lesion In many cases the paralysis can be explained in no other way than as a reflex inhibitory action Echeverria reported, in 1863, a case of paraplegia of the lower extremities caused by the application of electricity to an ulcerated os uteri The paraplegia disappeared in fourteen hours Nonat[2] published a case of loss of consciousness and paraplegia due to cauterization of the cervix uteri Landry reported a case in which paralysis disappeared after restoration of a deflected uterus Rosenthal has reported a case of a woman, 23 years old, who suffered for three weeks from paresis of the legs, coming on after pains and cramps in the abdomen A needle was found deeply imbedded in the vagina, and the paresis rapidly disappeared after its removal

M Molard has recently published[3] a case of amaurosis, in which it is fair to assume that a tape worm was an, if not the, etiological factor The patient, a man, was seized with sunstroke, and subsequently exhibited symptoms of cerebral congestion, accompanied by amaurosis This condition disappeared for a time and then returned The muscles of the neck were stiff, pharyngeal spasm occurred, he became insensible, delirious, and presented amblyopia, with dilated pupils It was then ascertained that the patient was *subject to frequent cerebral attacks of a similar character*, and that each attack coincided with the expulsion of fragments of tænia The bark of pomegranate root was administered, the worm was expelled, the patient's condition improved, and he was finally cured

Dr W B Hadden[4] records some very interesting cases of aphasia and paralysis occurring in chorea. He calls "attention to the apparent resemblance which exists between the speechlessness of chorea and the motor paralysis Both are transitory conditions, probably dependent on inhibition of motor centres and not necessarily due to exhaustion by antecedent spasm '

We may admit that it is against all analogy with what is usually seen that vascular constriction to the extent of causing paraplegia (as has been held) will be persistent But there are some cases which can scarcely be explained as being due, not to reflex irritation, but to a definite abnormal condition of the peripheral nerves, that affected the cord by lines of anatomical transmission As Fox[5] very properly remarks, it is the very essence of the pathology of the sympathetic system that the irritation in one organ can be reflected through a sympathetic ganglion as a centre of a reflex arc "but that such an irritation can reflect through a ganglion a persistent constrictive effect on a vessel seems to militate against the ordinary phenomena of physiology and disease. And yet it is only fair to place upon record any facts that, exceptional as they may be, tell in any way against this commonly received dictum The following instance is a case in point

"A very sensible and active shopwoman, 36 years of age, gave the following account of herself She believed that she had been born blind of the right eye At any rate she remembered, when she was a very little girl, being taken to see an oculist in London, who said she would never see with that eye She could not distinguish light with it In January, 1882, she had a canine tooth on the right side of the mouth extracted She immediately became conscious of light, and in a few days entirely gained sight in this eye The optic disk and retina were perfectly normal, yet for thirty six years she was quite blind, apparently from some reflex influence connected with the alveolus of that tooth With such an instance, it may not be well to speak of the impossibility of reflex irritation or reflex paralysis being persistent for long periods Nor is it well to speak, as does Dr Nixon, of the physiological impossibility of a true reflex paralysis

Some authors hold that in order to establish a causative relation between different local lesions and paralysis, it is necessary to show that the former precede the occurrence of the latter in a large number of cases, and that when we consider that the various local diseases which are supposed to have causative connection are not associated with paralysis in the vast majority of cases, such a connection, when the association exists, is conjectural But I do not see that the causative relation is so conjectural, even if the number of cases be small comparatively The number of people, for example, in whom quinine will produce a rash is very small, and the number of people who always have urticaria after eating shell-fish is also very small Yet the authors, some at least, who hold that the causative relation of local irritations to paralysis is conjectural distinctly avow that urticaria may be caused by eating shell fish It seems rather inconsistent to hold that the one cannot set up a reflex paralysis while the other may cause a reflex cutaneous affection

In reflex paraplegia, according to Ross, the paralysis is never complete, and Charcot says that the reflex activity of the cord is never increased There is absence of pain in the loins, of girdle pains, dysæsthesiæ, anæsthesia and of contractures (?), of paralysis of the bladder, and of bed-sores and other trophic disturbances (Ross)

Fagge thought that "the only way in which one can exclude the possibility that the relation between the primary disease and the paralysis is purely accidental, is to show that the cases in question are too numerous to admit of such an explanation But can this be shown? I must for my part confess that I have never yet had under my care a patient who appeared to me to be suffering from reflex paraplegia"[1] He thinks it scarcely possible to exclude hysteria as a cause of the loss of power in those cases in which women rapidly recover from paralysis after reduction of a flexed uterus But is there any more reason why a displaced uterus should not cause reflex symptoms than that they should be caused by intestinal worms, by dental irritation, or by stricture of the urethra? Graves recorded the case of a man who was admitted to the Richmond Hospital in 1835 with partial paraplegia of two weeks' standing, and a tight stricture which had existed for some months " "He had recently been exposed to cold and wet, and this might have been regarded as the cause of the paralysis But in a very few days after the first introduction of a catheter a remarkable improvement took place in his legs and in his back, where he had much pain In fact, the change was almost sudden, and within a month the power of the lower limbs was almost restored It would seem that we may fairly regard this as a case of reflex paraplegia" But it seems that there is much more reason for regarding this as a case of recovery from slight myelitis, in view of the length of time required for recovery, than many of the cases of true reflex paraplegia which have been regarded as doubtless due to hysteria or myelitis

---

[3] Receuil d'Ophthalmologie quoted in the British Medical Journal Nov 21 1885

[4] St Thomas s Hospital Reports n s Vol XIV

[5] E Long Fox Influence of the Sympathetic on Disease London 1885

Again, it is not at all unreasonable to suppose that many cases commence as reflex cases, but that long persistence of the irritation may set up a myelitis And if we hold that the cases of supposed reflex irritation are really due to myelitis, we are reduced to the pathological absurdity of maintaining that a myelitis may be entirely cured within twenty four hours, or else that all the cases of quick recovery on the removal of an irritation are mere coincidences of nervous affection and the presence of an irritant[3] In reply to those who say that it must be shown that the cases in question are too numerous to admit of any other explanation than that of coincidence, it may be said that they are too numerous It is not at all necessary to confine the evidence to cases of paraplegia. If the presence of an intestinal irritation can cause general convulsions, chorea, incontinence of urine, epilepsy and aphasia, or decay of a tooth headache, a nasal polypus epilepsy,[4] nasal irritation cough, etc, it is entirely admissable to hold that paralysis may be solely due to irritation conveyed reflexly Even admitting that many of the cases occurring in women may be fairly attributed to hysteria, we may practically exclude hysteria in the cases of young children who have presented these symptoms and recovered almost immediately after removal of an irritation an irritation which, had it been proved and produced in slighter affection, would certainly be held to be the direct cause of the affection

Eichhorst[1] says The name reflex paralysis is based on the idea that affections of the peripheral organs can so act on the cord that spinal paralyses are produced therefrom They almost always appear as paraplegias Reflex paralyses most frequently appear in connection with diseases of the uro genital and intestinal apparatus The possibility of the occurrence of reflex paralysis in the proper sense must certainly be admitted for those cases in which a paralysis disappears almost immediately after the cause is removed, as it can scarcely be due to anatomical changes in the nervous system, still, in our present experience these changes are the exception

Lewisson's theory, which is probably correct in true reflex paralysis, is that the paralysis is due to an arrest of the functions of the motor nerve centres, in consequence of excessive irritation of the sensory fibres" We need not go so far as Jaccoud, and say that reflex paralysis paraplegia is due to an "exhaustion" of that portion of the cord upon which fall the stimuli conveyed upward by the sensitive nerves belonging to an irritated part, a theory which is unsupported[3] It is only necessary to know that the sympathetic ganglia can act as independent centres for reflex arcs[4] This takes place as each blood-wave in its passage along the arterial system, forms the stimulus to the eisodic conductors to one another of the minute sympathetic ganglia found along the course of all the blood vessels, their function being the reception of these stimuli from the fibrils excited by the blood wave, and reflecting the order for contraction down the exodic fibres to the vessels again[5] Sorgenfrey has raised the question as to whether Landry's paralysis[6] may not be due to vaso motor disturbances (in a report of a case cured by ergot)

These considerations naturally suggest the idea of Eichhorst,[7] that the aphasia of chorea, catalepsy, intestinal irritation, etc, is due to ephemeral circulatory trouble, by which he must mean vaso motor trouble, and necessarily a reflex vaso motor trouble Martin Bernhardt[8] recognizes reflex action from the digestive tract as an etiological factor in aphasia (reflex aphasia) We know that contraction is the function of the vaso motor nerves most frequently called into exercise Now in paraplegia by compression white lines are more easily produced by irritation of the skin than red lines (the so called meningeal lines), and it is to be noticed that in both the cases reported by the writer white lines were produced when the finger was drawn across the legs

The application of the doctrine of "inhibition" to paraplegia was made by Lewisson in 1869 In a series of experiments on rabbits he succeeded in paralyzing the lower limbs by squeezing the kidney, the uterus, or a loop of intestine The loss of power continued while the pressure lasted, or a little longer, and disappeared abruptly In *Guy's Hospital Reports*, 1868, Mr Salter gives two cases in which caries of wisdom teeth not only caused severe pain in the arm, but partial paralysis of the muscles In one case all the symptoms passed off as soon as the tooth was drawn, and in the other a like result followed within a few hours after drawing the tooth Fagge refers to these cases, and admits that they, and some cases of paraplegia occurring coincidentally with intestinal worms, are "in perfect accord with Lewisson's experimental results, since they subsided as soon as the source of irritation was removed" Just how many cases of an almost exact similar nature, with abrupt termination on removal of a coincident irritation, have been reported can only be learned by a thorough examination of medical literature The cases reported in this paper have been found in a very short time and with a very limited literature at hand But I think that a sufficient number have been referred to to permit the idea that the nervous affections and the irritants are not always mere coincidences, and that even when the affections occur in women it will not do to say always that "it is scarcely possible to exclude hysteria as a cause of the loss of power"

[2] Fagge l c, p 407

[3] C B Radcliffe (Reynolds's System of Medicine Vol II London Ed, 1878) says that reflex paraplegia differs diametrically from paraplegia produced by myelitis 'In paraplegia from myelitis the paralysis is associated with tingling numbness or anæsthesia not so in reflex paraplegia In paraplegia from myelitis paralysis of the bladder and lower bowel is a marked phenomena not so in reflex paraplegia In paraplegia from myelitis the paralyzed muscles are usually atrophied and degenerated not so in reflex paraplegia In myelitic paraplegia cure or even improvement, is the exception in reflex paraplegia it is the rule But the diagnosis between reflex paraplegia from congestion of the cord is extremely difficult I would not say that the paraplegias differ diametrically but simply that paraplegia from myelitis is a more complete paralysis

[4] Fincke Deutsche med Wochenschrift No 4 1886 quoted in Jahrbuch d Pract Med Hft 1 1886

[1] Specielle Pathologie und Therapie Bd III

The inhibitory' theory It seems however that he should have inserted the word *certain* before "motor nerve centres'

[3] Unsupported pathologically though by no means untenable and certainly not unintelligible as Fagge seemed to think

[4] While we may admit that cases of reflex paraplegia are due *to an affection* of the central nerve structure of the lumbar region cord it is not at all necessary to hold that the cord is damaged

[5] Fox l c

[6] Acute ascending paralysis

[7] L c Bd III

[8] Virchow's Archiv Bd 102 S 26 quoted in Jahrbuch d Pract. Medicin 1886 p 312

Bramwell,[1] in discussing the functional paralyses occasionally resulting from peripheral irritation acting reflexly, says that the cases in which there is an organic lesion of the cord cannot correctly be termed *reflex*, if we understand by that term *a functional paralysis due to peripheral irritation acting reflexly* "True reflex paralysis is undoubtedly rare, but that it does occasionally occur in man seems beyond dispute, and that it can be induced in the lower animals seems proved by the remarkable chloroform experiments which Brown Sequard has lately published The diagnosis of reflex paralysis is always hazardous, and should only be made when

1stly There is no evidence of organic disease

2dly There is a manifest source of peripheral irritation

3dly and *chiefly* The removal of that irritation is followed by disappearance of the paralysis

Temporary paralysis due to vaso motor changes in the cord are sometimes met with and are clearly functional in character"

ARSENITE OF BROMINE IN DIABETES MELLITUS

BY N S DAVIS, JR, A M, M D,

ADJUNCT PROFESSOR OF PRINCIPLES AND PRACTICE OF MEDICINE IN THE CHICAGO MEDICAL COLLEGE ATTENDING PHYSICIAN TO THE MERCY HOSPITAL

In July, 1884, an article appeared in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, written by Austin Flint, Jr, on "Diabetes Mellitus" In this article he recommended for medicinal treatment the liq brom arsenitis, first suggested by Clemens

During the last year I have had opportunity to try this drug in a considerable number of cases They have so uniformly progressed favorably that I have thought it worth while recording them It is difficult, however, to estimate justly the action of any drug in this disease, for we know that a proper modification of the diet will alone produce the most marked curative effects, and probably no one ventures to treat a case without simultaneously regulating the patient's diet

The first case in which I used the arsenite of bromine was that of a lady past middle life, living in a neighboring city She had for several months been losing strength and flesh She complained of a perverted appetite for liquids, and noticed that the urine was passed with frequency and in unusual quantities The symptoms that are most noticed by the patient were an unnatural weariness on slight exertion, and a very considerable loss of flesh, amounting to twenty pounds or so in six or eight weeks In this case, there was frequently present a peculiar stinging pain in the tongue, and a twitching of that organ

When the urine was examined, it was found to be heavily laden with sugar A strict diabetic diet was prescribed, together with the arsenite of bromine in three drop doses three times daily, also granules of digitaline, each of one sixtieth of a grain The latter was used to steady and strengthen the heart's action, which was unusually weak and somewhat irregular

At the end of the first week, a trace only of sugar was found in the urine and all the symptoms were mitigated The dose of the arsenite of bromine was increased to five drops At the end of the second week, or a little sooner, all trace of sugar disappeared from the urine, and there was a steady and marked general improvement This improvement was steadily maintained, and in two months from the time the patient came under treatment, she was feeling quite herself again Although frequently tested, the urine never showed signs of sugar after its first appearance The patient was as faithful for four or five weeks to the prescribed diet as one can be, and returned to an ordinary diet very gradually She has been under observation for nearly a year now and has shown no signs of a relapse

The second case was also in a woman, a little past middle life, but in the middle class of society When first seen she complained of excessive weakness, which had gradually but, somewhat rapidly stolen upon her, and an excessive and seemingly unquenchable thirst She had lost flesh only moderately The appetite for food was scarcely up to the average The urine was more abundant than normal, and was clear and limpid She was so weak, or as she expressed it, "so tottering upon her feet," that she could scarcely walk across the room The weather was sultry, but her skin was dry

She, also, was placed upon the arsenite of bromine in five drop doses three times daily, and her diet prescribed In the use of a restricted diet she was not at all persevering I think, therefore, that in this case little of the improvement which followed treatment can be ascribed to the food eaten or rather uneaten

---

[1] Brain Vol IV p 41

In a week from the first visit she had so far improved that she could easily get about the house, and the sugar had disappeared almost entirely from the urine The thirst had disappeared, and in every way she was improved I did not get a sample of the urine to test until ten days had passed, and in this no sugar was found Improvement continued steadily After this date I ceased to hear from her directly From other members of her family, who consulted me in regard to themselves, I learned from time to time during several months that she was feeling quite well

The third case that came under my observation in this period is not worth recording, as after making a diagnosis and prescribing as in the former cases, it passed into other hands It was a gentleman already under treatment who came to me for additional counsel

The fourth case was that of a lady in the best station of life, about fifty years of age She had been under my father's care for four or five years, and my own, at times, for two years In her case the diabetes usually came readily under control, but in from six to nine months there was apt to occur a relapse These relapses were marked by loss of flesh, but much more marked loss of strength and energy She had during all those years adhered to a modified diabetic diet, being allowed a very little sugar in her coffee in the morning, and a very moderate amount of wheat bread The relapses, or return of diabetic trouble, could nearly always be traced to over-exertion and a little laxity in the diet If she attended two or three lunches or receptions in quick succession, and was tempted to take preserved fruit or cake, a new outbreak of the disease was very apt to follow

At the time of which I now write she was suffering from an attack thus provoked In addition to the usual loss of strength and energy and the presence of sugar in the urine which ordinarily marked her attacks, she suffered severely from pruritus vulvæ She had begun to exercise rigid care about her diet of her own accord, two or three days before consulting me There was, however, abundance of sugar in the urine As previously she had appeared to recover quickly under the use of small doses of calomel maintained for a few days, and a pill of extract of ergot of three grains, three times daily She was first placed upon the ergot, and, with the hope of getting the effect of the mercury, and still more marked effect upon the pruritus through arsenic, she was also given six drop doses of Donovan's solution three times daily As an external application, carbolized cosmolin was used She returned in two or three days, complaining of heaviness of the eye-lids and puffing of them There was slight but evident œdema of the lids The Donovan's solution was discontinued, and she was given a mixture of glycerine and citric acid, in the proportion of about eight to one, which she had previously used with benefit A week later she was not feeling much better, although the urine contained less sugar The pruritus still persisted

At this time the use of arsenite of bromine was begun In a few days all the symptoms were mitigated, and in two weeks she was feeling as well as usual The sugar entirely disappeared from the urine soon after the arsenite of bromine was employed

The next case was that of a man living in the central part of the State, who was unusually large and ponderous He came to the office complaining of lack of energy, weariness on slight exertion, and pain, particularly in one ankle, which some months before had been sprained His appetite was unusually good, but there was no great thirst He passed urine frequently, and very large quantities, filling an ordinary *pôt de chambre* full between ten at night and seven in the morning The urine was of a light amber color, clear, and contained a large quantity of sugar He had lost flesh, and was steadily losing, although still unusually heavy The loss of energy and strength was, however, most marked

His diet was carefully prescribed, and the arsenite of bromine in five drop doses, three times daily, was ordered A week later, no sugar could be found in the urine, and he said he thought he felt a little better generally The quantity of urine secreted was much less At the end of the second week he was feeling very greatly improved, his strength and natural energy had very considerably returned, and as he expressed it, he was getting back some of his old spring and elasticity of gait The pain in the ankle about which he first complained was nearly gone I had thought that that was only in part due to the sprain which his ankle had suffered, but was in part rheumatic, and accordingly at the end of the first week I gave him a pill of salacylic acid of two and a half grains, four times daily, in addition to his other medicine Steady improvement has taken place in this case, and no sugar has been detected in his urine after the first week of treatment

The next case was also that of a man residing some fifty miles from Chicago He was in the middle period of life For some months he had been losing flesh, having lost as much as twenty pounds in all He complains much of the quickness with which he becomes wearied when walking, especially in the legs below the knees His countenance presents a worn appearance, the color of the face is sallow, he urinates more frequently than natural, and copiously The first sample of urine shown me was slightly redder than natural At the bottom of the bottle there was a slight cloud of mucus, and over the sides and bottom numerous fine, beautiful reddish crystals of uric acid No albumen was found in the urine, but after filtering off the sediment the characteristic reaction of sugar was obtained

The treatment prescribed consisted in directions as regards diet, and the use of arsenite of bromine as in the last case Ten days later the urine appeared clear and contained no sugar He is still under observation, and although there is a little improvement in his feelings generally, only three weeks have passed since he was placed under treatment, and we cannot yet judge of the result

In these cases, I have continued to use the arsenite of bromine for some weeks after sugar had disappeared from the urine, and until the ability of the patient to bear a more varied diet had been tested In these cases, improvement, and decided improvement came promptly upon the use of the remedy

In regard to the diet, sugar and food containing it, and vegetables rich in starch were forbidden Bread was allowed only in the most moderate quantities Patients are always desirous of explicit directions in regard to diet, and I have found it convenient and useful to give them a written or pantagraphic copy of the following

ARTICLES OF FOOD FORBIDDEN

Bread, cake, pastry of all kinds, and food prepared with flour, cracked wheat, oatmeal, rice

Potatoes, turnips, beets, beans, corn, carrots

Prunes, grapes, figs, bananas, pears, apples, preserved fruits

Liquors of all kinds, whether distilled or fermented

ARTICLES OF FOOD PERMITTED

Soups, except those rich in vegetables, meat of all kinds, fish, eggs, oysters

Radishes, cucumbers, cresses, celery, lettuce, spinach, cauliflower, cabbage, tomatoes, oyster plant, onions, string beans, parseley, mushrooms, salads, pickles, olives, oil

Lemons, gooseberries, currants, sparingly of raspberries, strawberries, oranges

Milk, tea and coffee without sugar, but with glycerine in its place if desired

More or less variation can be allowed from this in mild cases, and in severe cases more rigor may be required, although it is difficult to hold a patient to a diet more rigid than the above

It is well known that in many cases of diabetes severe mental strain, sorrow or shock, seems to be the exciting cause of the disease I have observed this so often that I carefully inquire in all cases for it I am sure that in a large proportion of the cases that have come under my observation some such mental strain was present during the forming period of the disease In the first of the cases here mentioned business difficulties, added to still more perplexing and worrying family cares, were present during the time when flesh and strength were most declining In the second and third cases no such causes could be found In the last two business trouble was coupled with family sorrow In the fifth case the disease broke out just after the man's entire property had been lost in stock speculation If any mental influence played a part in producing the disease in the fourth case it was sorrow

In a very recent number of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION Dr Austin Flint, Jr, has published a list of cases of diabetes in which the disease had occurred in near blood-relations The fourth case that I have described might be added to this list, as her mother also suffered from diabetes, and finally died from the effects of carbuncles which complicated it

MEDICAL PROGRESS

ATROPINE IN POISONING BY MORPHINE —In the *Vratch*, No 44, 1885, p 733, DR J L JAVORSKY, of Tashkent, records the case of a strongly built and generally healthy midwife, aged 33, who attempted to destroy herself by taking at 1 A M about 30 grains of acetate of morphine and half an ounce of tincture of opium, *Pharm Rossicæ* (1 10) No nausea or vomiting occurred She fell asleep and awoke about 8 A M, looking very ill When first seen by the author (at 9 A M,) she lay speechless in a comatose state, with irregular slow superficial breathing, extreme myosis, her jaws being firmly pressed together A hypodermic injection of a fourth of a grain of apomorphine produced vomiting in fifteen minutes, after which the author succeeded in introducing into the patient's stomach about six ounces of strong coffee, with a large quantity of tannin The patient's state however, steadily grew worse At 11 P M the author began to inject one sixth of a grain of sulphate of atrophine every fifteen or thirty minutes Exactly one grain of the alkaloid was used up to 3 P M causing only a moderate mydriasis, but no improvement in the state of the patient, who lay now pulseless, breathing only five times a minute In spite of the apparent hopelessness of the case, the author went on injecting atropine, alternating it now with injections of tincture of musk And his energetic efforts were fully rewarded, about 9 P M the pulse became full, 90 a minute, and the breathing regular, 12 a minute At 11 P M the patient became conscious and asked for drink Having passed a quiet night, she rose on the next morning free from any danger The whole amount of atropine injected from 11 A M till 9 P M was 2 03 grains, that of tincture of musk, about 2 drachms Dr Javorsky thinks that his case strongly supports the theory of an antagonism between atropine and morphine (as upheld by Binz, Benzold, Henbach, etc, against Onsum, Camus, Bois, Knapstein, Dokhman, etc) [Dr R Neale's *Medical Digest*, sect 376 5, contains a series of cases of morphine-poisoning cured by atropine In the *Voenno Meditz Jurnal*, August, 1877, Dr Dobrokhotoff describes recovery after poisoning by 10 grains of morphine dissolved in 5 ounces of bitter almond-water, the patient, a weak woman, aged 24, was treated by atropine, administered both hypodermically and internally (altogether 2–5 grains), tincture of belladonna 30-drop doses, powder of musk in 1 gramme doses, etc In the *Vratch Vedomosti*, No 27, 1883, p 4162, Dr Rodzewicz publishes a recovery after 8 grains of hydrochlorate of morphine, the treatment consisting in enemata of coffee infusion, friction, electricity, wine, etc —*Rep*] —*London Medical Record*, March 15, 1886

SEPTIC AORTITIS —At the meeting of the Pathological Society of London, on April 6, 1886, DR F CHARLEWOOD TURNER showed three specimens of septic aortitis, and a microscopic section from a fourth case The first specimen showed the aorta extensively ulcerated, with undermining of the endarterium This was obtained from a female, aged 62, who had aortic incompetence, with hypertrophy and dilatation of the left ventricle, and granular kidney Microscopic section from one of the ulcers showed masses of micrococci in the deepest layer of the endarterium, at the base of the ulcer. The second specimen showed massive fibrinous coagula in the arch of the aorta; this was from a case of burn, fatal on the twenty fifth day, from suppuration and pyrexia. The third specimen was from a man who died of secondary hæmorrhage, from a wound of the left internal mammary artery. A fibrinous mass was found adherent to the aorta near the valves, with smaller fibrinous deposit on atheromatous elevations. A fourth case was mentioned, in which a similar lesion was found in a patient who died on the second day after primary amputation of the thigh. A microscopic section showed masses of leucocytes about the vasa vasis in the outer and middle coats, great swelling of the intima with corpuscular infiltration and exudation in the most superficial layer, and cloudy granular fibrin on the surface. The arterial lesion in all the cases was referred to the combined effect of structural disease and septic contamination of the blood, weakening the resistance of the tissues, and giving a grave character to the lesion. The difference in anatomical character between the lesion in the first case and in the other was attributed to the predominance of the former factor in the one case, and of the latter factor in the other. The vascular lesion in this specimen was regarded as indicating the starting of similar lesions of the pulmonary artery or venous trunks, and of thrombotic lesions of smaller vessels, associated with severe endocarditis.—*British Medical Journal, April 10, 1886.*

THE ASSIMILATION OF IRON.—Much difference of opinion has existed as to the method of action of ferruginous tonics. That their use is of advantage is a matter of daily observation, but many difficulties arise when we attempt to explain their mode of assimilation, for, apart from the fact that nearly if not quite all the iron so ingested is recoverable in the feces, we are met with the equally perplexing fact that iron salts when introduced into the blood stream cause toxic symptoms analogous to those induced by arsenic.

It has long been recognized that the iron entering into our structure is not normally derived from any inorganic salt, but from one or more complex iron-containing compounds existing in our food, and to be found typically, of course, in milk. BUNGE, in the *Zeitschrift fur physiologische Chemie* for 1885, records the extraction, from milk and from egg yolk, of this iron-containing organic compound, to which he gives the name of hæmatogen.

Hæmatogen markedly resembles hæmoglobin in molecular composition, though a still more close molecular resemblance may be traced between it and nuclein, if we ignore the absence of iron in the latter body. Bunge has extracted hæmatogen from the cereals and leguminosæ, and states very distinctly that our food "contains no inorganic iron combination, the iron present being in the form of complex organic compounds, which are built up by the vital activity of the plant, that in these forms the iron is absorbed and assimilated, and that from them the hæmoglobin originates."

Starting from these premises, Bunge's explanation of the value of inorganic iron salts in chlorosis is very interesting. The catarrhal state of the alimentary tract present in this condition favors a process of fermentation which induces the decomposition of hæmatogen. But when the inorganic iron salts are present, the sulphites evolved in decomposition attack such salts, with the result of sparing the hæmatogen. Confirmatory to this theory is the recent method of treatment of chlorosis, in which the disinfection of the digestive tract by the administration of small antiseptic doses of hydrochloric acid, after meals, has been found more efficient than the use of iron.—*Medical News*, April 17, 1886.

IN THE ACTIVE INGREDIENTS OF ERGOT.—In *The Practitioner*, of December, 1885, PROFESSOR RUDOLPH KOBERT, records a series of experiments with the active principles of ergot. Experiments with ergotinic acid, internally and hypodermically, on pregnant bitches, rabbits, cats, and sheep, show that it possessed no ecbolic power. Hence all aqueous extracts (as water dissolves only the ergotinic acid) are worthless. The *extractum secalis cornuti* of the German Pharmacopœia is an aqueous extract, and consequently is inert. Cornutine, is not to be confounded with the ergotinine of Tanret, as the latter is inert, produces uterine contractions both in animals that are pregnant and in those not. Sphacelinic acid is insoluble in water and must be given in an emulsion. In cats and dogs it provoked powerful labor-pains, followed rapidly by the birth of the fœtus. From this it is seen that in the ecbolic action caused by ergot both cornutine and sphacelinic acid take part. The latter acts directly on the uterus, while the former influences directly the centre for the uterine contractions, situated in the spinal cord. Professor Kobert had requested Gehe & Co., of Dresden to prepare an extract that contained both these active principles, which is called "extractum secalis cornuti cornutino sphacelicum Kobert." It does not keep well for longer than six months, but Professor Kobert emphasizes the statement that neither ergot itself, nor any of the numerous commercial European, and American, preparations that he has examined, retains their therapeutic powers for more than twelve months.—*New York Medical Journal*, April 17, 1886.

BENZOATE OF COCAINE.—SEÑOR ALFREDO BIGNON, in a paper read before the Lima Academy of Medicine, and published in *La Cronica Medica*, strongly recommends the employment of the benzoate of cocaine in preference to the hydrochlorate (the salt most commonly used), and to the salicylate and borate, with which he has also made experiments. He finds that the benzoate is extremely soluble, easily crystallizable, and retains the characteristic odor of coca itself. The antiseptic qualities of benzoic acid also are an additional advantage. Amongst other experiments, the anæsthetic effects of a 20 per cent solution of the benzoate were compared with those of a similar solution of the hydrochlorate in a case of epithelioma of the tongue, with the result that the effect of the former salt persisted for a much longer time than that of the latter.—*Lancet*, Feb. 20, 1886.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

The Editor of this Journal would be glad to receive any items of general interest in regard to local events or matters that it is desirable to call to the attention of the profession. Letters written for publication or containing items of information should be accompanied by the writer's full name and address, although not necessarily to be published. All communications in regard to editorial work should be addressed to the Editor.

Subscription Price, Including Postage.

Per Annum, in Advance	$5 00
Single Copies	10 cents

Subscriptions may begin at any time. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible remittances may be made at the risk of the publishers by forwarding in registered letters.

Address
Journal of the American Medical Association,
No. 65 Randolph Street,
Chicago, Illinois.

SATURDAY, MAY 8, 1886.

THE PRESIDENT'S ADDRESS.

The address of President Brodie will be read with more than usual interest by those members of the Association who believe, despite certain recent pessimistic uttterances to the contrary, that the American Medical Association has been and still is a great power for good in this country. In the matter of medical education it must be regarded as a significant fact that one of the earliest reports issued by a Committee of the Association was one "Upon a Uniform and Elevated Standard of the Requirements for the degree of Doctor of Medicine," and that in every college in which the recommendations of this report have been adopted the results have been satisfactory, and these colleges are now looked upon as the leading colleges in the country. The first steps taken in this country towards the requirement of preliminary education for the study of medicine were taken by the American Medical Association. The first step towards the separation of the powers teaching and licensing was taken by the Association, and there is now not a State in the Union in which the medical men are opposed to such separation. And it was a committee of the Association that first defined, on a basis of religion and morality, the duties and rights of the physician.

Certain members of the profession who, for financial reasons, have repudiated the defined duties of physicians, have sought to shield themselves by saying that gentlemen require no written rules for behavior, and attempt to fortify their position by saying that there is no Code in England. That there is a Code of Ethics in England, and that there is a positive need for one may be seen by referring to almost any current number of the *British Medical Journal*. That it is a necessity in this country is seen by the fact that every State Medical Society in this country, with one exception, has embodied the Code of Ethics of the American Medical Association, or an allegiance to its principles, in its constitution, and in the one exception it was repudiated by a minority meeting. The citizen may say that the gentleman has no need for a written criminal code, but the criminal code is made for the protection of good citizens as much as for the punishment of the bad. In everyday life it is the criminal class, the anarchist, communist and socialist, who complain of the stringency of the laws—not good citizens, who recognize and fulfil the duties of man to man.

The outspoken assertions of the enemies of the Association, some of whom are members of it, that the day of its usefulness has past, that it has never been a scientific body, and that it was never intended as such, is easily disproved by consulting the volumes of its Transactions, and, Dr. Brodie's few selections from the titles of the papers that have been published in those Transactions is very apropos just now. That such assertions have been made seems to show positive ignorance of medical literature on the part of some members of the profession. There is scarcely a subject in the whole range of medical literature that has not at some time been treated of in papers published in the Transactions of the Association. So far from the day of its usefulness being past we may say that the sun of its usefulness has by no means reached its noon. The medical profession of this country will not be content to sit and see a few men arrogate to themselves all the learning, all the prestige, and everything else which goes to make the complete professional man. Our country, our customs, and institutions are too democratic to allow a few men to style themselves 'representative.'"

The American Medical Association is entitled to the hearty support of every member of the profession who has the good of the profession at heart—every one, in short, who has entered upon the study and practice of medicine as a science, an art, a great and noble calling. As to those who have come in to make it a trade, the Association is better off without them.

REFLEX ACTION AND INHIBITION.

Reflex action, says Lauder Brunton, is the effect produced by an impression made upon a sensory nerve, transmitted by that nerve to a nerve centre, and reflected or thrown back along a motor nerve in much the same way as we may imagine a string running over a pulley and transmitted in a different direction by the other end to produce a certain effect. And if we suppose the further end of the string to be divided into several strands, each of which is attached to a different object, and which may be, separately or together, affected by a pull on the nearer end of the string, we will have a still more clear idea of reflex action, since the impression on the sensory nerve may bring about various results, depending on the strength of the impression and the efferent nerve channel along which it is sent back by the nerve centre. While it is to be remembered that a reflex movement is one caused by the stimulation of an afferent sensory nerve, it should also be remembered that voluntary activity is excluded in a purely reflex act. Again, we must judge of what is going on in an afferent nerve by the effect produced in a central nervous organ, in the way of exciting or modifying automatic or reflex action, or in affecting consciousness, and here we are met with the difficulty of clearly distinguishing between the events belonging solely to the afferent nerve, and those of the central organ. We know that an afferent impulse passing along an afferent nerve may give rise to reflex movements, or may modify existing reflex or automatic actions, or may produce both effects at the same time.

The mistake of supposing that a sensory nerve is one which bears a *sensation* to a central organ should not be made. An impression borne along a sensory nerve may affect the nutrition of a tissue, or it may produce voluntary or involuntary motion—affect a voluntary or involuntary muscle. Under the involuntary muscles which may be affected may be classed the muscular fibres of the blood vessels, and movements caused in them produce the vascular changes (which may be greatly influenced by impressions made upon sensory nerves) which play an important part in nutrition and secretion. We know that stimulation of a nerve—and we may even say one fibre of a nerve—may cause reflex action under certain circumstances, and under other conditions give rise only to a sensation, and thus it is that an afferent nerve is frequently spoken of as a sensory nerve. It has been thought proper by some to classify the centripetal or afferent nerves as sensory, nerves of special sense, and reflex or excito motor nerves. And the division is perfectly proper, if we remember that no sharp line of distinction can be drawn in the way of supposing that the stimulation of a nerve of one class always produces a given and the same effect.

These considerations lead us up to the subject of transference of impressions. We have spoken of the cord passed over the pulley; let us now imagine that the further side of this cord is divided into several strands, the nearer side being single, and as we may have several results from pulling on the nearer side by reason of the subdivisions at the further end, so we may have a subdivision of the nearer side of the cord, while the further end is single, it is apparent that we can produce the same result by traction on any one of the strands of the further side. Or we may illustrate this by taking the example of the telephone bell and the transmitter. The person at the other end of the wire turns the crank and our bell rings, we place the transmitter to the ear, and though the other person may continue to turn the crank our bell no longer rings, though we receive in the ear the peculiar ticking sensation indicating that the crank is being turned. Irritation of the uterine nerves by the presence of a fœtus may cause vomiting, or it may cause paralysis, as in a case reported by Jolly about a year ago, which, while he attributes it to an hysterical condition, was nevertheless caused by centripetal irritation. The sphincter of the neck of the bladder and the muscular walls of the organ may be reflexly excited to contraction, and there may be reflex incontinence or reflex retention. The presence of ascarides in the rectum may cause incontinence of urine, and so long as the ascarides remain we may vainly employ drugs for the relief of the incontinence. About ten years ago Mr. Teevan reported a most interesting case of incontinence which obstinately resisted all treatment until a fistula *in ano* was cured.

In the consideration of the subject of reflex action it is of importance to remember that the sympathetic ganglia may act as independent reflex centres. Pigmentation may be excited reflexly by cutaneous irritation in the frog when the brain and cord have been destroyed. The uterus possesses within itself all the elements for a reflex arc, as shown by the fact that it can act independently by expelling the fœtus after the death of the mother. A very important contribution to this subject was the paper read by Dr. Woakes at the London meeting of the International Congress, in which he shows both the independence of at least the vaso motor portion of the sympathetic, and of its many connections with the cerebro spinal system. He speaks of the inferior cervical ganglion as a correlating nerve centre, which must mean that it is a reflex centre. It is a well known fact that in prize fights a blow on the neck will cause unconsciousness more quickly and with less injury than any other blow about the head. The explanation is that the shock to the cervical nerves is propagated to the inferior cervical ganglion, thence reflected to the vertebral artery as a wave of vessel dilatation, this wave is first appreciated in its peripheral branches, producing an instantaneous large accession of blood to them This accession of blood in the internal auditory branch of the vertebral artery causes sudden tension of the intra labyrinthian fluid and unconsciousness is the result

We know that irritation of a sensory nerve will cause dilatation of the vessels in the part supplied by the nerve, and vascular contraction in other parts of the body As a rule this takes place without affecting the action of the heart, but the irritation may be so strong, or applied so directly to certain nerves, that the heart is affected, as is the case when the fifth nerve is strongly irritated The fumes of ammonia, strong acetic acid or chloroform when passed into the nostrils of a rabbit may suddenly and completely arrest the heart Not without reason does Dr Brunton attribute the numerous deaths which have occurred when teeth were being extracted under chloroform to an arrest of the heart by irritation of the dental branches of the fifth nerve In the waking condition the irritative effect on the heart from the extraction of a tooth is counteracted by the coincident contraction of the arterioles all over the body, but under chloroform the two reflexes are not equally influenced by the drug, and the reflex action upon the heart may remain after that upon the vessels has ceased, in this case the heart stops because the blood drains away from the arteries into the veins—or to use the simile of Ludwig, the animal bleeds to death into its own veins

Closely connected with this subject of reflex action is the phenomenon called inhibition The inhibitory nerves may be defined as those nerves which modify, inhibit, or suppress a motor or secretory act already in progress (Landois), we may then say that inhibition is the modification or suppression, through nervous influence, of a motor or secretory act already in progress Probably the most familiar example is the stoppage of the heart by a blow upon the belly, or a blow upon the intestine of the frog with the handle of the scalpel This is nothing more than the suppression of the discharge of reflex action But some of the examples given under reflex action are really examples of inhibition It is only necessary to remember that a reflex act may be inhibited or augmented or that an augmented reflex action may be inhibited We see augmented reflex action in some cases of hysteria inhibited by pressure on the ovaries—another example of suppression of the discharge of reflex action There need be no especial difficulty in comprehending the subjects of reflex action and inhibition, though some physiologists have created sad confusion by unintelligible explanations

DRUGGING IN THE DARK

Such is the practice complained of by a correspondent of a contemporary, who finds that many physicians administer medicines in what seems to be a reckless and unscientific manner,—"Strychnine, arsenic, digitalis and aconite, are favorite remedies in all sorts of diseases" Used in this connection, we may very well object to the word *remedies*, in other respects we must agree with the complainant, adding that in America quinine seems to hold a high place in the list of drugs that are prescribed when there is some little doubt as to the diagnosis "Pills and mixtures containing many poisonous drugs are commonly prescribed, even when the practitioner is quite in the dark as to what the cause of the disease may be With some, the rule is, when the cause is unknown, to mix a great many poisonous stuffs, in the hope that one of them may hit the enemy A wiser and safer course would be, when the diagnosis is uncertain, to give, in the name of remedy, something that cannot possibly injure the patient"

We are not at present prepared to say whether or not this is a growing evil, though it is to be hoped that it is not Without doubt it is due to a great extent to a habit of making "snap" diagnoses, or of making no diagnosis at all When a diagnosis cannot be arrived at immediately, a physician will often prescribe what he thinks will do no harm, with the hope that he can get at the truth of the matter when he next sees the patient This may be due to a suspicion that the patient thinks that he should be taking medicine, since the idea of taking medicine whenever possible is deeply rooted in the minds of the laity, as shown by the enormous amounts of patent medicines used In very many cases, however, a certain combination of drugs is given because some of the symptoms point to a particular affection, and this combination has been prescribed for that affection by a teacher or some eminent physician This is evinced by the books containing formulæ, compilations of favorite prescriptions, and ready reference books which seem to find such a ready sale It is often very difficult to convince a patient that he does not need medicine, but it is just as important that the physician should know when *not* to give medicine as when to give it Possibly more "drugging in the dark" is done in renal and cardiac affections than in any others, on account of an apparent obscurity connected with them Much of this is due to the fact that the urine is often improperly examined, and frequently not examined at all Much useless, or even harmful drugging would be done away with if physicians would thoroughly acquaint themselves with the principles and significance of arterial tension—increased and decreased After all the whole matter is resolved into the one principle Never give a dose of medicine without a clear and definite object in view, and a definite idea of the result to be attained

PROFESSOR WILLIAM S FORBES

Dr William S Forbes, for several years Demonstrator of Anatomy in the Jefferson Medical College of Philadelphia, was appointed, at the meeting of the Board of Trustees held on April 26, to the Chair of Anatomy, rendered vacant by the resignation of Professor William H Pancoast Apart from the eminent fitness of Dr Forbes for the position, his appointment is a just rebuke to those who, about three years ago, instigated against him a most malicious prosecution and persecution Since he was appointed as Demonstrator of Anatomy in the Jefferson College Dr Forbes has held a high rank as a teacher of anatomy, and added to this his personal popularity with students is very great He brings to his new position the triple qualification of a thorough anatomist, a good teacher, and a surgeon of most excellent judgment

SOCIETY PROCEEDINGS

AMERICAN SURGICAL ASSOCIATION

Seventh Annual Session, held in the Reading room of the Army Medical Museum, at Washington, April 28, 29 30 and May 1, 1886

Thursday, April 28—Morning Session

The meeting was called to order by the President, Moses Gunn, M D, of Chicago, who delivered his Annual Address, of which the following is an abstract

Custom, if not organic law, requires the President to open the proceedings by a more or less formal address My immediate predecessor, in his address a year since, suggested that either a résumé of the progress of surgery for the previous year, or some special scientific subject, should constitute the subject matter of the President's address I propose to comply with the spirit of this suggestion, and shall indulge in a few thoughts on

CERTAIN POINTS IN THE PHYSIOLOGY AND SURGERY OF MOTOR, SENSORY AND MOTO-SENSORY OR COMPOUND NERVES

Previous to the investigations of Magendi and Bell, no clearly defined effort had been made to differentiate the motor and sensory nerves It remained for these investigators to clearly establish the fact of the motor qualities of the anterior roots and the sensory qualities of the posterior roots With this also came the idea that this difference was intrinsic, due to peculiarities in the anatomical and physiological organization of the nerve fibres This appears to have been the idea generally entertained Is this a fact, or is the difference to be found in extrinsic conditions, viz, the anatomical organization at either end of the nerve, the nerve to trunk being simply a conductor of a form of force? Upon the facts of the case depends the possibility of satisfactory results in the section and physiological reunion of divided compound nerves and the grafting of one compound nerve upon another where there has been so great a loss of the trunk of the nerve as not to permit the approximation of the distal and proximal portions of that nerve Success in achieving satisfactory results by such operations or a uniform lack of success must afford a tolerably reliable answer to these interrogatories, much more reliable than experiments on some of the inferior animals Experiments on animals require severe scrutiny, or they may mislead Some of the experiments on animals were then referred to Philipeau and Vulpain divided in dogs the pneumogastric and sublingual nerves, and united the central end of the pneumogastric with the distal end of the sublingual They also divided the lingual branch of the fifth nerve and the sub lingual, uniting the central end of the lingual branch of the fifth nerve to the peripheral end of the sub lingual and tearing out the central end of the sub-lingual The result of these experiments was that after a time motion and sensation was restored Other similar experiments were cited

In April, 1880, Dr E P Davis made for the speaker the following experimental operation Under an anæsthetic, the axillary plexus was exposed The median was severed after its bifurcation and also the ulner and radial The outer head of the median was united to the ulnar The inner head of the median was united to the radial in the same way At the end of ten days, the dressing was removed and complete paralysis of motion and of sensation found In four weeks this began to disappear and later a perfect condition of motion and sensation was observed By this operation the distal portion of the median was left entirely without nervous supply, and yet there was no paralysis of muscles or integument supplied by this portion of the nerve Latter investigation showed that in the dog and certain other animals there is an anastamosis of fibres between different nerves, forming an indirect route for the conduction of nervous force

Nerve suture in man has become a recognized operation both as a secondary and primary procedure It must be concluded from experiments that motor, sensory and trophic powers depend not on the nerve itself, nor on a difference of nerve force, but on the organism at the end of the nerve itself Professor Stephani is reported to have succeeded four times in uniting the distal end of the median with the proximal end of the musculo spiral, and the distal end of the latter with the proximal end of the former Immediately following the operation was complete paralysis and atrophy, but in the course of six or eight months, there was not only restoration of muscular power, but harmony of action to an extent sufficient to permit the animal to run, but perfect extending power was not realized

The intergrafting of a section of a nerve of an inferior animal to replace extensive loss of nerve structure will probably be of too uncertain success to constitute a standard operation, but can the grafting of the distal end of a nerve in such a case upon the side of or into the trunk of an adjacent nerve secure to it a supply of nerve force? Experiments made by Kawa would indicate that such might be the case To establish this point experiments on dogs are valueless on account of the free anastamosis We must look for the solution of this question to the rare opportunities met with in the course of surgical practice to institute experimental operations on man A case has been reported by Després, where there was such extensive destruction of the median nerve as to preclude the possibility of approximating its ends He therefore engrafted the distal end of the median with the trunk of the ulnar Fifty-four days after the operation the functions of the parts supplied with the medial nerve were partially restored

On December 1, the speaker had occasion to resect the right ulnar nerve in the removal of a neuroma in a male patient aged thirty six years The distal portion of the divided nerve was grafted to the trunk of the median The sheath of the median was removed and the broadly chamfered end of the ulnar laid in contact with it and secured by three fine cat gut sutures Immediately after the operation there was complete paralysis of the parts supplied by the ulnar On the eighteenth day there was a slight return of sensation along the ulnar side of the ring finger and there seemed to be some contraction of the flexor carpi ulnaris Four months after operation, the patient could feel a slight touch on the ring finger, no sensation to touch in the little finger, but an increased warmth in it He can adduct the hand with considerable vigor, but as yet has no power over the terminal phalanges

The positive evidence which these two cases furnish at so early a date, warrants further effort in this direction, and corroborates the other evidence of the correctness of the postulate, that the function of a given nerve depends entirely upon the machinery at its ends and not upon any intrinsic quality

Favored by your kindness manifested one year ago, it is my duty to preside over your deliberations in this seventh session of the American Surgical Association We have come together to make and renew friendships and to impart to one another and to the surgical world the results of our experience, investigation and thought

As to the new friendships which shall ensue, let us hope that they will equal the old, and in the renewal of the old, let the grip be firmer and the heart still warmer, while in the spark which shall fly from the clash of thought let there be only the fire which purifies the subject, enhances esteem and cements friendship So shall our discussions be honorable to our selves and profitable to surgical science

A proposition to form a

CONGRESS OF AMERICAN PHYSICIANS AND SURGEONS

was discussed, and referred to a committee of three to report Thursday morning, the committee consisting of Drs J Ewing Mears, Wm T Briggs and Christopher Johnston

---

AFTERNOON SESSION

DR CHRISTOPHER JOHNSTON, of Baltimore, read a paper entitled

DIAGNOSTITIAL LAPARATOMY

This operation is as ancient as our race, but in early times was always practiced on the cadaver The first operation on the living subject was probably performed about the year 1600 The rapid advance of abdominal surgery now demands the attentive consideration of surgeons, and requires the expression of opinion as to the position of the line limiting interference in certain classes of cases The question in abdominal lesions arises, how shall the seat of the pathological change be reached? The answer is laparotomy, which makes the diagnosis positive in cases of doubt and is preliminary to other operations which may be required If the surgeon has no right to refuse to give aid to a fellow creature becoming asphyxiated from obstruction in the air passage, has he the option of refraining from surgical interference when the prima viæ are obstructed in their functions? The answer to this question hangs first upon the diagnosis, sometimes upon the record of the past, and not infrequently upon the wise boldness of the surgeon The propositions then are, first, that for abdominal surgical affections all possible operations ought to be attempted after the establishment of a precise diagnosis, and second, that when a just diagnosis cannot otherwise be reached it may and ought to be eked out by an exploratory incision The mortality of abdominal incision without complication is low A great consecutive mortality following a surgical procedure in no wise determines the want of value of the operation, while most cases recovering are to be considered a certain gain

The record with regard to diagnostitial laparotomy is very brief, for as a rule, when the surgeon approaches the case the diagnosis is already nearly positive The gravity of the operation is largely determined by the time at which it is performed The abdominal incision intentionally diagnostitial is fraught with so little comparative ill consequence that its high value or necessity may be fairly claimed as an established and proper aid to diagnosis Of all operations involving laparotomy, those involving the uterus and its appendages probably fill the largest space Next we have those involving the alimentary tract

Besides being a justifiable operation, abdominal incision becomes the bounden duty of the surgeon in a great variety of instances

When is exploratory laparotomy called for? It should be stated that to a certain extent every laparotomy is diagnostitial Without establishing unnecessary groups, two great classes in which exploratory laparotomy is demanded or permissible are to be recognized First, all sorts of cases in which the diagnosis cannot be made without its aid Second, all those cases in which, a diagnosis having been made, no definite line of operation can be marked out and no abandonment of active measures be entertained or justified Laparotomy holds the key in all cases of doubt as to what is the matter and what is to be done In intestinal cases, the early operations are those which save life the oftenest, but abandonment ought not necessarily to follow delay in invoking the surgeon's aid

Dr A Vanderveer, of Albany, said that there was no doubt that experience showed us that simple incised wounds of the abdomen without injury to the abdominal organs will usually heal without difficulty, even if left to themselves The mortality is very slight indeed Even when the injury is more serious recovery often follows The cases which give anxiety are those in which the bowel is injured and its contents escape into the abdominal cavity These die inevitably if nothing is done In these cases laparotomy should be performed This operation is often opposed by the friends of the patient and often by the attending physician, and much is to be done in the direction of teaching the profession and the public the importance of early operation in these cases Cases were cited of gunshot injuries of the intestine and of rupture of the intestine produced by external violence in which the operation might have saved life if it had been permitted by the friends of the patient The operation, as a rule, will not be allowed until the patient is in collapse, and it is then too late The masses must be educated to the necessity of laparotomy in the cases referred to This operation should be done more frequently in the future than in the past As regards the mode of operation, the incision in the median line is by far the best In some cases it would be impossible to reach the seat of disease by any other incision In the closing of the wound some recommend several lines of sutures uniting the different layers of tissue separately He does not believe that this is any advance on the old method of using sutures including all the layers of tissue Where there is great distension of the bowel in intussusception the discovery of the seat of trouble is greatly facilitated by a procedure which he had seen Tait adopt in such a case He opened the distended coil of intestine, permitted the gas to escape, and then closed the opening with sutures

Dr J Ewing Mears, of Philadelphia, in considering diagnostitial laparotomy, would arrange the subject in this manner First, external manipulation, second, internal examination where this is possible, third, aspiration, and finally laparotomy Laparotomy is much the most serious of all these methods In this discussion the subject of laparotomy as a means of treatment does not call for consideration The more experience he gained the greater was his conviction that the abdominal cavity should not be opened without due consideration Death is a severe penalty to pay for the perfection of the diagnosis The tendency at the present time seems to be in favor of opening the abdominal cavity rather than cultivating that essential skill by which the diagnosis may often be made without resorting to operation Tait's assertion that opening of the abdominal cavity is a matter of very little consequence has led many of the younger members of the profession to perform this operation without due consideration Having exhausted other methods of diagnosis, he thought that if the patient's life depends upon it, we should open the abdomen In intestinal obstruction the abdomen should be opened, many lives have been lost by want of courage on the part of the surgeon There is no question as to the duty of the surgeon in the case of gunshot wounds of the intestines

Dr Charles T Parkes, of Chicago, said that the paper insists upon the necessity of exhausting all other methods of diagnosis before resorting to laparotomy He thought that the size of the incision makes very little difference so far as the final recovery is concerned, but where the incision extends above the umbilicus, recovery is slower and attended with more inconvenience In the cases of laparotomy which he had seen where post mortem followed, there was no evidence that the abdominal incision had anything to do with the fatal issue In regard to the operation in cases of intestinal obstruction where the exhaustion is extreme, several years ago, he was called to see a case of nine days' standing The patient was in a state of extreme collapse, was put to sleep and the abdomen opened A small cyst was felt immediately beneath the fingers It ruptured and a quantity of offensive pus escaped into the abdominal cavity This patient recovered The abdominal opening should be made in the median line He thought that he had seen cases in which death has followed from the fact that the incision was not thus made, the surgeon being satisfied with enlarging the original wound In regard to closure of the wound, he considered the simple suture going through all the tissues the best Where there is much distension of the intestine the bowel should be opened He did not favor the use of the exploratory needle In two instances he had seen extravasation of fecal matter through such punctures

Dr McLane Tiffany, of Baltimore, referred to four cases of what he believed to be intestinal obstruction Two refused operation, and both of these died, two accepted, and one of these recovered The case that died was that of a woman aged 73 in whom the obstruction had lasted seven days The intestine was enormously distended, and in the examination ruptured with the escape of the gas After this it was extremely easy to find the seat of constriction He thought that shock would be less if the intestine is emptied He agreed with the speaker as to the great value of laparotomy as a diagnostitial operation It is not possible for any human being to recognize through the abdominal walls the manifold conditions of the organs present In regard to pistol wounds of the abdomen, it frequently happens that the intestines escape injury, and in these cases it is a question when the operation should be done The opening of the abdomen will probably not do much harm It is also very desirable that there should be in hospitals special rooms devoted exclusively to this class of operations

Dr J Ford Thompson, of Washington, reported two cases of laparotomy for the purpose of diagnosis A woman aged 35 years had the history of an abdominal tumor lasting for several years It presented the appearances of an ordinary ovarian tumor with the exception that it had two sinuses communicating externally After frequent examinations by various surgeons it was decided to make an exploratory operation One of the sinuses was traced back to the peritoneum without reaching any satisfactory explanation of the tumor The peritoneum was then opened and the finger introduced, but no tumor in the cavity could be felt Towards the abdominal wall a mass apparently imbedded in the tissues could be distinguished The wound was closed and the patient recovered from the operation The patient subsequently died, and the post mortem showed that the tumor was an enlarged spleen which had fallen down below the umbilicus and become attached to the abdominal wall

The second case was one of apparently freely movable tumor in the right hypochondriac region It proved to be a carcinoma involving the transverse colon There was also an attachment of the growth to the liver The abdomen was closed, the patient recovered from the operation, and is still living

Dr Johnston, in closing the discussion, said that there is a certain amount of hesitancy on the part of surgeons in regard to operating in cases of abdominal injury, on account of the people and on account of juries To overcome these objections it is necessary to educate the public to the true state of affairs In those cases where the bowel is opened laparotomy leads us to the seat of disease, and if anything can be done we are then able to do it He was happy to find his opinions supported by so many of the able minds of the profession

---

Thursday, April 29—Second Day

Morning Session

The President in the Chair

Dr Harold C Ernst, of Jamaica Plains, Mass, read a paper entitled

A CONSIDERATION OF THE BACTERIA OF SURGICAL DISEASES

After an extended description of the various bacteria met with in wounds, chronic abscesses, erysipelas and other surgical affections, and an account of numerous experiments on animals, with an exhibition of specimens in culture mediums and under the microscope, the author presented the following conclusions

1 The experiments conducted over so long a time with the successful inoculation at the end of that time, indicate very plainly the retention of pathogenic powers of these organisms indefinitely

2 Their permanence of form is also well established

3 In order to obtain either a modification of their pathognomonic forms or of their morphological properties—if this is possible at all, some different methods of investigation must be used than those which have hitherto been employed

4 The probabilities indicate that work in this direction is not likely to be successful

5 So far as the experiments go they tend to show that no form of the suppurative process in man is unattended by bacteria, and that the inoculation in the lower animals of pure cultures of these bacteria is followed by more or less acute and extensive suppuration

6 The above conclusion is supported by the evidence of all workers in this field of research

7 That a number of different clinical phenomena may be produced by the same organism, all of these phenomena, however, coming under the general head of the inflammatory and suppurative processes

8 That the difference in the results produced by the same micro organism in different individuals depends upon influences outside of the bacteria themselves

9 That these differences are the result of differences in the amount of the infectious material received into the system, and of the locality or lesions by which it gains access, and also by variations in the individual condition—the personal equation being a very large factor in making up the sum of any results in bacteriological work

Dr S W Gross, of Philadelphia, said that the observations made by Dr Ernst confirm those made by other observers, showing very conclusively that the suppurative processes are dependent upon vegetable organisms The most interesting part of the paper is that which relates to chronic suppuration The author has been, he thinks, the first to show that chronic suppuration is due to the same micrococci as the acute form

Dr J S Billings, of Washington, said that a mere verbal statement of the difficulties which attend these experiments gives no definite idea of the difficulties encountered in this work It is only by personal experience that they are learned The methods now employed are much more satisfactory than those in use some twenty years ago One of the difficulties in considering the probable relation between cause and effect in this work is that there seems to be no relation between the number of micrococci present and the effect produced A second difficulty is that we are by no means sure of the specific differences between these various forms of microscopical organisms As we cultivate bacteria in different media we find a change in their form It is perhaps possible that they may gradually change by alteration of the medium, of its chemical composition or of its temperature In connection with this subject, a study of the chemical conditions under which these organisms exist is necessary It is very desirable that the practical surgeon should have at his disposal the means of determining the presence of these organisms in any given case

Dr N Senn, of Milwaukee, said that he was in full accord with the conclusions of Dr Ernst, and did not intend to criticise what he had said He desired to say a few words in regard to the conditions which predispose to the action of germs introduced into the body The object of the surgeon should be, in the first place, to prevent the introduction of these germs, and in the second place, to secure innocuity to the infection by preventing the occurrence of predisposing causes The first predisposing condition is found in an unusual arrangement of the capillary circulation This is well illustrated in osteo-myelitis In this affection the germs are found in greatest abundance in those situations where the anatomical relations of the vessels predispose to engorgement and localization of the microbes, this is in the large vessels about the centres of ossification in the epiphyses of bones The second predisposing influence is traumatism The germs of osteo myelitis may be present in the body for a long time and produce no effects until the occurrence of traumatism, as a fracture, favors the localization of the microbes

Dr David Prince, of Jacksonville, Ill, exhibited a diagram and described a form of room where

A STERILIZED ATMOSPHERE

could be secured for the patient by means of air treated with corrosive sublimate and forced through a tube opening immediately above the seat of operation

The report of the committee appointed to consider the proposition for the organization of a

CONGRESS OF AMERICAN PHYSICIANS AND SURGEONS,

offered at the meeting of Wednesday by Dr C H Mastin, of Mobile, was called for The following is an outline of the main points of the proposition In view of the fact that there are a number of special medical organizations now in existence in the United States, each having for its aim the advancement of the special department of medicine for which it was organized, and since the members of the said special societies are the representatives of the profession in America, many of whom are at the same time members of several of these special societies, attendance at the meetings required separate trips from home, often with much loss of time Therefore it appears necessary that some arrangement should be made with the different societies as to an uniform place and time of meeting

The plan proposed is to unite the following named Associations into a Congress to be called "A Congress of American Physicians and Surgeons" The American Surgical Association, the American Ophthalmological Association, American Otological Association, American Neurological Association, American Laryngological Association, American Gynæcological Association, American Dermatological Association, American Climatological Association, and the American Clinical and Pathological Association The plan of organization embodies the following Each society is to elect its own officers, hold its own sessions apart from the others at the time and place of meeting, publish its own transactions and do all other acts which by virtue of its constitution and by-laws it has the inherent right to do, thus preserving its own autonomy

The Congress to be composed of these special societies when in convention and its meetings to be held in the City of Washington, the constitution and by-laws of the Congress to be formed by a committee of like number from each special society, the opening session of each annual meeting of the Congress to be devoted to such general business as may pertain to the interests of the Association as a whole The Congress being presided over by a President elected annually and who must deliver an opening address on the first day of the session The President to be chosen by a nominating committee of one from each special society, the Presidents of the special societies to be Ex-Officio Vice Presidents of the Congress Membership in the Congress is to be acquired only by virtue of fellowship in one or another of the special organizations The other officers to be elected as determined upon by the convention in session

We disclaim any intention of offering an obstacle or opposition to any other organization in America We propose simply a plan of uniting into one great body the already existing special societies, and we do so from an honest conviction that such a union will prove of inestimable benefit to them individually and collectively

The committee appointed to consider this proposition, reported that they viewed with great satisfaction the perfection of a plan through which the meeting of the above named societies at the same time in Washington may be accomplished, and recommended the adoption of a resolution that a committee of five be appointed to confer with committees from other special organizations to arrange details, and to report at the next annual meeting of the Association The resolution was adopted

The President stated that he would name the committee on Friday

Afternoon Session

Dr N Senn, of Milwaukee, read a paper entitled

THE SURGERY OF THE PANCREAS AS BASED UPON EXPERIMENTS AND CLINICAL RESEARCHES

The following conclusions were presented

1 Restoration of the continuity of the pancreatic duct does not take place after complete section of the pancreas

2 Complete extirpation of the pancreas is invariably followed by death, produced either by the traumatism, or gangrene of the duodenum

3 Partial excision of the pancreas for injury or disease is a feasible and justifiable surgical procedure

4 Complete obstruction of the pancreatic duct, uncomplicated by pathological conditions of the parenchyma of the organ, never results in the formation of a cyst

5 In simple obstruction of the pancreatic duct the pancreatic juice is removed by absorption

6 Gradual atrophy of the pancreas from nutritive or degenerative changes of the secreting structures is not incompatible with health

7 Physiological detachment of any portion of the pancreas is invariably followed by progressive degeneration of the glandular tissue

8 Extravasation of pancreatic juice into the peritoneal cavity does not produce peritonitis

9 Crushed or lacerated pancreatic tissue is removed by absorption, provided the site of operation remains aseptic

10 Complete division of the pancreas by elastic constriction is never followed by restoration of interrupted anatomical continuities

11 Limited detachment of the mesentery from the duodenum, as required in operations upon the pancreas, is not followed by gangrene of the bowel

12 In all operations upon the head of the pancreas the physiological attachment of the peripheral portion of the gland should be maintained by preserving the integrity of the main pancreatic duct

13 Partial excision of the splenic portion of the pancreas is indicated in cases of circumscribed abscess and malignant tumors, in all cases where the pathological product can be removed completely without danger of compromising pancreatic digestion or of inflicting additional injury upon important adjacent organs

14 Ligation of the pancreas at the point or points of section should precede extirpation as a prophylactic measure against troublesome hæmorrhage and the extravastion of pancreatic juice into the peritoneal cavity

15 The formation of external pancreatic fistula by abdominal section is indicated in the treatment of cysts, abscess, gangrene, and hæmorrhage of the pancreas due to local causes

16 Abdominal section and lumbar drainage is indicated in cases of abscess or gangrene of the pancreas, where it is found impossible to establish an anterior abdominal fistula

17 Through drainage is indicated in cases of abscess and gangrene of the pancreas with diffuse burrowing of pus in the retro peritoneal space

18 Removal of an impacted pancreatic calculus in the duodenal extremity of the duct of Wirsung by taxis or incision and extraction, should be practised in all cases where the common bile duct is compressed or obstructed by the calculus and death is threatened by cholæmia

19 In such cases, the principal source of danger, extravasation of bile into the peritoneal cavity should be avoided by preliminary aspiration of the dilated bile ducts, accurate closure of the visceral wound with fine silk sutures and absolute physiological rest of the organs of digestion, during the time required in the healing of the visceral wound

Dr Chas T Parks, of Chicago, read a paper supplemental to his paper of last year, reporting

TWO CASES OF CHOLECYSTOTOMY,

both of which ended fatally

Case 1, was that of a woman who had suffered with gall stones for six years The attacks of colic occurred as frequently as every week Operation was decided upon The gall bladder was found contracted and reached with difficulty Forty three calculi were removed

Case 2 was that of Mrs H , who for the past two years had suffered with attacks of pain lasting four or five days of each week There was jaundice and other symptoms of the obstruction of the flow of bile There was enlargement of the liver The operation showed that the gall bladder contained no calculi, but that the obstruction was caused by a body outside, which seemed to be an encysted calculus pressing on the duct The gall bladder could not be found The patient died within twenty-four hours, and the post mortem revealed the shrunken gall bladder with the induration, which contained a gall stone, pressing on the duct

Dr W H Carmalt, of New Haven, Con , related a case in the same line with these reported by Dr Parks The patient, a woman 37 years of age, had suffered for several years with indefinite dragging sensations in the right hypochondriac region This incapacitated her from performing her household duties In 1883, she stated that she had been operated on in Berlin for gloating kidney, and in evidence showed a large scar in the lumbar region She also stated that three weeks after operation, as a result of violent sneezing, the organ had become loosened She went to him for the purpose of having the kidney removed Examination showed the abdomen to be exceedingly pendulous The tumor was rounded, and could be readily grasped between the fingers, it was very movable It was decided, after keeping the woman under observation for some time, that the tumor should be removed An incision was made just external to the recuts muscle over the tumor When it was exposed, it was at once evident that it was not the kidney Further examination showed it to be a dilated gall bladder An aspirator was introduced, and four ounces of inspisated mucus drawn off The needle revealed the presence of a hard body Manipulation brought the gall stone up to the most accessible part of the bladder, and securing the gall bladder by two ligatures, he opened it and removed a stone as large as the end of his thumb Four other calculi were found After thorough cleansing the gall bladder was closed with a continuous cat gut suture The wound in the peritoneum was closed in the same way The muscles were united by interrupted silk sutures, and a continuous catgut suture was used for the incision in the skin The patient recovered without difficulty and is now able to attend to her duties, feeling better than for a long time

The report of

A CASE SIMULATING AND BELIEVED TO BE ABDOMINAL PREGNANCY AT FULL TERM—LAPAROTOMY, CÆSARIAN SECTION, AND REMOVAL OF A LIVING CHILD WEIGHING SEVEN POUNDS,

by Dr John S Coleman, of Augusta, Georgia

In the absence of the author, the paper was read by the Secretary

On February 27, 1886, the writer was requested to see B A , colored, primpara, twenty-four years old The attending physician believed her to be the subject of extra-uterine pregnancy She thought herself at the end of gestation, and for three days had suffered with pains which were quieted by the administration of laudanum The entire abdomen was greatly distended, particularly in the upper portion Vaginal examination showed procidentia, the os projecting three inches beyond the labia. The os was sufficiently patulous to permit the entrance of the index finger. Rectal examination gave negative results. Palpation and auscultation showed the position of the fœtus to be dorso anterior and obliquely transverse. Placental bouffle could not be heard. The abdomen was so large and the fœtal heart sounds so distinct that the writer also concluded that the case was one of extra uterine pregnancy. The patient was examined by a number of surgeons, who agreed in the diagnosis. The history and the symptoms indicated that the patient was at the full term of pregnancy, and it was decided that immediate surgical interference was imperative.

On March 31, the patient was operated upon. An incision six inches in length was made in the linea alba. The tumor exposed much resembled the pregnant uterus. The incision was extended above the umbilicus uterus, and it was positively determined that the case was one of uterine pregnancy. The uterus was drawn forward, and its anterior wall cut through. He had not conceived it possible for the uterine tissue to be prolonged from the epigastrium to three inches beyond the vaginal notch. A vigorous female child *weighing seven or eight pounds* was removed, the hemorrhage was not great, the placenta was removed without difficulty, the incision in the uterus was closed with deep and superficial catgut sutures, the peritoneum was closed with a continuous suture, and the abdominal wall with hair-lip pins and superficial sutures. Antiseptic precautions were adopted throughout the operation. Septicæmia developed—the patient living four days.

At the autopsy there was found no decided injection of the peritoneum, two moderate sized clots *were found on the peritoneum, the cavity contained* neary a quart of bloody serum. The uterus was one-half its former size, measuring from fundus to externum twelve inches, the cervix measured six inches, the wound was found gaping throughout.

The author then gave an extended view of the literature of the subject, and related similar cases by various operators.

To the paper was appended a letter from Mr. Lawson Tait, endorsing the performance of abdominal section in the above case, and asserting his strong objections to operations looking to the breaking up of the fœtus. He thought that a preferable operation in the present case would have been the Porro operation. This would probably have been successful both as regards the mother and the child.

FOREIGN CORRESPONDENCE

LETTER FROM LONDON

(FROM OUR OWN CORRESPONDENT.)

Another Lander Institute—The Peabody Industrial Buildings—Inquest on a Woman who died of Hydrophobia—The Wolf bitten Russians.

Another Lander Institute has been opened in London, in which fifty two machines are to be seen, the whole arrangements being under the charge of a medical man. The treatment is throughout perfectly painless. Gentleness is, as a rule, the last idea one associates with machines, weights, levers, and pulleys, but by Lander's mechanical methods it has been fully secured. Massage applied by human hands would at first sight appear to be superior, but experience is proving that the advantage rests with well regulated machines. The hand of the rubber becomes tired, and thus there is an almost constant variation of force, whereas the mechanical power continues its gentle movement without other increase or diminution than those intentionally produced by altering the adjustment of weights. The passive exercises are arranged on a similar principle to that of the massage, and are worked by an engine. The patients work the active ones themselves. Some of the machines look odd enough in their action upon the human frame. That called "vibrating" is intended for shaking the various parts of the body. Shaking of the back between the shoulder blades is to give a specific effect upon the action of the heart, making the contractions less frequent and more effective. Nervous palpitation is successfully treated in this way. The kneading machine is so arranged that the pressure of two rollers produces a kneading action. Cases of pain in the back are treated by means of a kind of couch, through the back of which two padded wheels roll along both sides of the spine. If necessary, one wheel can be raised higher than the other, and as with all the machines, the pressure can be adjusted to a nicety by the arrangement of the weights upon the lever. The friction machine for the hands and feet resembles a miniature tread mill. It is useful in cases of rheumatic affection in the extremities. There are machines for shampooing the legs and the arms, assisting defective circulation and developing the muscles. The saddle and side saddle are both passive, and are found efficient substitutes for horse exercise. Small india rubber hammers form of other machines the active portion for increasing the circulation inside and outside the scalp, or any portion of the body in which the muscles need stimulating. Sciatica has been cured, it is said, by applying these hammers to the region of the sciatic nerve. They can be raised or lowered so as to act upon any portion of the body.

From a recent report upon the cost and sanitary status of the Peabody Industrial Dwellings it appears that the average cost of the buildings erected by the trustees is £60 10s 2d per head, so that a family of four persons costs a capital sum of £242 to house, which is a much larger amount than is ordinarily expended by the speculating builder. As regards the acquisition of land, the trustees have been singularly fortunate, three sites having been sold to them by the Metropolitan Board of Works for a sum which leaves a clear loss of £235,808, or more than a quarter of a million to the ratepayers. Taking land and buildings together, a family of four persons costs £510 to house. A warning note is struck in the statistics of the mortality among the inhabitants of these dwellings. In the year 1884 the deaths per thousand of the total population of the Peabody buildings were 19.10, as compared with 20.34, which was the London rate, but in 1885 the death rate in the dwellings was actually *one* decimal point above the general rate of mortality in London, the figures being 19.60 in the Peabody buildings, and 16.59 for the whole of the metropolis. It would seem from these facts that, while the death rate of London has declined steadily since 1876, the death rate in these model dwellings has increased, since 1881, from 17.22 to 19.60 per thousand. It is considered that this increase is most probably due to the increased density of the population.

An inquest, which is likely to attract considerable attention in the medical world, was held in London on the body of an old woman who died of hydrophobia. Many cases of hydrophobia have been quoted in which, as far as any one knew, the deceased had never been bitten by a mad dog, but it was always possible that they might have been licked on some scratch or sore by a dog who was in an early stage of hydrophobia, or that they might have been slightly bitten, but had thought the matter of so little consequence that they did not mention it to anyone. In the present case the hypothesis is scarcely possible. The deceased had lodged for years in one house, and for months had not gone out. She had a dog to which she was very much attached. This dog is a very old one, being, it is said, seven or eight and twenty years of age. It, like its mistress, never went out of the house except into the back yard. It can never have escaped, for its mistress, who lodged up stairs, always carried it down, waited for it, and carried it up again. The dog has not been mad, and is still alive and in good health and there is no sign of a wound, scratch or sore on the corpse by which the virus could have been communicated. A more perfect test case could hardly be imagined. The two medical men who attended the deceased in her last illness declare that it was a distinct and undoubted case of hydrophobia, but in that case the assumption that hydrophobia can start *de novo* without the intervention of a mad dog, appears almost inevitable. So important did the coroner consider the case that he has adjourned it until next month, in order that it might be seen whether the dog continued in good health until that time.

Another of the wolf bitten Russians has died of hydrophobia whilst undergoing treatment on the Pasteur system to combat the development of the malady, and this unfortunate event, according to M. Rochefort—who entertains an unfavorable opinion of M. Pasteur and his theories—coupled with the other death, goes to prove that the inoculations made kill patients by communicating hydrophobia instead of preventing its appearance. As for the remainder of the Russian peasants who have left Paris for their own country, very likely, observes the *Intransigeant*, they will die when, or before, the get home, but the matter will be hushed up, or their deaths attributed to some other cause. When one reads criticisms of this kind one can well understand M. Pasteur's complaints about the attacks made on him in M. Rochefort's organ, and by certain members of the Paris municipality who share the antipathy that paper displays for him and his system. Whatever may be one's opinion concerning the value of the discovery he has made, it is quite certain that the distinguished savant has but one earnest desire, to benefit his species, and he ought not to be treated as a charlatan. As for his Russian patients, it is perhaps regretable, in the interest of science, that they were not kept, as he wished, another month or so in Paris under his personal inspection. During the present year forty-one cases of rabies have been reported in London, and one death from hydrophobia due to inoculation by dog bite.

G. O. M.

DOMESTIC CORRESPONDENCE

CARBOLIC ACID INJECTIONS IN HÆMORRHOIDS AND CARBUNCLE

To the Editor of The Journal.

Dear Sir:—Through the columns of The Journal permit me to place myself on record as the first to discover, and put in practice, the hypodermic administration of carbolic acid for the cure of hæmorrhoids, carbuncles, poisonous bites, small tumors, and foul and ill conditioned ulcers.

In 1875 I made my first injections in hæmorrhoids, carbuncles and snake bites, with most wonderful success. I continued the treatment for six years with uniform and unvarying success, and thus having satisfied myself of the value of this treatment, in 1881 I read a paper on the subject before the Texas State Medical Association, then convened in the city of Waco, Texas. This paper was entitled "The Hypodermic Administration of Carbolic Acid for the Cure and Removal of Foul and Ill-Conditioned Ulcers, both Internally and Externally Situated, Poisonous Bites, Hæmorrhoids, Carbuncles, and Tumors."

The paper met with strong opposition and severe criticism from many prominent members of the Association. Dr. A. M. Douglas, a leading man in the profession of this State, warmly espoused the paper and moved that it be published in the proceedings of the Association, which was done. I also had the paper published in the *Medical and Surgical Reporter*, of Philadelphia.

Dr. Wilkerson, of Galveston, and Dr. Woods, of Toledo, Ohio, claim to have been the first to discover and adopt this mode of treatment for the cure of carbuncles. While I do not doubt for a moment the claims these gentlemen have set up, and do not doubt they made the discovery as claimed, yet in justice to myself I must most respectfully claim priority of discovery and application of treatment.

Dr. Atlee, some two years since, in the *Medical and Surgical Reporter*, in animadverting on my paper read before the State Medical Association, claimed that the same treatment was discovered and resorted to during the Crimean War. If such was the fact, I have yet authentically to hear of it.

In conclusion, I beg leave to say to the medical profession that after eleven years of constant practice I find it still not only the best, but the only absolute and *painless cure* of these exceedingly painful affections. I further beg leave to say that carbolic acid, on account of its local anæsthetic effects, will, when applied to the cavity of an aching tooth, in a few minutes relieve pain. A bone felon can be lanced with almost no pain by first wetting it with carbolic acid. By wetting the gum around a tooth with the acid, the tooth can be extracted with almost no pain. I firmly believe at no very distant day carbolic acid will be *facile princeps* of conservative surgery. I fully intended to read a paper on this subject before the American Medical Association at its session in St. Louis, but circumstances over which I have no control have alone prevented me.

Very truly, N. B. Kennedy, M.D.

Hillsboro, Texas, April 27, 1886.

THE SURGEON-GENERAL OF THE ARMY.

To the Editor of the Journal.

Dear Sir:—Our British friends, who have, especially in recent months, manifested so kindly an interest in the medical profession of the United States, ought above all things to be accurate in their statements. We read on page 756 of the issue of the *British Medical Journal*, of April 17, 1886, in the announcement of the Fifty-fourth Annual Meeting of the British Medical Association, to be held at Brighton, August 10–13, 1886, that "An Address in Medicine will be delivered by Surgeon-General John S. Billings, M.D., Director-General United States Army Medical Department, Washington."

It is incomprehensible that a journal, which is the official organ of a great National Association, could have been misled as to the fact that the Surgeon-General of the United States Army is Brigadier-General Robert Murray, one of the most distinguished officers of a corps, which has more than one distinguished member, especially distinguished both as a physician and as a surgeon.

General Murray entered the army in 1846, was commissioned Assistant Surgeon-General on December 14, 1882, and has been Surgeon-General of the army since November 23, 1883. The official reports of the Surgeon-General's Office of the Army have all, since that time, been issued over his signature and by his act, and consequently a periodical of the character of the *British Medical Journal* ought not to have been ignorant of the personality of an officer of such prominence.

Dr. Billings was No. 44 on the roster of the Medical Corps, for January, 1886, and number 27 on the list of "Surgeons with the rank of Major," having only entered the service in 1862, and is on duty at the Medical Department as one of the six assistants (not Assistant Surgeon-General, this officer being Colonel Glover Perrin, another veteran practitioner, and surgeon of nearly forty years' service, not unknown to fame). The misstatements in this case only deserve correction on account of the injustice done in ignoring an officer of the professional reputation of Surgeon-General Murray. Accuracy.

NECROLOGY.

WILLIAM EDWARD SAUNDERS, M.D.

Died from acute Bright's disease at his home in Sherman, Texas, on January 14, 1885, Dr. W. E. Saunders. He was born in Tennessee, on April 5, 1828, was left an orphan at an early age, and adopted by his grandfather, who lived in Henry county, Virginia, where he was reared and educated in the common schools of that county, spending his early years upon a farm. When about the age of 22 years he left Virginia and went to Tuscaloosa, Alabama, and began the study of medicine with Dr. Gill, of that place. He attended lectures at the Nashville Medical College from 1851 to 1853, graduating in the latter year. Moving to Texas the same year he began the practice of his profession in Fannin county, where he remained but a short time, removing thence to Sherman, where he spent nearly all of the remainder of his life.

In 1861 he volunteered in the Confederate Army, and was appointed Assistant-Surgeon of the Eleventh Texas Regiment, in which he served until the fall of 1862, when he was promoted to the rank of full surgeon, and assigned to duty in Clark's Regiment of Texas Volunteers. He enjoyed the confidence and respect of his command, and served with distinction throughout the war. In the winter of 1864–5 he was detached and sent to Arkansas to examine conscripts, and did valuable service by ordering men to duty who had been exempted for some trivial cause. At the close of hostilities he returned to Sherman, and resumed the practice of his profession. He attended a course of lectures at the University of Pennsylvania, and graduated from that institution in 1868. He was appointed Superintendent of the State Lunatic Asylum at Austin in 1879 by Governor O. M. Roberts, and successfully administered its affairs for a little more than two years, when he resigned to return to his home in Sherman, and again engage in private practice.

He was a man of fine physique, with a commanding figure and vigorous intellect. He was an attentive reader, digested well everything he read, and was possessed of a wide fund of general information. He was popular both as a physician and citizen with all classes in his community, and especially so with the young men, in whose society he delighted. He wielded a marked influence both in political and social circles, although he manifested a lively interest in the political affairs of the country, was never a candidate, and never held political office. He always commanded a good practice, was exceptionally well informed in the general literature of medicine, and carried to the bedside a ripe judgment. Though a general practitioner he was a surgeon of no mean capacity, but the department in which he excelled was that of diagnosis, being an acute observer and good reasoner, he rarely committed an error in diagnosis. He commanded the respect and confidence of his professional brethren in a marked degree, was an able counselor, agreeable and just to all.

He was a member of the American Medical Association, was first Vice-President of the Texas State Medical Association in 1879, and presided at its meeting in that year, was several times President of his County Medical Society, and an active and influential member. He was President of the Board of Medical Examiners for his District, and a railroad surgeon for many years. He was considered a "landmark" in the community in which he resided, and will be missed throughout the State. His character was above reproach, of a chivalrous nature, humane and generous to a fault. His charitable acts were performed in such a quiet way they were known to but few even of his personal friends, and his genuine modesty was sometimes detrimental to his personal interests. The profession has lost an able and loyal member, the community a useful citizen, a kind neighbor and cultured gentleman. He leaves a widow and one son. The profession of his county held a meeting, passed appropriate resolutions of respect, and attended his funeral in a body.

MISCELLANEOUS.

Unsanitary Condition of Ohio's Capitol.—Dr. R. Harvey Reed, of Mansfield, O., Secretary of the State Sanitary Association, has made a sanitary examination of the State House at Columbus, O., for the *Sanitary News*, and makes the following report:

Through the kindness of the chief engineer of the capitol, Mr. James Semple, a master plumber of Cincinnati, together with an eminent plumber of Columbus, accompanied me in the first inspection made about two weeks ago. In the second inspection I was accompanied by Mr. William Halley, a master plumber of Columbus, and the chief engineer. The following conditions were especially noticed: The "new" water closets of the House are the "Jennings" closet with tank supply, and intended to have a downward draft for ventilating purposes, but upon testing, they proved to be without any draft, and no means of ventilation other than the theoretical "downward draft" referred to. The urinals used are the old fashioned ones made of porcelain and flushed with water. Drippings are taken up by a bountiful supply of sawdust scattered over the floor. The urinals are without ventilation.

We next went to what is known as the "old closet" of the House, which is an old fashioned closet without traps of any description, and which is intended to be cleansed by a meager supply of water from a "tank supply and after wash," but which fails very decidedly in its purpose. Here the ventilation is supposed to be the "downward draft system," which, a test showed a draft sufficient to carry quite large pieces of paper out from the closet into the room instead of downward. This draft is constantly supplying the building with poisonous sewer gas in unlimited quantities.

Here the urinals are the old style, lead lined, and without either traps or ventilators, and are ably assisting in the work of supplying the capitol with copious supplies of poisoned air.

The Senate water closets and urinals revealed the same deplorable condition as those of the House. On examining the flush tanks we found the overflow pipe connected with the sewer without either trap or ventilator, and, unless there should be a constant overflow to prevent it, there is an immense discharge of sewer gas which is sickening and revolting. These tanks are so situated in dark closets as not to be seen, but, by their location in the building, they are enabled to supply it with a bountiful supply of poisonous gas.

The main sewer of the capitol connects with the Broad street sewer, and is trapped with an S trap, and ventilated through the smoke stack, which is also intended to give a "downward draft" to the water closets, but which is a practical failure as it stands to day.

The building is heated with steam pipes and an attempt at ventilation is made by introducing fresh air from the outside and warming it by means of these pipes in suitable brick chambers, and then carrying it through the building. The foul air is intended to be taken from these rooms in a similar manner and emptied into the smoke stack. This plan, however, does not succeed in getting rid of the foul air, and direct ventilation by means of the windows is often necessary in both houses.

It was noticed that the joints in the "live steam" pipes were made non expansive, while the return pipes for the so called "dead steam" pipes were made expansive, which serves to illustrate some of the scientific principles applied in the State Capitol in the plumbing line.

The escape of sewer gas in the basement is so extensive some days as to sicken the visitor who attempts to go through that part of the building. On other days it is scarcely perceptible. The writer having been present in both of these conditions, is reliably informed that this condition depended greatly on the direction of the wind.

Strange to say, the sewerage and plumbing of the capitol, as originally designed by the architect and executed, has mysteriously disappeared.

An appropriation has been made of $1,000 to put in new water closets, which should include the proper sanitary plumbing of the same.

The lighting of both houses is extremely unsanitary, the members having to sit facing large windows with the light glaring in their eyes, which together with the foul poisons that have free access to the capitol by means of improper and defective plumbing and ventilation, would make one feel that it is only charitable to excuse them for accused bad legislation, if the remedy for this all did not lay within themselves.

National Conference of State Boards of Health.—There will be an Annual Conference of State and Dominion Health Authorities at Toronto, Canada, early in October of this year, and all State and Dominion Boards of Health are cordially invited to send delegates. It is the design of this Conference to consider questions of mutual importance to all sections of the country, and in order that delegates may fully understand the topics to be discussed, as well as to determine the time necessary to set apart for this work and not interfere with the regular exercises of the American Public Health Association, it is necessary that Boards of Health should formulate questions and propositions they wish to have considered, and send the same to the Secretary, at Concord, N H, before August 1, 1886 A programme will then be made and sent to the several State Boards so that delegates can be prepared to act without delay, thereby facilitating the work of the Conference

Please send all questions and propositions in exactly the form you desire them to appear in the announcement Also, send the names of your delegates

It is proposed to meet one or two days prior to the meeting of the American Public Health Association, and the length of the programme will decide the time Therefore, all papers, questions and propositions should be submitted in due season

G P CONN, *Secretary*

Concord, N H

A DANGER IN TOY BALLOONS —The *Lancet* says that it seems that the little toy balloons or Inda rubber bladders which children inflate with the breath may be readily reversed by inspiration and even drawn into the air passages In two instances recently death has occurred by suffocation, a balloon of the sort being drawn into the opening of the glottis This is a matter of danger which ought to be recognized Parents and nurses should be on their guard

REPORT BY M PASTEUR —At the meeting of the Academy of Sciences last week M Pasteur read the following report of the results of his anti-rabic treatment at his laboratory in the Rue d'Ulm "The number of persons so treated amounted up to the 12th inst to 726, including those who are still undergoing treatment Of this number there were 688 who were bitten by mad dogs and thirty eight by wolves, the latter being all Russians The patients belonging to the first category are, with the exception of the little girl Pelletier, who, it will be remembered, died after a few inoculations, all doing well More than half of that number have passed the dangerous period Of the thirty eight Russians who have been treated and are still undergoing treatment, three have died rabic, the others are doing well, but it is impossible to foresee what may happen to them, as there exists a profound difference between the bites of dogs and those of wolves, the proportion of deaths caused by rabid wolves being at least 82 per cent" M Pasteur then concluded his report in the following terms "The above facts demonstrate (1) that the duration of incubation of human rabies caused by the bite of a rabid wolf is often very short, very much shorter than rabies after the bite of a mad dog, (2) that the mortality after the bites of rabid wolves is considerable if we compare it with the effects from the bites of dogs These two propositions may be sufficiently explained by the number, the depth, and the seat of the bites caused by the wolf, which so savagely attacks his victim, the attack being often on the head and face The necropsy of the three Russians who died at the Hôtel Dieu, and the inoculation of rabbits, guinea-pigs, and dogs with the medulla oblongata of the first of the patients who died, prove that the virus of the wolf and that of the dog are sensibly of the same degree of virulence, and that the difference of the rabies of the wolf and that of the dog depends on the number and nature of the bites These facts induced me to inquire whether, in the case of bites from rabid wolves, the method could not be usefully modified by inoculations in greater number and within a shorter time The results will be eventually reported to the Academy In any case, for the wolf in particular, it is good to submit the patient to the preventive treatment as soon as possible The Russians of Smolensk were six days on their journey to Paris, and presented themselves at the laboratory fourteen or fifteen days after having been bitten They might therefore have commenced the treatment eight days earlier, and one can not say what might have been the influence of this modification for the three patients who have succumbed"—*The Lancet*, April 24, 1886

A RICH merchant, M Chludow, has left more than £100,000 and a house to found a children's hospital in Moscow —*The Lancet*, April 24, 1886

THE PANAMA CANAL —M de Lesseps, who has recently returned from Panama, read a paper at a late meeting of the French Academy of Sciences giving an account of the progress of the great canal works The sanitary condition of the workmen he described as "relatively good," contrary to the unfavorable prophecies which were freely uttered at the outset In a hospital with 500 beds, M de Lesseps found only 300 occupied —*Lancet*, April 24, 1886

M VULPIAN has been elected Secretary for life to the Academy of Sciences, in place of M Gamin, recently deceased

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY FROM APRIL 24, 1886 TO APRIL 30 1886

Capt Joseph K Corson, Asst Surgeon granted ten days' extension of leave of absence granted in Order No 79, April 15, 1886, Jefferson Bks, Mo (S O 97, A G O, April 26, 1886)

Capt Wm J Wilson, Asst Surgeon (Plattsburg Bks, N Y), granted leave of absence for one month, on surgeon's certificate of disability (S O 25, Div Atlantic, April 27, 1886)

Capt Robert B Benham, Asst Surgeon, ordered from Dept Texas to Dept Dakota (S O 97, A G O, April 26, 1886)

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U S NAVY DURING THE WEEK ENDING MAY 1 1886

Wieber, F W F, Asst Surgeon, detached from R S "Vermont" and ordered to the "Hartford"

Tracy, Elmer C, Asst Surgeon, ordered to the "Vermont"

Waggener, J K, P A Surgeon, detached from the "Hartford" and ordered to the "Iroquois"

Bransford, J F, Surgeon, detached from the "Iroquois" to proceed home and await orders

Kite, Isaac W, Asst Surgeon, to duty at Naval Hospital, Brooklyn, N Y

ADDRESS IN MEDICINE

SOME POINTS IN BACTERIOLOGY[1]

BY JAMES T WHITTAKER, M D,
OF CINCINNATI
PROFESSOR OF THEORY AND PRACTICE OF MEDICINE, MEDICAL COLLEGE OF OHIO

> *"Vere scire est per causas scire*
> —BACON

There are three planes in the history of medicine The first is the study of the symptoms or appearance of disease It is the period of the infancy of medicine It is naturally the most crude period, and all irregular medicine still rests upon this plane It gave us a pharmacopœia, and the highest expression of it made of the practice of medicine an art The second plane begins with the observation of the effects or lesions of disease It made us familiar with the natural history of disease, and thereby nearly destroyed the pharmacopœia The third is the present plane, upon which are being prosecuted investigations into the cause of disease Investigators have just set foot upon its threshold When it shall have been fully attained medicine will be entitled to a place among the sciences which are called exact

The progress made in this direction during the past year so completely overshadows all other work in range and promise of practical value as to justify in this report, to the exclusion of everything else, a brief review of the conclusions reached

The etiology of acute infections is comprised under the single term, *bacteriology*, the bacterium having come in the course of time to include all pathogenic as well as many innocent micro organisms

The year just passed has not been as eventful in the definite discovery of new causes of disease as several that have preceded it in the first half of the present decade What has especially characterized the past year is the fixation of facts previously acquired, whereby the so called germ theory of infectious disease has been brought from the realms of the ideal to the region of the real Coemans said several years ago, "the following up of a single bacterium through all its phases of development is far more valuable than the discovery of new germs," and this pursuit has now been made with such success in the case of many forms as to justify in our day the claim of Magni in the Roman Annals of Public Medicine, fifteen years ago, that the study of medicine should undergo a reform, making obligatory at least a three months' course with micro organisms

For it is now demonstrated beyond dispute that pathogenic micro-organisms do exist in distinct and definite entity The views advanced by Beale, that bacteria are portions of diseased protoplasm from living tissues, and by Wigand, that they may spring up *de novo* in organic matter by transformation of organic molecules, are no longer held worthy of serious consideration The view of Beale was never anything more than an ingenious hypothesis, and it fell to the ground with the first studies of the life history of bacteria, while Wigand's theory had no better support than any other *spontaneous generation* The fate which so quickly overtook the illustration of this theory may well serve to show the danger of advocating spontaneous generation in our day

Wigand remarked that for the purpose of dissipating all doubts concerning the spontaneous development of bacteria in the protoplasm of cells, he would call attention to the fact that moving bacteria could be seen at any time in the healthy living cells of the trianea bogotensis, and in the hairs of the labiatæ. This statement was brought to the notice of the eminent botanist of Strasburg, de Bary, who thus describes his investigations The trianea is a South American floating water plant A piece of its living tissue removed from a fresh, healthy plant, examined under the microscope, reveals in fact the most exquisite picture of bacteria Slender bacilli, alone or adherent in short rows, follow about the movements of the protoplasm and other contents of the cell in the liveliest way Such a picture is a model—as a picture But the addition of a drop of dilute nitric acid quickly dispels the illusion Instead of maintaining itself like a true micro-organism, the bacteria of the trianea are dissolved away at once The same is true of the rods in the hairs of the lip flowering plants The "bacteria" are nothing else than small crystals of oxalate of lime frequent in this form in the cells of plants This story is instructive, the author says, in showing how far astray preconceptions may lead otherwise excellent observers

Wigand saw micro organisms develop in fluids after exposure to boiling heat for half an hour, a temperature and time sufficient, he thought, to destroy all germs But the experiments at Koch's laboratory at Berlin prove that individual spores resist a boiling heat for several hours Wigand's erroneous conclusions were based upon an imperfect sterilization

---

[1] The Address of the Chairman of the Section of Practice of Medicine, Materia Medica and Physiology at the Thirty Seventh Annual Meeting of the American Medical Association St. Louis May 5 1886

What a contrast to these obscure conceptions is offered in the clear statements of Leeuwenhoek, the first individual to turn the lens, crude and imperfect as it then was, upon, and to discover, micro organisms. It would almost seem as if great minds knew intuitively what is true and what is false, else how may we understand the observation made by Leeuwenhoek as early as 1685 of the minute organisms found in water: "they do not arise in the water," he says, "they develop from germs."

The germ theory of disease was never really in so much danger from its enemies as its friends. For many years it suffered ridicule and discredit because of the false conceptions of "undismayed pioneers" and over zealous advocates. The Germans still speak of the "uberreifer Eifer" of this class. Thus the choleraphyton proclaimed in England, and later again in Germany, turned out to be nothing else than eggs of intestinal worms, the animalculæ of variola eventuated in the common bacteria of putrefaction, and the palmellæ of malaria disclosed by one of our countrymen were unmasked as foreign bodies, impurities, not even germs.

Claims of Convertibility of all Germs.—An original conception of this over ripe zeal was the view of Hallier, that all kinds of germs, big and little, moulds, ferments, bacteria, are mutually convertible. Micrococci, said Zurn, are only stages of development of moulds. This view needed only the most accurate observations of Brefeld and de Bary to be entirely refuted. More serious was the claim of Grawitz that innocent mould fungi, aspergillus, mucor, etc., could be converted into dangerous forms. Grawitz saw that the injection of aspergillus into the blood of rabbits remained without effect, whereupon it occurred to him to change its natural, cool, acid soil to a warm alkaline soil with a view of changing its form and action. Such general permeation of various internal organs, especially the kidneys, followed these experiments, as to seem to have demonstrated the conversion of the innocent into a dangerous parasite.

But when Koch and Gaffky came to repeat these experiments, with the precautions implied in control observations, it was soon discovered that the species of aspergillus, mucor, etc., included a whole series of pathogenic germs, some of which had entered with the injection of innocent forms. Grawitz's erroneous conclusions were based upon the use of impure cultures.

The field had now become limited to the bacteria proper. It may be said at once that all practical interest hinges upon the question of the constancy or inconstancy, *mutability or immutability*, of the forms of pathogenic micro organisms. If they are not specifically different, as Nageli claimed, but are forms of one or a few species, so that the same species, by assuming different forms, may, in the course of years or decades, effect at one time the souring of milk, the ageing of wine, putrefaction, the decomposition of urea, the red coloration of starchy food, and at other times produce typhus, malarial or relapsing fevers, diphtheria and cholera—if such mutability of form and action exists as this, if the myriad micro organisms of the earth and air may at any time assume deadly properties—all effort at investigation is futile, if not foolish, and every effort at destruction is not only powerless but paralyzed.

This idea of the unity of species, first advocated in our day by Ray Lancaster, met with warm advocacy at the hands of Billroth, who derived the different forms from variations in the soil or substratum, and later of Warming, who considered the different forms as so many different stages of development of the same species, like, to use a coarse comparison, the different stages of development of tapeworms in different hosts. Klebs was also inclined to accept this view, though with the reservation that certain forms occur preferably in the form of bacilli, others of micrococci.

Hay and Milzbrand Bacillus.—Perhaps no single statement seemed to lend such support to the negation of species as the claim of Buchner to be able to transform the innocent bacillus of hay infusion into the deadly organism of milzbrand. Buchner observed under continued cultivation the gradual change of the hay bacillus into the milzbrand bacillus, and with the reversal of this change, which he was likewise able to produce, maintained that the loss of virulence of the milzbrand bacillus was not an attenuation, as Pasteur had claimed, but a veritable transformation. Buchner was sufficiently well acquainted with the gross differences of the two bacilli, but he regarded them as accommodations of the same form to different soils. Hueppe credits Buchner also with a knowledge of the spore formation of the two bacilli—the most distinctive characteristic of different forms—which Buchner considered identical, a consideration which misled Brefeld to adopt Buchner's conclusions, but de Bary insists that with the gross differences in the spore formation of the two bacilli, it is doubtful if Buchner ever really studied the hay bacillus in this essential particular.

At any rate, it was easy for Koch, by pointing out these differences, as well as the difference in the resistance of the spores, the difference in the optimum and minimum temperatures in the process of reproduction, etc., to prove that Buchner was experimenting with two distinct species or forms, and that the apparent transformation was really a case of substitution or displacement of one form by the other. Inasmuch as no one has since succeeded in effecting such a transformation, this question may be regarded as definitely settled. Final disproof of Buchner's claim was made by Prazmowski in 1884, with the exhibition of such distinct differences in the two forms as to demonstrate their independence, so that whatever dispute remained concerned simply the possibility of attenuating the bacilli of milzbrand, a subject to be noticed again.

Bacteria of Milk.—A much more simple and easily refuted illustration of the inconstancy of action of micro organisms was the observation of Nageli, that fresh milk on standing becomes sour but boiled milk bitter. Fresh milk becomes sour, Nageli says, under the action of a certain bacterium. Boiling the milk changes the character of the soil and the action of the same germ. Here, then, is an everyday observation of the transformation of the same micro organism

That this illustration may not seem too trivial, it may be said that it was, up to the time of Buchner's experiments, just mentioned, the sole apparently indisputable proof of the change of one definite ferment into another

The fallacy of it became obvious when it was discovered that milk is made sour by many causes, among others, by many varieties of bacteria, of which Nageli assumed the existence of but one It did not occur to him to inquire if one variety might not get the upper hand before, another after boiling The truth turned out even more simple than this, for Hueppe showed that of the many forms of micro organisms present in milk, one, the micrococcus lacticus, exuberates in a low temperature, and renders milk sour by the formation of lactic acid Boiling kills this micro organism with many others, but the spores of the butyric acid germ, the bacillus amylobacter, also present, survive boiling heat to develop later into the mature form This bacillus effects in boiled milk a decomposition of the albuminates, attended with a bitter taste Neither form nor action has been changed in a single germ

Deviations that do Occur—But the strongest advocates of constancy of form and function, Cohn and Koch, do not maintain that certain deviations may not occur They claim only that these deviations occur within certain limits, such limits as are to be observed in structures higher in the vegetable scale Gardeners, florists, farmers, succeed in effecting, under varying surroundings, marked variations from he primitive plant, but they may never change an apple to a pear tree, wheat into rye, or a sunflower to a rose Koch himself admits the possibility of changing one form of micro organism to a nearly allied form He goes so far as to say that it is not without the bounds of possibility to convert a pathogenic into an innocent form What he asks is simply that the specificness of one form shall not be surrendered until the proof is furnished There are monomorphous and pleomorphous bacteria No one claims that every micro organism shows itself under all circumstances in but one form, as Koch admits the occurrence of Finkler's vibrio in three forms, the curved rod, the lemon shape and the spirilla, but he still insists that the individual preserves the reproductive form of its cells, that is, that it appears as a micrococcus, a bacillus or a spirilla, and that it does not change these forms For, as Mittenzweig maintains, it has never yet been shown that a bacterium appears at one time as a genuine micrococcus, at another as a genuine bacillus, and again as a genuine spirilla, and even if we admit the form changes which Buchner and Gruber have observed in the organism of Finkler, and Babes has observed in the cholera germ, we must also admit, as Buchner has himself observed, that in the cultivation of the different forms the typical curved rod invariably appears, so that all these secondary changes are to be looked upon simply as so many variations upon the typical form With the experience of the botanist and florist cited, it is not a matter of surprise that micro organisms have been seen to undergo changes of form which are not observed in nature Attenuations of virulence, for instance, in virulent germs never occur spontaneously

The Germ, not the Form, Essential—The conclusion reached by the mycologists of the present day is that under natural circumstances micro organisms show themselves in the rule, not with variations but in permanent forms, but that disease is not produced so much by a distinct and definite form as by a distinct and definite germ Most of the diseases of plants, de Bary says, are produced by parasites, and as investigations develop more and more distinct species it is seen that definite diseases are produced by definite parasites, whose specific properties are no more to be doubted than those of higher organisms or worms This claim, the author concludes, is not simply convenient, as Nageli observes, it is the only view which is consistent with acquired facts

Ubiquitous and Indigenous Germs—The world of micro-organic life falls naturally into two great divisions One is found everywhere, at all times and in all places, and, as has been shown, in abundance enough to realize the panspermatism of the ancients Such germs are known as omnipresent, or, from the fact of their ability to obtain sustenance everywhere, as omnivorous germs Hallier proposed to call them cosmopolitan, but Cohn devised the best appelative when he spoke of them as ubiquitous Myriads of these germs are entirely innocent to man Others are injurious only under certain circumstances Thus the ubiquitous germs of common putrefaction may penetrate the body from a slough or a gangrenous part, to produce by their presence, or the chemical changes they induce, the condition known as septicæmia Thus the pus producing micro organisms, probably of many kinds, belong to the class of ubiquitous germs

On the other hand, most pathogenic micro organisms are indigenous to certain definite places These are the epidemic germs Thus the mouths of the Ganges and Brahmaputra are the centres of cholera, Lower Egypt of the plague, the Antilles of yellow fever, Ireland of typhus But just as plants of higher organization may be transplanted to other soils, may original endemics assume epidemic and finally pandemic proportions or extent Thus small pox first showed itself in Germany in 1493, an importation from the Netherlands, but it was not until 1527 that it was transported to our continent, making its appearance with wholesale slaughter in Mexico, and gradually extending thence over the whole of North America. Scarlet fever, which was first heard of in Arabia, was not seen in our country until 1735 It reached Iceland in 1827, South America in 1829, Greenland in 1847, and Australia in 1848 Measles had not been carried to Australia up to the beginning of our own decade Cerebro-spinal meningitis, in all respects the most irregular of all epidemic diseases, first sprang up in Geneva, and first fell upon our country in 1806 Cholera was unknown with us until the memorable year of 1832 Even tuberculosis, which has long since assumed pandemic extent, was, as Liebermeister has shown, not originally ubiquitous, as it remained unknown to our own Indians, to the aborigines of Australia and the negroes of Central Africa until carried to them by more civilized races There is therefore no longer question of the spontaneous, or so-called autocthonous, origin of infection. Typhoid and typhus fevers, dysentery and diphtheria, pyæmia, erysipelas and puerperal fever, appear only at times when lurking germs and spores from previous cases find favorable conditions for development, or after fresh importations of the disease. All this disease, all infectious disease, is of exclusively parental birth, and can no more originate spontaneously than can serpents and crocodiles originate from heat and mud as Lepidus maintained, bees be produced from the putrefying entrails of steers, as Virgil described, or mice be generated from sawdust and old shirts, as Van Helmont claimed. In keeping with these theories were the views since maintained that the plague arose from the putrefaction of corpses, yellow fever from the crowding of slave ships, cholera from decaying vegetable food, typhoid fever from the emanations of human excrement, consumption from bad ventilation, or oftener from a bad cold, and diphtheria from sewer gas. These are factors which do undoubtedly favor the spread of the infectious maladies, but never originate the birth of one. A fright may cause a premature birth, Jurgensen remarks facetiously, but it would never conceive a fœtus. So, rabies and hydrophobia can no more arise spontaneously than can dogs and men.

Thus is explained the specificness of acute infectious disease. Each one of these diseases produces itself alone. Measles begets measles, small-pox begets small-pox, cholera begets cholera. Figs would be born of thistles, or grapes of thorns, as soon as cholera of small-pox or diphtheria of typhoid fever. The introduction into the blood of a specific germ begets the specific disease, and the fact that each one of the acute infections has always presented the same characteristics, proves most conclusively that *no change has occurred* in the properties or peculiarities of the specific cause. For so long as observations have been recorded, measles, for instance, has always been the same disease, with the same period of incubation, the same prodromata, and the same eruption, the same complications and the same termination. New interpretations of the phenomena of the acute infectious diseases have been made from time to time, more searching means of study have developed new signs, but the characteristic features of each of the acute infections have always remained the same. The accurate observations rendered possible by the adoption of the solid culture soil are in thorough accord with these conclusions. The essential nature of pathogenic bacteria is not changed by alterations in the soil or other surroundings. Bacteria may be shriveled or dwarfed or reproduction checked by lack of oxygen, unsuitable nutrition, improper temperature, but they may not be changed in nature. Up to the present time it has been found impossible to convert innocent into pathogenic forms, and the observations recorded which seem to lend support to the transmutation theory, as by Buchner, Bastian, Nageli, and others, have been shown to rest upon inaccuracies or impurities.

Attenuation not Change of Nature.—But the case is very different with the converse of this view, which opens up one of the most interesting studies in mycology. Is it possible to deprive the pathogenic forms of their pathogenic properties? The belief is still maintained, by some clinicians at least, that vaccinia is smallpox which has lost its virulence by passing through the body of a cow, and the question of attenuation of the so called virus of virulent disease with the view of inoculating it in milder form, occupies the attention of prominent mycologists at the present time. Within the present decade this question has been answered in the affirmative with reference to the virulent bacteria of charbon. For it has been discovered by Pasteur and by Koch that under the influence of high temperature and various chemical agents, the bacteria of charbon may be made to suffer loss of their pathogenic properties, while they still retain all other characteristics, including the capacity of reproduction. Pasteur claims to have effected the same attenuation in the case of hydrophobia. But these observations do not support the view that any change of nature has been experienced in this way. Bacteria thus treated are not changed into innocent forms. They have simply lost the physiological property of infection. Baumgartner puts it pertinently when he says it is not a question of changing poisonous into innocent snakes, but of extracting the poison fangs from animals which otherwise remain the same.

The Morphology of Bacteria is not simply a question of size and shape. The term is extended to include also motion, color and affinity for color, as well as the manner of growth or disposition of the colonies. In many cases such distinctive peculiarities are already demonstrated as to render it possible to absolutely diagnosticate disease in life by one or more of these points. As Hueppe says, this is the most interesting question for the clinician. May we make a differential diagnosis from morphology alone?

Bacteria vary greatly in both length and breadth, but are for the most part so small as to be on the confines of the visible with the microscope. In fact, it is chiefly by reason of the recent improvements in the illumination and magnification of the microscope, the oil immersion lens and Abbé illuminating apparatus, that they have been rendered visible at all. Some of them are to be seen only with a power of 700 diameters, which is the magnification generally used in the study of all micro organisms. Mycologists speak of micro-, meso and mega coccus, or bacteria, of the micrococ coccus prodigiosus, and of the bacillus subtilitis, but these are all, of course, relative terms. Pathogenic micro organisms vary in length from 1 to 40 mikro millimetres, and in breadth from 0.5 to 7mm. Many micrococci are to minute to admit of any accurate measurement. The largest micro organism is the spirilla, which may reach the length of .2 of a millimetre. Perhaps a better idea of size can be conveyed by comparison with a familiar object. The bacillus tuberculosis, which occupies in respect to size a median place, varies in length from 1–2000 to 1–3500 of an inch, the smaller measure being the average diameter of a corpuscle of human blood.

Although some distinction may be made between pathogenic and innocent organisms by their size and shape, the most skilful mycologist would hesitate to express an opinion on this fact alone. But micro-organisms may look alike and yet be very different Spermatozoids of different animals may present the same general appearance, but they are endowed with very different properties We remain as yet at too great distance to make out the distinguishing features even of innocent and dangerous micro organisms As Birch-Hirschfeld remarked, it would be impossible to declare of a man standing on the spire of the Strasburg cathedral, whether he was black or white, and even the same configuration in every particular would furnish no more definite criterion than in the case of full grown serpents of the same appearance, some of which only are poisonous We await now with intense interest the revelations which are to follow the experiments with the new theory worked out by Professor Abbé, which it is claimed already exhibits differences in the structure of bacteria

The general construction of bacteria, so far as it can be studied, is simple enough Bacteria are cells because they are constituted, grow and divide like cells, and although nuclei have not yet been discovered in them, they are in this regard not unlike other low forms of vegetable cells The protoplasm of the cell seems homogeneous in the minutest, but more or less granular in the larger and more distinctly visible forms It shows the same reactions and takes up the same colors as other protoplasmic bodies, differing as they do in different forms The cell is invested with a membrane which may be separated from the protoplasm by agents like the alcoholic solution of iodine, which shrink the protoplasm The membrane assumes prominence also at the period of spore formation It is in most cases firm and closely apposed to all contents, while in the spirochates it is extensile and elastic Dark, transverse lines forming across the protoplasm indicate the division of a bacterium into daughter cells, which separate in the process of reproduction Hence the name schizomycetes A billiard ball, a lead pencil and corkscrew, indicate in the homely comparisons of de Bary the chief varieties of bacteria as micrococci, bacilli and spirillæ

Distinction of Bacteria —A glance would reveal the difference between a bacillus and a spirilla, and there could be no question of mistaking a micrococcus for either In many cases even gross morphological resemblances could create no embarrassment in the mind of the practitioner What possible doubt could exist, for instance as between the comma bacillus of the stools and intestinal contents of cholera and the innocent comma bacillus found in the mouths of healthy people? The condition of the patient decides it at once, or if there could still be a doubt, it would be dissipated with a knowledge of the fact that the cholera bacillus is not found in the mouth But in many cases differences in form alone are too slight, and variations in size too great to be recognized by the clinician In some cases these differences can be seen Thus the slight deviations between the forms of the bacilli of milzbrand and malignant œdema enable mycologists to separate diseases which are often confounded But these distinctions may be made out only in the laboratories of experts Hence for practical use appeal must be made to other factors in morphology Thus the bacillus of tuberculosis, syphilis and leprosy closely resemble each other, that is closely to the clinician, though coarsely to the mycologist But the tubercle bacillus distinguishes itself from all other bacilli save one, by two peculiarities first, lack of affinity for all dyes, that is, the resistance it shows to colors, and, secondly, when it is colored with alkaline dyes, by the persistance with which it retains its color in the presence of mineral acids This persistence is shown only by the bacillus of leprosy, but the bacillus of leprosy may be differentiated by the fact that it may be colored with Weigert's nucleus color, (hæmatoxylin, alcohol, alum, aa 2, distilled water, glycerine, aa 100), which has no effect upon the bacillus tuberculosis The colored bacilli of syphilis are decolorized by mineral acids By the method mentioned Gaffky discovered characteristic bacilli in the sputum of tuberculosis in 938 of 982 cases

Considering the fallacies of the observations, and the stage of prephysical signs, it is safe to say that the time is close at hand when we shall no longer think of using the pleximeter and the stethoscope in the diagnosis of tuberculosis

A skilled mycologist would alone detect the fine differences in morphology of the bacilli of cholera and cholera morbus, but any one would notice at a glance the difference in the funnel and cone or stocking shaped colonies of the two varieties As, however, the length of time that must necessarily lapse to make this observation precludes its practical value to clinicians, quicker conclusions can be reached by the physiological test, that is the introduction of the germs, or matter containing them, into the stomachs of guinea pigs These animals are very susceptible to cholera morbus, but insusceptible to true cholera, without special preparations or precautions ' Perhaps this test would be resorted to only in cases where doubt existed as to the commencement of an epidemic of Asiatic cholera

The method in which the bacteria aggregate themselves in the process of growth in the culture soil, the process of colonization it would be called in the tissues of the body, or *the formation of zooglea*, furnishes some, but uncertain information regarding the nature of the germ Cohn thought at one time that the whole class of bacteria might be divided into two distinct species, one of which formed a mucus-like mass, the other fibrils or threads These classes he proposed to designate as gleogenous or mucus-forming, and nematogenous or thread forming families, but he was compelled subsequently to abandon the idea on observing the changes in the mode of growth in different soils and at different temperatures Thereupon Koch observed that the formation of zooglea in the form of membranes or fibrils, squamous, dendritic, fenestrated, nodular, globular, circular, etc , immediately preceded the development of spores Both Cohn and Koch soon reached the conclusion that while the form of the colony might serve to separate families and groups, estimates based upon such observations must be accepted with much reserve But while it is admitted that the form of the zooglea varies in different soils, it is nevertheless true that a typical form is shown under the same conditions, a fact which Hueppe remarks, essentially lightens a differential diagnosis To give but one example, the bacillus anthracis may be macroscopically distinguished from the non parasitic bacillus subtilis by the fact that the anthrax bacillus forms in its soil a flocculent deposit, while the bacillus subtilis develops a dry membrane upon its surface

The development of bacteria does not differ from the higher vegetations in requiring the necessities of life, food, heat, oxygen, water, etc

Pure Culture Soils —The question of food is connected with the subject of cultivation in the so called pure culture soils, which consists in selecting the food best adapted for the rapid multiplication of micro organisms The fact that bacteria remain sterile in certain soils and luxuriate in others does not surprise us when we reflect upon the predilections of higher forms of vegetation

While, then, many bacteria may be cultivated in almost any kind of culture soil, they differ in the degree of development according to the nature of the soil Thus Wilkommen has observed that the germs which thrive upon the South American potato can not be made to grow upon the European potato The micro organisms which give the peculiar piquancy to Stilson and Roquefort cheese grow better in certain cellars than in others The first experiments in cultivating bacteria were in fluids, solutions of meat, beef tea, chicken soup, malt extracts, infusions of hay, etc , but fluids are open to the objection that they admit other germs, to coalesce with and rendered impure the special variety to be studied Pure cultivation became possible only with the use of the pure culture soil, first employed by Koch Germs falling upon a solid surface remain fixed in the same place The solid culture soil made practicable the absolute isolation of germs, without which accurate investigation is impossible Koch made his first studies with the common potato The potato was the key to the whole subject of solid cultures We might say that what the apple was to Newton the potato was to Koch Subsequently gelatine was employed, then aqueous humor, then gelatinized meat preparations, peptonized gelatine, etc , and as a climax for the epicures, gelatinized blood Thus has been determined the peculiar soil in which the varieties of pathogenic bacteria thrive the best Thus while the bacillus of both forms of cholera develop upon both animal and vegetable soils (both being really exanthropic germs), the bacilli of tuberculosis will not grow in a vegetable soil as upon the surface of a potato, but will thrive in infusions of meat and luxuriate in the serum of the blood The micrococcus of chicken cholera grows to swarms in neutralized chicken-soup, and the comma bacillus, which is really not a bacillus, but a form of vibrio or spirilla, develops in such luxuriance in alkaline meat soups as to have enabled Schottelius to detect it in minimum amount In such cases, where but very few or doubtful specimens were present in the intestinal contents, Schottelius added to the contents two and a half times as much slightly alkalised infusions of meat, or ten times as much gelatinized meat peptones In this mixture preserved uncovered in a warm place at a temperature not above 40° C cholera germs developed in myriads within twelve hours

Effect of Bacteria on Food —In this connection a remark may be made upon the effect of bacteria upon the food selected, foreshadowing the local effects of micro organisms upon the tissues of the body in the so called local symptoms of disease It is observed and distinctly tabulated if the gelatine or other food be fluidified, granulated, colored, decomposed, with or without the development of odors and gases, and the time required to induce these changes Thus have the mycologists made us familiar with characteristic features of the vibrios of both forms of cholera, which fluidify gelatine, while the micrococci of pneumonia have no such effect, have pointed out the nail cultures of pneumonia, the air vesicles of Asiatic cholera, the flat scales of tuberculosis, the fern leaves of the micrococcus of erysipelas, the acacia leaves of one form of the micrococci of pus So also of the effect of puncture or stick cultures show peculiarities different from plate cultures, and different effects are observed again with the same bacteria in different kinds of soil or food Eisenberg has recently (Hamburg and Leipsic, 1886) published a Bacteriologische Diagnostik, which consists of a series of tables wherein are noted, in a form of inestimable value to the student of bacteriology, all these peculiarities of all known germs

Concerning Temperature —Three cardinal points are recognized of the temperature the maximum, the minimum and the optimum The optimum is the temperature most conducive to fructification, to spore formation Excesses in either direction arrest certain processes, extremes destroy life As might have been premised, non parasitic enjoy much wider latitude than parasitic germs Thus, according to Cohn, the bacterium termo grows between 5° and 40° C , with its optimum at 30° to 35° C , while the border temperatures of the bacillus tuberculosis, according to Koch, are 28° and 42°, with an optimum at 37°, the temperature of the human body The conjoined influence of soil and temperature is shown in the conduct of certain bacilli (tyrothrix) found in cheese The optimum temperature of this germ is 25° to 35° C In a neutral fluid they are killed by a temperature of 90° to 95° C , while in a weak alkaline fluid they live at 100° The mature spores of this species remain productive in a weak alkaline fluid after being boiled at a temperature of 115° C Tyrothrix filiformis survives in milk a temperature up to 100° C , a degree fatal in one minute in an acid fluid The spores of this species survive in milk a temperature of 120° C , while in gelatine they are destroyed at 110° C This knowledge of the range of temperature gives a differentiation at once of parasitic from non parasitic bacteria, as germs whose range is limited to 28° to 42° C , may not constantly find anywhere upon earth, outside of animal bodies, the necessary means of existence

Need of Oxygen —Such differences prevail regarding the need of oxygen that Pasteur separated all micro organisms into two classes, ærobes and anaerobes As, however, all known pathogenic micro organisms must have oxygen more or less, the division is of more value to the mycologist than the clinician One point in this connection regarding the ammoniacal degeneration of urine is of interest to the practitioner

Bacteria of Urine —This degeneration, as is well known, results from the conversion of urea by the absorption of water, into the carbonate of ammonia, during which process the originally clear fluid becomes cloudy and opaque A drop of this urine under the microscope discloses myriads of germs of all descriptions Cohn has shown that one of them, the micro cocus ureæ, is the prime cause of the ammoniacal change Pasteur had already discovered that this micrococcus cultivated pure in a fluid containing urea induced in it the same change as in urine, and Musculus has since disclosed the fact that the change is induced by a chemical product, an enzyma separable by alcohol, excreted from this particular germ

The presence of oxygen is a necessary condition of the life of the micrococcus ureæ, which cannot, therefore, be the cause of the ammoniacal degeneration that in bad cases of catarrhal inflammation takes place within the bladder, a sac shut in from the outside air It was then assumed that this degeneration must be affected by other anærobic bacteria, and in fact, minute forms are found in freshly voided urine

It is interesting to know that Miquel discovered in dust a very delicate bacterium which vegetates in the absence of oxygen This bacillus he named the bacillus ureæ, because it has the power of converting urea into the carbonate of ammonia Hence the force of Teuffel's warning, "Put no soiled catheter into the bladder"

The Fecundity of Micro Organisms has been so often demonstrated in explanation of the suddenness of appearance of them in multitudes, and of the virulence of infectious disease, as to require mention here only for the purpose of checking the riots of the imagination It is known that a particle from a milzbrand bacillus, so small as to be invisible under an ordinary lens, introduced beneath the skin of a guinea pig, multiplies sufficiently to kill the animal in forty-eight hours, and a drop of the blood of the animal thus affected, properly inoculated, destroys the largest ox in a few days It is useless to dwell upon this point of propagation It was the recognition of it that more than another compelled the return to the germ theory of infectious disease when it seemed to have been routed even with contumely No purely chemical substance possesses this property The power of reproduction or self multiplication is limited to living things Chemical substance admit of great subdivision, as best exemplified, perhaps, in the dissemination of odors, but such subdivision is attended always with gradual loss of substance

Reproduction takes place in bacteria, whether by fission or spore formation, a rapidity bordering on the marvelous Cohn indulged himself in the pursuit of a calculation, reaching the conclusion that the progeny of a single bacterium, unchecked in growth, would in the course of three days reach the apalling weight of fifteen million pounds Troy, and in five days fill up a space of 928,000,000 cubic miles, the estimated capacity of the entire ocean But while some such calculations may be justifiable to convey some adequate idea of the degree to which the earth and the air may be filled in a few days during the prevalence of an epidemic, it must be remembered that it was flights of fancy like these that first brought the germ theory into discredit and derision Check is put upon the development and reproduction of all bacteria by the lack of nutrition, which sooner or later must ensue, as well as by the inimical action of different varieties upon each other Thus the bacteria of decomposition cease to multiply and perish by the myriad so soon as the material of their food is converted into inorganic matter, the bacteria of fermentation are destroyed, or their reproduction checked by the alcohol which they form, the bacteria of cholera with dessication, etc The bacteria of most diseases perish with the death of their host, as well as from various other causes in life, as by the fever they evoke, or are themselves destroyed by the bacteria of putrefaction

Thus it has been proposed to cure trachoma with the gonococci of gonorrhœa, lupus and epithelioma with the micrococci of erysipelas, and tuberculosis by the inhalation of the bacteria of putrefaction

Spore Formation —The conditions affecting the process of fructification are of extreme importance to the proper understanding of the cause and prevention of acute infectious disease A single bacterium is made up of several cells of parts, of which each cell forms one spore Pasteur first recognized these "brilliant corpuscles," but it remained for Koch to determine their significance, and for Prazmowski and Hueppe to establish their supreme value from the point of view of differential diagnosis The difference in the method of spore formation is also a chapter of itself which could find no discussion in the limits of this report It is enough to say here that characteristics of specific bacteria are as definitely determined in the observation of these phenomena as in the effects of inoculation Spores constitute the permanent forms

Endospores and Anthrospores —There is now quite general acceptance of de Bary's division of all bacteria into classes, one multiplying by endospores and one by arthrospores Endospores are spores evolved from protoplasm in the body of bacteria in such a way that the spore forms its own membrane, while an arthrospore is a transformation of an entire part or cell of a bacterium, the membrane of the bacterium forming the membrane of the spore True bacteria develop by endospores Such are the pathogenic bacteria, whether in the form of micrococci, as of erysipelas, pneumonia, gonorrhœa, suppuration, bacilli, as of tuberculosis, syphilis, leprosy diphtheria, milzbrand, glanders and typhoid fever

Spores are distinguished from micrococci by their bluish, opalescent cast, their high refractive power, and their obstinacy to color, because of the impermeability of their membranes Strong acids and extreme heat, which kill the protoplasm of the bacteria, injure the vitality of the spore membrane, to make it permeable and admit color Under such conditions spores may be colored intensely while the body of the form is shown under the same conditions, a fact which Hueppe remarks, essentially lightens a differential diagnosis. To give but one example, the bacillus anthracis may be macroscopically distinguished from the non parasitic bacillus subtilis by the fact that the anthrax bacillus forms in its soil a flocculent deposit, while the bacillus subtilis develops a dry membrane upon its surface.

The development of bacteria does not differ from the higher vegetations in requiring the necessities of life, food, heat, oxygen, water, etc.

Pure Culture Soils.—The question of food is connected with the subject of cultivation in the so called pure culture soils, which consists in selecting the food best adapted for the rapid multiplication of micro-organisms. The fact that bacteria remain sterile in certain soils and luxuriate in others does not surprise us when we reflect upon the predilections of higher forms of vegetation.

While, then, many bacteria may be cultivated in almost any kind of culture soil, they differ in the degree of development according to the nature of the soil. Thus Wilkommen has observed that the germs which thrive upon the South American potato can not be made to grow upon the European potato. The micro organisms which give the peculiar piquancy to Stilson and Roquefort cheese grow better in certain cellars than in others. The first experiments in cultivating bacteria were in fluids, solutions of meat, beef tea, chicken soup, malt extracts, infusions of hay, etc., but fluids are open to the objection that they admit other germs, to coalesce with and rendered impure the special variety to be studied. Pure cultivation became possible only with the use of the pure culture soil, first employed by Koch. Germs falling upon a solid surface remain fixed in the same place. The solid culture soil made practicable the absolute isolation of germs, without which accurate investigation is impossible. Koch made his first studies with the common potato. The potato was the key to the whole subject of solid cultures. We might say that what the apple was to Newton the potato was to Koch. Subsequently gelatine was employed, then aqueous humor, then gelatinized meat preparations, peptonized gelatine, etc., and as a climax for the epicures, gelatinized blood. Thus has been determined the peculiar soil in which the varieties of pathogenic bacteria thrive the best. Thus while the bacillus of both forms of cholera develop upon both animal and vegetable soils (both being really exanthropic germs), the bacilli of tuberculosis will not grow in a vegetable soil as upon the surface of a potato, but will thrive in infusions of meat and luxuriate in the serum of the blood. The micrococcus of chicken cholera grows to swarms in neutralized chicken-soup, and the comma bacillus, which is really not a bacillus, but a form of vibrio or spirilla, develops in such luxuriance in alkaline meat soups as to have enabled Schottelius to detect it in minimum amount. In such cases, where but very few or doubtful specimens were present in the intestinal contents, Schottelius added to the contents two and a half times as much slightly alkalised infusions of meat, or ten times as much gelatinized meat peptones. In this mixture preserved uncovered in a warm place at a temperature not above 40° C. cholera germs developed in myriads within twelve hours.

Effect of Bacteria on Food.—In this connection a remark may be made upon the effect of bacteria upon the food selected, foreshadowing the local effects of micro organisms upon the tissues of the body in the so called local symptoms of disease. It is observed and distinctly tabulated if the gelatine or other food be fluidified, granulated, colored, decomposed, with or without the development of odors and gases, and the time required to induce these changes. Thus have the mycologists made us familiar with characteristic features of the vibrios of both forms of cholera, which fluidify gelatine, while the micrococci of pneumonia have no such effect; have pointed out the nail cultures of pneumonia, the air vesicles of Asiatic cholera, the flat scales of tuberculosis, the fern leaves of the micrococcus of erysipelas, the acacia leaves of one form of the micrococci of pus. So also of the effect of puncture or stick cultures show peculiarities different from plate cultures, and different effects are observed again with the same bacteria in different kinds of soil or food. Eisenberg has recently (Hamburg and Leipsic, 1886) published a Bacteriologische Diagnostik, which consists of a series of tables wherein are noted, in a form of inestimable value to the student of bacteriology, all these peculiarities of all known germs.

Concerning Temperature.—Three cardinal points are recognized of the temperature: the maximum, the minimum and the optimum. The optimum is the temperature most conducive to fructification, to spore formation. Excesses in either direction arrest certain processes, extremes destroy life. As might have been premised, non-parasitic enjoy much wider latitude than parasitic germs. Thus, according to Cohn, the bacterium termo grows between 5° and 40° C., with its optimum at 30° to 35° C., while the border temperatures of the bacillus tuberculosis, according to Koch, are 28° and 42°, with an optimum at 37°, the temperature of the human body. The conjoined influence of soil and temperature is shown in the conduct of certain bacilli (tyrothrix) found in cheese. The optimum temperature of this germ is 25° to 35° C. In a neutral fluid they are killed by a temperature of 90° to 95° C., while in a weak alkaline fluid they live at 100°. The mature spores of this species remain productive in a weak alkaline fluid after being boiled at a temperature of 115° C. Tyrothrix filiformis survives in milk a temperature up to 100° C., a degree fatal in one minute in an acid fluid. The spores of this species survive in milk a temperature of 120° C., while in gelatine they are destroyed at 110° C. This knowledge of the range of temperature gives a differentiation at once of parasitic from non-parasitic bacteria, as germs whose range is limited to 28° to 42° C., may not constantly find anywhere upon earth, outside of animal bodies, the necessary means of existence.

Need of Oxygen.—Such differences prevail regarding the need of oxygen that Pasteur separated all micro organisms into two classes, ærobes and anærobes. As, however, all known pathogenic micro-organisms must have oxygen more or less, the division is of more value to the mycologist than the clinician One point in this connection regarding the ammoniacal degeneration of urine is of interest to the practitioner

Bacteria of Urine —This degeneration, as is well known, results from the conversion of urea by the absorption of water, into the carbonate of ammonia, during which process the originally clear fluid becomes cloudy and opaque A drop of this urine under the microscope discloses myriads of germs of all descriptions Cohn has shown that one of them, the micro cocus ureæ, is the prime cause of the ammoniacal change Pasteur had already discovered that this micrococcus cultivated pure in a fluid containing urea induced in it the same change as in urine, and Musculus has since disclosed the fact that the change is induced by a chemical product, an enzyma separable by alcohol, excreted from this particular germ

The presence of oxygen is a necessary condition of the life of the micrococcus ureæ, which cannot, therefore, be the cause of the ammoniacal degeneration that in bad cases of catarrhal inflammation takes place within the bladder, a sac shut in from the outside air It was then assumed that this degeneration must be affected by other anærobic bacteria, and in fact, minute forms are found in freshly voided urine

It is interesting to know that Miquel discovered in dust a very delicate bacterium which vegetates in the absence of oxygen This bacillus he named the bacillus ureæ, because it has the power of converting urea into the carbonate of ammonia Hence the force of Teuffel's warning, "Put no soiled catheter into the bladder"

The Fecundity of Micro Organisms has been so often demonstrated in explanation of the suddenness of appearance of them in multitudes, and of the virulence of infectious disease, as to require mention here only for the purpose of checking the riots of the imagination It is known that a particle from a milzbrand bacillus, so small as to be invisible under an ordinary lens, introduced beneath the skin of a guinea pig, multiplies sufficiently to kill the animal in forty-eight hours, and a drop of the blood of the animal thus affected, properly inoculated, destroys the largest ox in a few days It is useless to dwell upon this point of propagation It was the recognition of it that more than another compelled the return to the germ theory of infectious disease when it seemed to have been routed even with contumely No purely chemical substance possesses this property The power of reproduction or self multiplication is limited to living things Chemical substance admit of great subdivision, as best exemplified, perhaps, in the dissemination of odors, but such subdivision is attended always with gradual loss of substance

Reproduction takes place in bacteria, whether by fission or spore formation, a rapidity bordering on the marvelous Cohn indulged himself in the pursuit of a calculation, reaching the conclusion that the progeny of a single bacterium, unchecked in growth, would in the course of three days reach the apalling weight of fifteen million pounds Troy, and in five days fill up a space of 928,000,000 cubic miles, the estimated capacity of the entire ocean But while some such calculations may be justifiable to convey some adequate idea of the degree to which the earth and the air may be filled in a few days during the prevalence of an epidemic, it must be remembered that it was flights of fancy like these that first brought the germ theory into discredit and derision Check is put upon the development and reproduction of all bacteria by the lack of nutrition, which sooner or later must ensue, as well as by the inimical action of different varieties upon each other Thus the bacteria of decomposition cease to multiply and perish by the myriad so soon as the material of their food is converted into inorganic matter, the bacteria of fermentation are destroyed, or their reproduction checked by the alcohol which they form, the bacteria of cholera with dessication, etc The bacteria of most diseases perish with the death of their host, as well as from various other causes in life, as by the fever they evoke, or are themselves destroyed by the bacteria of putrefaction

Thus it has been proposed to cure trachoma with the gonococci of gonorrhœa, lupus and epithelioma with the micrococci of erysipelas, and tuberculosis by the inhalation of the bacteria of putrefaction

Spore Formation —The conditions affecting the process of fructification are of extreme importance to the proper understanding of the cause and prevention of acute infectious disease A single bacterium is made up of several cells of parts, of which each cell forms one spore Pasteur first recognized these "brilliant corpuscles," but it remained for Koch to determine their significance, and for Prazmowski and Hueppe to establish their supreme value from the point of view of differential diagnosis The difference in the method of spore formation is also a chapter of itself which could find no discussion in the limits of this report It is enough to say here that characteristics of specific bacteria are as definitely determined in the observation of these phenomena as in the effects of inoculation Spores constitute the permanent forms

Endospores and Anthrospores —There is now quite general acceptance of de Bary's division of all bacteria into classes, one multiplying by endospores and one by arthrospores Endospores are spores evolved from protoplasm in the body of bacteria in such a way that the spore forms its own membrane, while an arthrospore is a transformation of an entire part or cell of a bacterium, the membrane of the bacterium forming the membrane of the spore True bacteria develop by endospores Such are the pathogenic bacteria, whether in the form of micrococci, as of erysipelas, pneumonia, gonorrhœa, suppuration, bacilli, as of tuberculosis, syphilis, leprosy diphtheria, milzbrand, glanders and typhoid fever

Spores are distinguished from micrococci by their bluish, opalescent cast, their high refractive power, and their obstinacy to color, because of the impermeability of their membranes Strong acids and extreme heat, which kill the protoplasm of the bacteria, injure the vitality of the spore membrane, to make it permeable and admit color Under such conditions spores may be colored intensely while the body of the bacterium is only feebly or not at all affected by color Spores of all kinds are characterized by extreme tenacity of life Most endogenous spores remain productive after exposure to 100° C, many even to 130° C Anthrax spores survive a dry heat of 123° C Endospores survive dessication on an average about one year, those of the bacillus subtilis, according to Brefeld, three years Pasteur claimed to have kept spores in hermetically sealed tubes, capable of reproduction after twenty-two years Such long sustentation of life is capable, of course, only under favoring conditions Botanists generally admit persistence of vitality in seeds from ten to twelve years Statements of persistence for centuries, as from mummies' tombs, are considered mythical As a rule, as stated, spores perish in a few years, so that limit is to be put upon the assertion of an enthusiast in antisepsis that ' time does not destroy septic dirt "

Bacteria of the Alimentary Canal—The surface of the earth is the bottom of an ocean of air teeming with micro organisms of every description The origin, character and distribution of these germs is a subject of itself Myriads of them, among others, pathogenic germs are ingested and inhaled every day The alimentary canal throughout its length is described as a rich garden of vegetating bacteria Most mature forms ars destroyed in the stomach under the action of the gastric juice, but many spores, and some mature forms—sarcinæ for instance—escape to reach the intestine with all the favoring conditions of a hothouse The mycologists speak of the flora of the feces, in fact, masses of feces are almost wholly masses of bacteria

Bienstock, who has made a special study of these bacteria, succeeded in isolating one bacillus endowed with the specific property of decomposing albumen and fibrin Cultivated to obtain sufficient quantity it separates albumen and fibrin through all the successive stages of decomposition with its gases down to its final products, carbonic acid gas, water and ammonia No other bacteria have this property Artificial albumen is not attacked, and casein is not touched by it Hence it is that the stools of sucklings emit no fecal odor

These bacteria of the intestinal canal belong to the class of *saprophytes* They have to do with the resolution of organic into inorganic matter, and they are hence the greatest friends of man They have no power of penetration to the blood It is now almost universally conceded that no germs exist in the physiological interior of the healthy body No germs exist in healthy blood An apparent exception proves the rule In a number of observations with negative results, Klebs once found bacteria in the blood of an apparently healthy dog It was subsequently learned that bacteria of decomposition had been previously introduced into this dog in an experiment on wound sepsis The animal had long since perfectly recovered The germs found by Klebs had still survived, and were remaining at the time of the *observation quiescent* It was an observation useful also in illustration of the latent stage of disease But even useful saprophytic germs become dangerous when they do enter the blood through breaks, sloughs or ulcers formed by pathogenic germs Such secondary saphrophytic immigration occurs in diphtheria, typhoid fever and small pox as to have until recently occasioned much confusion in the recognition of the true pathogenic germs Invasions of this kind, independently of these diseases, are probably responsible for many non-infectious septicæmias of surgery and obstetrics, as well as for many vague "rheumatisms," malarias," "colds," "teethings," and "gastric fevers" of internal medicine

Pathogenic micro organisms enter the blood through solutions of continuity in the surface of the skin and mucous membrane, including the lungs The germs of tuberculosis, pneumonia and all the acute exanthemata probably enter the blood by way of the lungs, which permit the passage of larger and grosser matters in the dust of coal, iron, etc Each micro organism has its own history in its preference of site, *mode of invasion, dissemination* and effect upon the tissues of the body A notice of one or two of the best studied will serve in illustration

The micrococci of erysipelas are deposited upon the epidermis at some break of the surface, which break may have entirely healed by the time the disease is recognized, to distribute themselves chiefly in the lymph vessels of the skin and subcutaneous fat Hence the superficial character of the disease They multiply, according to Fehleisen, in a direction opposite to that of the lymph currents They are never found in the blood or in distant organs

The bacteria of decomposition take quite a different course One set, the staphylococci, multiply in the connective tissue without entering the lymph vessels, another set, the streptococci, enter the lymph vessels and follow their course to constitute the lymph—angiectatic processes Suppurative phlegmonous tracts indicate their presence

The micrococci of gonorrhœa are endowed with the property, according to Bumm, of penetrating to and multiplying in the protoplasm of the urethral cells to effect their dissolution Hence they are distributed by the lymph vessels or are carried directly, to be found in the bladder, kidneys, Bartholine glands, periurethral abscesses, rectum, neck and body of the uterus, sacs of the conjunctivæ, and *joints of the knee*

The bacillus tuberculosis, which is at the present time perhaps the most universally distributed of all pathogenic germs, finds less ready victims than that of cholera and milzbrand, because of its immobility, its slower growth and less poisonous products On account of these factors the extension of the disease in the body remains, as a rule, circumscribed Wandering cells sometimes carry it, but its transfer to distant organs, bones, joints, testes, meninges of the brain, etc, is chiefly effected by a quite accidental irruption into blood and lymph vessels Thus, Weigert has demonstrated at local depots the erosion of and penetration into the walls of veins, Koch a direct irruption into small arteries, and Ponfick the perforation of the thoracic duct with the sudden inundation of the whole body to constitute the clinical picture of miliary tuberculosis Thus, also, is easily explained the sudden aggravation of tuberculosis in latent, quiescent and convalescent cases of the disease

Eberth and Gaffky likewise describe the penetration by typhoid bacilli of the intestinal mucous membrane, with subsequent infiltration of the submucous tissue, muscular coat, mesenteric glands, and escape thence into the blood to accumulate in the spleen Hein claims to have discovered them in the spleen during life, but Frænkel and Simmonds (*Die ætiologische Bedeutung des Typhus Bacillus*, Hamburg and Leipsic, 1866), with good reason discredit this claim, though they were able to make pure flat cultures from the spleen post-mortem in twenty-five of twenty-nine cases The bacilli of typhoid fever increase in the spleen so rapidly soon after death as to render their detection easy

The Effect upon the Tissues of the body presents the same differences as the effect upon culture soils outside of the body, and here again each micro organism shows its own peculiarities The superficial catarrhal and diphtheritic processes, parenchymatous infiltrations, coagulation necroses, neoplasms, etc, coarsely correspond to the alterations observed in the artificial culture soils

Erysipelas, again, a surface disease, open to inspection, offers in the studies of Fehleisen perhaps the most accurately recorded observations in this regard Fehleisen found that he could distinguish four layers or zones of inflammation The first, the peripheric, extended about one centimetre beyond the reddened and elevated border wall It showed no visible lesion, either in color or thickness, though its lymph vessels were stuffed with micrococci The wall mentioned is itself the second zone, the zone of inflammatory reaction It consists of the rapidly multiplying micrococci with wandering cells which have partly taken up, included or ingested the bacteria, to finally displace and substitute them altogether A small celled infiltration with a total absence of bacteria marks the third zone, while the fourth shows only pallor or anæmia of the skin in process of restitution *ad integrum* The accompanying fever and gastric catarrh—out of all proportion at times to the extent of the disease—are the results of chemical changes induced by the micrococci

The fact that the same local phenomena are present in erysipelas migrans without constitutional signs, would indicate that this disease is due to a different, though allied germ Rosenbach found this disease often in individuals whose avocation deals with animal matter Slight wounds of the hands in butchers, tanners, cooks, are frequently points of origin for a brownish red infiltration which takes the precise course of erysipelas From this infiltration he was able to cultivate a special micrococcus inoculable by puncture, to produce the same condition

True erysipelas is entirely unattended with suppuration or other destructive change than fatty degeneration of the epithelial cells and restitution by new formation Suppurative or phlegmonous processes indicate a mixed infection with the staphylococcus or streptococcus which produce this condition The supervention of a still graver complication, gangrenous emphysema, is due to another micro organism, this time a bacillus, of entirely different nature, whose effect is to produce hæmorrhagic infiltration of the deeper muscular structure, with the development of the gases of decomposition

Action of Micro Organisms on an Internal Surface —A good illustration of the action of micro organisms on an internal surface soil is offered by Loffler in the growth of the dumb bell bacillus of diphtheria, which produces deep and extensive layers of false membrane in the fauces, pharynx, and trachea The glutinous and pultaceous mass thus formed is a quicksand to catch and entangle the myriads of micro-organisms ingested and inhaled, in such inextricable confusion as to have made it for a long time impossible to pick out the specific cause of the disease Beneath this superficial layer Klebs and Loffler at last succeeded in finding a special layer containing numerous cells among which, aggregated in small colonies, were special bacilli which admitted intense coloration with methyline blue The layer beneath this again, directly superimposed upon the dilated vessels, is a fibrinous mass composing the bulk of the false membrane It contains but few cells and no bacteria, and represents the product of reaction of the mucous membrane to the virus of the bacteria This deepest layer is produced by the coagulation of a fibrogenous exudation which escapes from the blood-vessels and opposes a barrier to the further advance of the bacilli Breaks in this barrier permit the absorption of the virus emanating from the bacteria or their products, to produce the constitutional symptoms of the disease

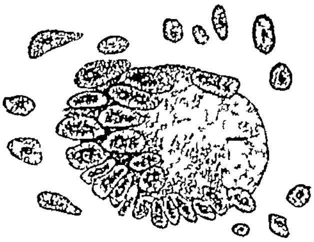
Production of Neoplasms by Bacilli —The bacilli of tubercle, leprosy, syphilis and glanders affect the soil of their selection in the body quite differently, in that they produce granulation tumors, neoplasms characterized by a tendency to rapid dissolution by fatty or calcareous degeneration The cellular element of these tumors resembles that of the lymph glands Taking tubercle as a sample, they are round cells, of various size, the medium size resembling a white blood corpuscle, with small, round, shining nuclei, provided with nucleoli The large cells contain two, even up to twelve nuclei Accumulation of these cells constitutes the nodule which the old anatomists named tubercles

A tuberculous mass, on schematic section, shows an outside ring of round cells provided with a single nucleus about a narrow ring of epithelioid cells, which finally enclose one or more giant cells The bacilli of tuberculosis are found in all parts of the tuberculous mass, free—that is, between the cells—as well as in the interior of the cells

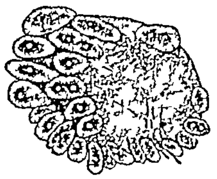
Behavior of Bacilli in Giant Cells —But the most characteristic as well as curious phenomena are presented in the behavior of the bacillus in giant cells, a question which brings the subject to its most intimate ultimate relations

The giant cell, as is well known, is distinguished by the number of its nuclei, as well as by its size When now but a single bacillus penetrates to the interior of a giant cell, whose nuclei are disposed about the circumference of the cell, it is commonly found in the free space at or near the middle of the cell But it is more common to find all the nuclei grouped together at one end, with the bacillus at the opposite, often at the extreme opposite, end of the cell The poles of the cell are thus occupied, one by the nuclei, the other by the bacillus Thus they stand facing each other like foes, and it is impossible to resist the conclusion that there exists between them an antagonism which keeps them as far as possible apart

When two bacilli are present it is not unusual to find one at each end or pole of the cell, while the nuclei are all grouped about the centre or equator, or the relations being changed, the bacilli are disposed at the equator while the nuclei are grouped at the poles It looks, Mittenzweig says, as if each group of nuclei was holding a bacillus in check When the number of bacilli is greater, they do not long remain in this passive state For they are soon to be seen at different places in the cell, close to and between the nuclei, with their long axes perpendicular to the surface of the cell The wall of the nucleus is thus broken down and the giant cell succumbs Groups of bacilli are thus found arranged in stellate form, but no longer surrounded with nuclei

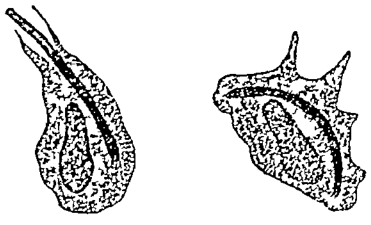


The Bacillus in the Giant Cell



Koch concludes, hence, that the penetration of an epithelioid cell by one or more bacilli is the *first step* or stage in the origin of a tubercle The virus or poison emanating from the bacillus irritates the cell to such degree as to lead to increase in its size and multiplication of its nuclei, in other words, directly to produce the giant cell The irritation extends to neighboring cells, to induce hyperplasia, and to vessels, to lead to emigration of the white blood corpuscles Meantime, the struggle continues in the giant cell, to end occasionally in the destruction of the bacillus, but far more frequently in the triumph of the germ They then break through the circle of nuclei, *escape from the wall of the cell to attack new* cells with similar fate The ruptured cell suffers necrosis, the plasma current ceases, plasma and nuclei coagulate, nuclei are broken up into debris, and the whole cell is converted into a homogeneous, inert, dead mass The condition may be arrested at this stage, as in the spleen, or may, as is usual elsewhere, suffer a later conversion into caseous matter Bacilli which have not escaped to other cells perish with the death of the cells, their hosts Syphilitic neoplasms show the same phenomena, except that they are more prone to undergo fatty degeneration, resorption and cicatrization (Mittenzweig)

Bacteria in the Blood current —The conduct of bacteria in the blood current itself or their effect or action upon the elements of the blood is but little known In most cases the stay is too short for any permanent effect But one curious observation has been made by Metschnikoff concerning the bacilli of milzbrand and the white blood corpuscles, which throws light upon the question of susceptibility and immunity of disease With suspicion based upon the familiar fact of the absorption of food and foreign bodies into the interior of amœboid bodies, by protoplasmic protrusions and inclusions, and more especially upon the observation of a disease in small crustacea caused by the entrance or ingestion of a peculiar sprosspilz into the coloring blood corpuscles of the animal, Metschnikoff concluded to study the relations of the milzbrand bacillus to the white blood corpuscles of vertebrate animals He soon discovered that the blood corpuscles of susceptible animals (rodents) only exceptionally incorporated virulent bacilli, *whereas the blood corpuscles of insusceptible* animals (frogs, lizards) took them up abundantly Being thus ingested or included they soon perish in the interior of the cell, to finally entirely disappear The same fate awaits milzbrand bacilli in the bodies of susceptible animals, when the virulence has been attenuated or abstracted in any way, as by artificial heat



Leucocytes as Phagocytes

Immunity —These observations, should they meet with wider confirmation, must throw light upon the obscure subject of immunity conferred by an attack of disease against its repetition, as well as upon protective vaccination For we lack as yet a sufficient or satisfactory explanation of the immunity thus conferred, though three plausible hypotheses have been proposed The first is the theory of exhaustion, which assumes that the germs of the disease exhaust the elements in the blood necessary to their nutrition Something analogous to this is seen in vegetation of higher structure, which cannot be made to grow indefinitely in the same soil The second is the antidote theory, or the theory of antagonism, which supposes that certain products evolved from the soil in the multiplication or growth of germs react upon them fatally The analogy here is found in the process of fermentation, whereby the torulæ cease to produce themselves, *become quiescent and sink to* the bottom of the vessel as soon as the proportion of alcohol reaches twenty per cent There is reason to think that the fever evoked by micro organisms is in some cases fatal to their growth and life. The third is the theory of accommodation, which maintains that the tissues in their first struggle with the micro-organisms acquire a higher degree of energy or vitality, whereby they are enabled to endure or resist future attacks. Perhaps a simile may be found for this hypothesis in the process known as acclimatization.

Incorporation and Absorption of Germs.—The observations regarding the incorporation and absorption of non-virulent or less virulent germs tend to support the theory of accommodation. For it would follow from them that protective vaccination, or more properly inoculation of weak bacteria, must confer upon the blood corpuscles the power to incorporate and destroy virulent bacteria. When protection is not sufficiently secured at once by a certain grade of attenuation, it might be accomplished by successive attempts with gradually increasing potencies. Thus successive inoculations of gradually increasing virulence would finally permit the introduction into the body of the most intensely virulent bacteria with impunity. It is upon this theory that Pasteur bases his claim to secure prophylaxis in hydrophobia, a disease in which sufficient time lapses, as a rule, between the wound and the symptoms to make experiments even after the wound, in the hope of anticipating the attack of the disease. The fact that virulent bacteria are not absorbed would indicate, in the absence of any morphological difference, the presence in these bacteria of some chemical substance which antagonizes the cell. Moreover, the character of the constitutional symptoms; sopor, stupor, coma, delirium, which supervene in cases of grave acute infections, speak in favor of this view, and against the belief that bacteria act mechanically or by the abstraction of oxygen. In fact, neither the local nor the general signs of infectious disease are ever produced or can be produced in this way.

How do Micro-organisms Produce Disease?—The question now arises, how do pathogenic micro-organisms produce the phenomena of disease? From the rapidity of their multiplication, it might be inferred that the symptoms and lesions of the infectious maladies were caused by the mere presence of these organisms as foreign bodies. But it has been observed that the bacilli of milzbrand alone multiply in the body in such number as to produce extensive occlusions of vessels. Further, it has been shown that no mere mechanical presence, no mere foreign bodies, aniline particles, or granules of cinnabar, ever induce the signs of fever or toxicemia. The micro-organisms of disease live in the body, and must therefore be nourished at its expense, whereby they withdraw from the blood or tissues elements essential for their nutrition. Pathogenic micro-organisms require oxygen. In processes of fermentation outside air is excluded, that the germs of fermentation may be compelled to withdraw oxygen from its soil. Pathogenic micro-organisms multiplying in great abundance seize upon the oxygen of the blood with such avidity as to develop in fulminant forms the symptoms simulated by prussic acid poisoning. But the the other symptoms mentioned do not correspond either to deficient oxygenation or carbonic acid poisoning.

These symptoms indicate toxicæmia, and since the injections of fluids from which bacteria have been separated by porcelain filters remains innocuous, it follows that the toxic agent inheres with the bacteria. Then, inasmuch as blood corpuscles show their reaction against bacteria on simple contact, it follows that the poison must lie upon or issue from their surface.

Ptomaines.—The only hitherto known poisons which may in such minute quantities induce such grave toxic signs are the poisons resulting from the action of the bacteria of decomposition upon organic matter. As these intensely virulent poisons were first observed only in dead organic matter, they were called ptomaines (from πτῶμα, the fallen, a corpse, hence more grammatically ptomatins). These matters, the ptomaines, though so newly known, have received so much attention in the past year as to form a subject in themselves. It may be said here that some cadavers develop no ptomaines, that ptomaines are developed as putrefaction advances in the course of weeks, next that they are also found sometimes in animal products, as in cheese, urine, fæces, etc., and lastly, that many ptomaines are perfectly innocent. Then it might be added that many phenomena attributed to their action have been found due to simpler causes. Thus the claim of Passet that any one of the eight forms of bacteria which he cultivated from pus would coagulate sterilized milk were found to rest upon simple lactic acid fermentation.

Brieger, who has made the most exact observations, operated with the Koch-Eberth bacillus of typhoid fever, which he cultivated from the spleens of fatal cases, and found to be identical with the pure cultures in the laboratory of Koch. These bacilli thrive in solutions of sterilized grape sugar, to which have been added the proper nutritious salts. This clear fluid, kept in sealed tubes at a temperature of 30° C., becomes opaque in twenty-four hours after introducing the bacilli, and emits, on opening the tubes, a distinct odor of ethyl alcohol, which increases from day to day. Besides the ethyl alcohol, there develop small quantities of volatile fatty acids, together with acetic acid in large quantity. The typhoid bacillus has also the property of inducing in solutions of grape sugar the lactic acid fermentation. Sterilized bouillon or minced meat used as soils, soon become alkaline, but develop, even after the lapse of eight weeks, none of the products or gases of decomposition. From these as from all albuminous cultures, Breiger was frequently but not always able to obtain a basic product which gave the chemical and physiological reactions of a ptomaine. In guinea-pigs it produced a slight ptyalism and an increased rapidity of respiration, to be followed later by a loss of power in the muscles of the extremities and trunk, without a distinct paralysis. There is diarrhœa throughout, death takes place in twenty-four to forty-eight hours. The same observer is now experimenting with the septic diseases whose abnormal temperature elevations, interruption of functions, benumb ing of the intellect, perverse action of the digestive apparatus indicate abnormal chemical changes in high degree

Nicati and Reitsch, Villiers, Pouchet, have all made similar investigations with the bacteria of cholera According to Pouchet, chloroform extracts of cholera dejections furnish an easily oxydisable and intensely poisonous oily substance which is certainly a ptomaine Mere traces of it introduced into the bodies of frogs induce retardation of the pulse, with speedy death attended by muscular rigidity

Villiers also succeeded by the method of Stas in isolating a ptomaine from the intestines, kidneys, liver and blood in two cases which had succumbed to cholera It was abundant in the intestines, but very scant in the blood It had a sharp taste and an odor like the flowers of the white thorn It had no effect upon frogs, but caused in guinea pigs retardation of the pulse, *tremor and death*

According to the same author cultures of the cholera bacteria have a peculiar ethereal odor which is not unpleasant Solutions of this culture not over eight days old in bouillon or gelatine filtered free of bacteria, injected into the blood of dogs induces diarrhœa and great depression, with dyspnœa, disturbances of motion and sometimes death

These experiments are cited merely as samples to show the direction of research at the hands of the most advanced observers in the past year They indicate the lines of study by means of which we shall be able to combat the cause of infectious disease in a direct way They show us that the time is at hand when, as Brieger observes, we may as practitioners of medicine no longer be compelled to rely upon a raw empiricism, when we may find a specific therapy, if not remedy for a specific cause, since we have already learned that the accumulation of certain products of bacteria kill them They show us *that inflammation is not the cause but the effect of* disease which is caused by infection They show us the direct road to cure through comprehension of the nature of infection

SUGGESTIONS ON THE PURITY OF CHICAGO DRINKING WATER[1]

BY H GRADLE, M D

EYE AND EAR SURGEON TO MICHAEL REESE HOSPITAL

No question of local sanitation has been more often and less intelligently discussed in Chicago, than the purity of our drinking water While alarmists have filled the newspapers with sensational exaggerations, our authorities have denied all danger on grounds insufficient to prove the point

The starting point of any discussion must, of course, be the fact, that the sewerage of this enormous city is carried into the lake—the source of our drinking water, whenever the current of the river runs towards the lake, which occurs a large part of the time Now, as there is no direct evidence that any one disease or class of diseases are due solely to the drinking water thus contaminated, how can we decide whether any danger to health lurks in this water? Chemical examination can only tell us whether organic material exists to a larger extent in our drinking water than it does in other parts of the lake remote from our shore, or than it did in the same waters many years ago

But a positive result of such analysis would not necessarily condemn the water unless there were an excess of albuminoid ammonia larger than the limit shown by experience to be safe in drinking water

On the other hand, when the analysis shows no marked change in the quantity of organic constituents in the water, it does not decide the question as to the safety of the water For there is no reason to think that in our present case, where the sewerage is diluted by the enormous body of water in the lake, there can be enough of any chemical substance present to produce any poisonous effects A chronic poisoning or a cumulative effect produced by the continued ingestion of an *organic* poison in such small quantities as not to produce any immediate sensible action is not known, and such a possibility is a gratuitous assumption not based on clinical evidence We are forced, therefore, to look for living micro organisms in any suspicious water—for at the present no other *direct* causes of diseases are known

The algæ and diatoms, and occasional infusoria, figured by amateur scientists in the newspapers as existing in our drinking water, are about as harmless as any other vegetable or animal tissues we might eat as food It has never been shown that they are really poisonous or parasitic to the body The micro organisms which demand our attention as suspicious, are the bacteria Since they are not numerous in any but stagnant water, the direct examination of the water with the microscope teaches very little Besides, hardly any variety likely to exist in the water could be identified on finding a specimen or two with the microscope

In order to tell what there is in the water, we must do exactly as if we had a few seeds mixed with a lot of sand, and were unable to recognize them We would sow them over a large surface of ground free from other plants and wait for the result,—identifying the plants as they grew up

I have made a few such analyses of our lake water, according to the methods devised by Koch The sample bottles with flat sides which I show you here, are thoroughly cleansed and boiled, and then partly filled with a small quantity of nutrient gelatine and their mouths plugged with cotton The bottles and their contents are then sterilized by heating them in a steam bath for a few minutes on several successive days This being properly done, they will keep forever without the occurrence of any bacterial growth in them If now one or more drops of water flowing from the faucet or received in a sterilized beaker are dropped into these culture bottles while momentarily lifting the cotton plug, any bacteria or their spores thus introduced with the water will grow *in the gelatine* If the drops of water are thoroughly mixed by shaking with the gelatine liquefied by gentle warming, the germs will be separated from each other, and on letting the mixture suddenly congeal on the large surface of the flat side of the flask, and keeping the flask at a temperature of 18 to 22° C., the number of colonies of bacteria growing in the gelatine will indicate the number of germs contained in the water. Within 36 to 72 hours according to the temperature, the colonies grow sufficiently large to be counted with the naked eye.

---

[1] Read before the Chicago Medical Society, May 3 1886

In order to identify the species we must note the appearances and size of each colony, and then examine with the microscope the cells composing such a colony, both in the fresh state and after staining. If this be insufficient to recognize the variety, we must make fresh cultures from such a colony in other and different cultivating media, or finally test for pathogenic properties by experimentation on living animals.

There is, however, a limit to the capability of this method, viz. our want of familiarity with all the pathogenic species of bacteria. Apart from cholera we know only one disease which has been traced in some instances to impure drinking water, and of which we can identify the causative parasite, viz. typhoid fever. It is very likely that there are other intestinal disorders of parasitic origin—the different forms of enteritis and dysentery, the germs of which may be at times introduced by means of impure drinking water. But this could not be proven at present, because we do not know as yet the presumable germs of these diseases. It is also not impossible that the bacilli of tuberculosis, or their spores, may sometimes enter the system through the alimentary canal. Whether any other but intestinal affections can be started by entrance of their causative parasites through the digestive tract, is not known in the case of any diseases of man, but judging from the mode of introduction in animal anthrax, which is most frequently intestinal, this is not an improbable occurrence.

In the culture analysis which I have made, I have counted from 35 to about 50 germs per drop of our hydrant water—equivalent to about 1000 to 1500 germs per cubic centimetre. This is much more than Frankland found in London drinking water (from 8 to 70—extreme 382), and more also than was obtained by the German Board of Health from the Berlin water (usually from 20 to 100 or 200—sometimes to 400, exceptionally), though the latter contained as much as 1000 germs in each centimetre, before filtration in the water works. However, as bacteria exist in all fresh waters on the surface of the earth, there is nothing in this indicating any special impurity, for as we can judge from every day experience, the immense majority of these bacteria are harmless. In my earliest observations, last summer, I counted six different varieties in my flasks. Since then my time and facilities did not permit me to continue the very tedious microscopic research necessary for differentiating the colonies. But from the gross appearances of the colonies with which the first observations made me familiar, I would say that only three or four kinds of bacilli are common, while other kinds of bacilli and occasional micrococci and spirilla are less frequently found. Many, if not most of the micro-organisms in our hydrant water exist in the form of spores, which are not killed by momentary boiling. On staining the residue of a few drops of water evaporated on a slide, there are indeed very few developed forms found. I need hardly add that I have not identified any pathogenic varieties.

Although these few analyses would, therefore, not entitle me to say that our water contains any deleterious matter, I do not see how we can escape the conclusion that there is really danger, however slight, in the use of our lake water. There were last year about 500 deaths from typhoid fever in this city. This means, perhaps, 5,000 to 6,000 cases of that disease. The discharges of all these patients contained typhoid bacilli, which were carried into the lake. Though the bacilli may die speedily in the water, their spores persist for days, if not for weeks and months. Is it at all conceivable that the currents should not carry at least some of them at times into the crib and water-pipes? I will not insist on the possibility of the discharges of different forms of diarrhœa and dysentery reaching us in a diluted form in the drinking water, because, as I said before, we are not yet familiar with the germs of these diseases, and do not know whether they produce persisting spores. Indeed, outside of typhoid fever, I could not name any danger threatening us in the water, if I depended *only on the known facts*, but analogies and probabilities suggest a great deal more. The enormous dilution to which the sewerage is subjected when carried into the lake, reduces, of course, the probability of infection through drinking water very much, but does not remove it. The self-purification of water, which undoubtedly occurs through the starvation of the micro-organisms, and their deposition, and perhaps oxygenation, pertains principally to the developed forms and not nearly so much to the spores. In short, we cannot but reason that of the millions of disease germs poured into the lake, some few must find their way back into the systems of some of those who drink it.

Of all the purifying processes of drinking water, boiling is the simplest. About twenty minutes vigorous boiling deprives the water completely of all living germs. But the flatness of boiled water, as well as the turbidity which the Chicago water commonly presents, renders filtration desirable. Frankland has found that sand or coke, or spongy iron, in layers of about six inches thickness, remove nearly, if not all micro-organisms from the water filtering through them, but that this retaining power decreases steadily in the course of weeks. As far as I have learned, most of the filters here in the market contain sand or charcoal, and as I have been told by parties using them, many do not furnish water as clear after some weeks or months as they do at first. The layer of filtering material is neither thick enough nor sufficiently packed to retain all bacteria, and should besides be changed from time to time. One charcoal filter which I tested gave a clear water, containing, however, nearly as many germs as the original hydrant water.

A filter on a different plan, and which I have examined more minutely, is the Mallie Aerifilter (French patent), similar to the one devised by Pasteur's assistant, Chamberland. It consists of a cylinder, with conical end, made of unglazed white clay, screwed water-tight to the faucet, and surrounded by a protective glass cap. If there be sufficient pressure in the pipes, the water filters through this clay cylinder drop by drop, to the extent of some two to four gallons per day (in Chicago). All visible solid particles are left in the interior of the cylinder, in the form of a slimy coat, which should be washed out once in two to four weeks. The muddy washings from this cylinder gives one a rather exaggerated idea of the dirt we are forced to drink. The microscope shows it to consist of about half of living bacteria and brilliant particles (presumably spores), the other half being clay and sand, with occasional vegetable cells and fragments. The water furnished by this filter is of remarkable transparency. The very residue in the filter shows that very few bacteria can have passed through into the water, but I cannot say that it is absolutely perfect, as would appear from a testimonial given this filter in the Municipal Laboratory at Paris. On testing the water, by allowing drops to fall from the filter into gelatine flasks, I have found that when the filter was well cleansed within some hours the water was entirely free from micro-organisms — but when the filter was left undisturbed for days and weeks, a few colonies were invariably obtained, usually less than one-tenth the number contained in the original water. There were, moreover, not so many varieties as in hydrant water —generally but one or two. I have some reason to think that most of these bacteria found in the filtered water did not pass through the filter, but that the very few germs which did pass through, or which possibly came from the air, multiplied to some extent in the film of water between the clay cylinder and the surrounding glass, for it is well known that even distilled water allowed to stand for hours harbors numerous bacteria. I judge so from the fact that after cleaning the surface of the clay cylinder with a sterilized brush and with water previously boiled, and readjusting the glass cap after purification by boiling water, the filtrate was usually free from micro organisms for several hours. This multiplication of bacteria on the surface of the filter does not detract from its merits, because in a film of water containing as little organic matter as ours, no bacteria of parasitic habitat, and hence, at all dangerous, could multiply.

MEDICAL PROGRESS

THE ACTION OF UNNA'S PLASTER-MULLS.—In his observations (*Deutsche medicinische Wochenschrift*, December 17, 1885) L. HOFFMAN refers especially to the gutta percha plasters. These have advantages over the salve muslins (Salbenmulle), they are permanent, adhesive, comfortable, cleanly, and are more active.

The boric acid plaster proved of value in leg ulcers. A new plaster, large enough to cover the hardened border of the ulcer, was applied daily, later, after the surrounding parts had become somewhat softened, it was applied to the ulcer only. The ulcer became gradually smaller, the last part being healed by a weak nitrate of silver ointment. Four cases are given, in all of which the result was favorable. In the treatment of bedsores this plaster also acted admirably.

Chrysarobin plaster (18 per cent. strength) gave excellent results in psoriasis. In its use there was no danger of the chrysarobin-conjunctivitis, and the erythema produced by the drug did not extend beyond the parts covered by the plaster.

In several cases of eczema in which the disease was dry and circumscribed, oxide of zinc plaster was employed and effected rapid cures. In the more severe forms the zinc and tar plaster was found efficacious. In obstinate cases naphthol plaster (10 per cent. strength) was tried with satisfactory effects. This last plaster proved useful also in a case of beginning lichen ruber.

Salicylic acid plasters are recommended for the treatment of infiltrated patches of eczema, also in verrucous and sclerous patches. This plaster also acts well in epidermal hypertrophies, as clavus and callositas. In clavus salicylic acid and mercury plaster is preferred on account of its being less painful. Salicylic acid plasters were found of value in the vegetable parasitic diseases, also in lupus and acne rosacea. The pain that the stronger salicylic acid plasters sooner or later give rise to, may be moderated by the use of those containing 15 per cent. of extract of cannabis indica.

The mercury and carbolic acid plaster gave good results in furuncles. It acts differently according to the stage of the lesion. If applied in the beginning, the furuncle is aborted, if suppuration has set in, the same continues, but the process is painless. The frequency of renewal of fresh plaster depends upon the amount of suppuration. This plaster acts equally well in other phlegmonous inflammations.—*American Journal of the Medical Sciences*, April, 1886.

COCAINE IN CIRCUMCISION.—DR. JOHN MADDEN, of Wisconsin records a case in which he used a 4 per cent. solution of muriate of cocaine in circumcision.

Four points, practically equidistant, were selected upon the line of the intended incision, the hypodermic needle inserted, and about one fourth of a drachm of the solution was injected beneath the skin at each of these points. A piece of absorbent cotton was then saturated with the fluid, and placed in contact with the preputial mucous membrane. Testing the sensibility of the parts from time to time, by pricking with a needle, in about twenty minutes the sense of feeling was almost entirely abolished. The foreskin was then drawn forward, held between the blades of a pair of dressing forceps, and quickly ablated with a knife. The patient declared that the operation gave him no pain nor sensation of any kind, except ing in one small place on the left side. I noticed, however, that the solution had filled the subcutaneous tissue beneath this place. The mucous membrane was next caught up, and quickly cut off with a pair of scissors. Its sensibility, though very much lessened, was not entirely destroyed, and the patient complained of some pain. The operation was completed by stitching the mucous membrane and integument together, the former growing more painful towards the end of the operation, while the latter preserved its anæsthesia.—*Therapeutic Gazette*, April 15, 1886.

THE SUGAR-FORMING FUNCTION OF THE LIVER.—In response to Hofmeister's recent adverse criticism (*Archiv f. exp. Path. und Pharm.*, xix.) of the view that sugar was formed in the liver out of peptone, PROF. SEEGEN, of Vienna, gives the details of some experiments in which he found that the quantity of nitrogen yielded from 100 c.c. of fresh arterial blood mixed with fresh liver tissue, and treated with a current of air for some hours, was greater when a small quantity of peptone had been added. The quantities of nitrogen in six experiments were:

WITHOUT PEPTONE	WITH PEPTONE
0.113	0.300
0.050	0.105
0.043	0.092
0.114	0.252
0.140	0.216
0.070	0.159

The peptone and other proteids having been completely removed before the nitrogen was estimated, it must have come from the products of decomposition of nitrogenous materials and it appeared doubtless to him that in the presence of arterialized blood the liver cells split peptone into sugar and some crystalline nitrogenous product, and he believes that at least in the case of carnivorous animals, one of the chief duties of the peptone is to form sugar.

In a second paper Prof. Seegen gives three experiments on dogs by which he attempted to settle finally the vexed question whether a diet of cane sugar causes sugar to appear in the urine. He found both cane and inverted sugar in the urine in all three experiments.

In a third paper he brings forward elaborate arguments to prove that the production of sugar in the liver is not—in contradistinction to the production of glycogen—interrupted by inanition or increased by abundant carbohydrate ingesta, but is an independent and unintermittent function of the tissue changes.—*Archiv f. d. Gesam. Physiologie*, Bd. xxxvii, November 5, 1885.—*American Journal of the Medical Sciences*, April, 1886.

EMBOLISM OF THE AORTA.—DR. VINCENZO CAMMARERI, of Naples, has published a memoir upon Obliteration of the Abdominal Aorta, which is summarised in *Le Progrès Médical* (No. 13). He has collected all the cases on record, starting from Barth's case in 1835 and Romberg's ten years later. In the majority the cause is embolism proceeding from the ventricle, the embolus being arrested at the bifurcation of the aorta, and leading to secondary thrombosis extending upwards—rarely above the level of the renal arteries—and downwards into the iliac arteries and their branches. The event is marked by the sudden appearance of complete and painful paraplegia. The sphincters are generally unaffected. Sometimes there is tetanic rigidity of the lower limbs; the reflexes and sensibility are abolished. Often in addition there are other symptoms—as hæmaturia, ischuria, suppression of urine, rachialgia, acute decubitus, etc. Whether a fatal result occurs rapidly or not depends upon the extent to which the vessel is obliterated; in some cases, owing to partial obstruction or to a certain amount of collateral circulation, life has been prolonged for several weeks, or even months. The paraplegic symptoms have been ascribed by some to anæmia of the muscles, by others to anæmia of the cord; but the writer demurs to the latter explanation, except in cases where the coagulation has extended high enough to block the lumbar arteries; but even here he thinks the paralysis may be explained by interference with the muscular nutrition. Experimental ligature of the lumbar arteries in the dog produces paresis of the hind limbs, but the paraplegia equally follows the infliction of the wound without ligature. The author then explains the muscular paralysis following upon obstruction of the aorta as being due to the absence of oxygen and the presence of an excess of carbonic acid in the tissues. In like manner he explains the absence of reflexes; whilst the occurrence of muscular rigidity in some cases is compared with cadaveric rigidity—attributable, that is, to coagulation of myosin, and not to over-excitability of the muscle. The same "asphyxial" condition of the tissues is held to account for the anæsthesia, whilst the symptoms of pain is attributed to irritation of nerve fibres from the presence of products of disintegration, the nerves being rendered excitable by imperfect anæmia or collateral hyperæmia. The lowered temperature, œdema, and gangrene are easily explicable by the stasis that is established, and the supervention of syncope from cardiac paralysis may be due to heightened arterial tension. The frequency with which aortic embolism is associated with mitral stenosis does not appear to be insisted on; but is easy of explanation, since it is especially in such cases that thrombi sufficiently large to block the vessel are found in the auricle.—*Lancet*, April 17, 1886.

DIFFERENTIAL DIAGNOSIS OF DISTENSION OF THE FALLOPIAN TUBES.—MR. JOHN W. TAYLOR points out what he thinks are the chief marks of similarity and difference between uterine myoma and tubal disease:

1. Menorrhagia may be common to both diseases, but in uterine myoma it is painless, in tubal disease it is very painful.

2. Moderate enlargement of the uterus (from 3 to 3½ inches) is present in tubal distension accompanied by hæmorrhage (as in most cases where metrorrhagia is a prominent symptom); an enlargement beyond this may generally be expected in myoma.

3. The tumor formed by distension of the Fallopian tube is always single or double, and is always posterior to the uterus; nodular myoma is usually multiple, and the situation of the outgrowths variable.

4. The tumor formed by a distended tube, even when chronic and quiescent, is always very tender to touch, whether that touch be from the examining finger of the surgeon, or from the passage of scybala through the rectum; a myomatous nodule, unless inflamed, is comparatively insensitive. Probably, for a similar reason, dyspareunia is a very general symptom of tubal disease, but is almost unknown in myoma.

5. The outline or shape of a distended tube is fairly constant, in possessing a longer and a shorter axis; that of nodular myoma is round or quite irregular.

6. The tumor caused by a distended tube varies in its firmness or consistency, and at some time or other will show signs of elasticity or fluctuation; that of nodular myoma remains hard.

7. Both a distended tube and myoma of the posterior uterine wall may sink lower in the pelvis by causing retroflexion of the uterus; but, apart from this, the former, although not adherent, tends to sink slowly by its own weight; the latter reaches a lower point only by increased growth.

8. When pregnancy occurs, the uterine enlargement being caused chiefly by the development of the muscular tissue of the uterus, a myoma of this tissue will be much more likely to be raised by the growing uterus than a distended tube, which is only adherent, and often but lightly, to its peritoneal investment.

The only other condition that is likely to be confounded with distension of the Fallopian tube is cyst or abscess of the ovary. A special form of cystic disease of the ovary is often, perhaps generally, combined with occlusion and distension of the tubes, and if the latter be correctly diagnosed in these cases, this is sufficient for every practical purpose. But ovarian abscess or cystoma of the ovary in an early stage, the associated tube remaining normal, needs rather careful differential diagnosis from a distended tube. I have found the chief point of difference to be this: that, in cyst or abscess of the ovary, a space can be found between the tumor and the uterus unoccupied by any swelling; in distension of the Fallopian tube, the tumor is continuous with the uterus. By this means I have on two or three occasions diagnosed a cystic condition of the ovary only, when tubal disease has been expected; a diagnosis which has been confirmed by operation.—*British Medical Journal*, April 17, 1886.

EFFECTS OF AN EXTENSIVE FRACTURE OF THE SKULL.—A case of extensive wound of the skull and brain is reported in the Russian *Herald of Forensic Medicine*. The patient was a man who had been struck by a piece of an anvil of about seventeen pounds' weight. The wound extended from half an inch above the concha of the left ear to the right parietal eminence. The fracture of the skull corresponded in length and position with the external wound. In many places it was splintered, the posterior edge of the fracture being raised above the level of the anterior edge. The whole wound was filled with crushed brain substance, partly gray and partly white. There was both motor and sensory paralysis of the right arm. The power of sensation in the right leg was diminished; the pulse was 80 and the respiration 20; the temperature was also normal. The patient was fully conscious and in a peculiarly placid state of mind, being pleased with everything. He forgot, however, a number of abstract nouns and all proper names; his memory for numbers was also affected, and he had forgotten how to read. The wound was dressed with antiseptic bandages, and completely healed in fourteen weeks. During this time ten splinters were removed. The symptoms of amnesic aphasia gradually passed off. The memory for abstract nouns returned in about a fortnight. The placid humor passed away, and the man became decidedly irritable and suffered from insomnia and headache. The paralysis of the leg passed off during the first few weeks. Sensation returned in the arm and movement also, and after three months contraction occurred. After the lapse of eight months the man was still unable to read, and complained of constant headache and great feebleness of memory.—*Lancet*, April 17, 1886.

AN UNUSUAL CARDIAC LESION.—M. DEJERINE made a communication, on Dec. 26, to the Biological Society of Paris, concerning an unusual cardiac lesion causing sudden death in two patients convalescent from typhoid fever. There were no cardiac symptoms during life. At the necropsy there was an absence of lesion, but examination with the microscope showed that the myocardium was broken up. Each fragment was constituted by an isolated muscular cell. There was neither fatty, nor putrid, nor pigmentary degeneration. In both cases the lesion of the myocardium consisted in a separation of the intercellular cement of Eberth, which in a normal condition unites the cells of the cardiac fibres. The phenomenon is observed in patients in an asystolic condition. It is due to the fact that the intercellular cement is dissolved by sarcolactic acid, which is formed in great abundance. There were no bacilli in the myocardium. Landouzy and Renaut have described this lesion in the myocardium subsequent to pericarditis.—*London Medical Record*, March 15, 1886.

SUTURES IN THE HEART.—A paper of Block communicated to the eleventh congress of the German Surgical Society, 1883, on "Wounds of the Heart and their Cure by Sutures," having attracted the attention of DR. PHILIPPOFF, of Kharkoff, he determined to make a series of experiments on dogs and rabbits for the purpose of satisfying himself of the truth of Block's assertion that sutures may, under certain circumstances, be applied to the walls of the heart. Though the Russian observer has not as yet concluded his investigations, he has published a preliminary note in the *Russkaya Meditsina* (No. 11) in which he states that the hearts of some animals will bear transfixion with a fine trocar or a needle, also that wounds of the heart in animals may be cured by means of sutures, but by no means always. He found, too, that the pericardium might be opened in dogs without any serious effects, but that wounds of the large vessels at their exit from the heart were invariably fatal.—*Lancet*, April 24, 1886.

CHICAGO ILLINOIS

SATURDAY, MAY 15, 1886

AMERICAN MEDICAL ASSOCIATION, THIRTY SEVENTH ANNUAL MEETING

The thirty seventh annual meeting of the American Medical Association was held in the Exposition Building at St Louis from the 4th to the 7th of May inclusive The number of delegates and members in attendance was unusually large, the registration showing about 1,100 present The facilities for registration were admirable, and everything under the care of the Committee of Arrangements well planned and judiciously executed The address of welcome by the Mayor of the city was appropriate and cordial, and the Chairman of the Committee, Dr Le Grand Attwood, discharged his duties to the satisfaction of all The President, Dr Wm Brodie, of Detroit, delivered his Address in good style, and was listened to with close attention to its close It was given to our readers in full last week Following the President's Address, came the report of the Committee on the Preliminary Organization of the Ninth International Medical Congress The Committee had held a regular meeting the day previous in a parlor of the Lindell Hotel and after learning the progress making by the Executive Committee of the Congress, also in session at the same time, they prepared a brief report for the Association Dr J S Lynch, of Baltimore, Vice President of the Committee on Organization, presented the report to the Association, which simply stated that after mature deliberation and several full meetings of the Committee, they had adopted the *Rules* necessary for the organization and business of the Congress, appointed the general officers of the Congress, the chief officers of the Sections, and a local Committee of Arrangements at Washington, and as under the Rules, the President, Secretary General, Treasurer, and Chairman of the Finance Committee of the Congress and the Presidents of the several Sections constituted an Executive Committee of the Congress with full power, all the further business and management of the Congress, including the filling of any vacancies that might now or hereafter exist, had been transferred to such Executive Committee

The report was, on motion, received, and adopted with a decided degree of enthusiasm, and without an audible negative vote As the very large hall contained at the time about 1000 delegates, representing the Profession of almost every State and Territory of the country, it ought to satisfy all parties at home and abroad, that the medical profession of these United States, in whose name the Congress was invited to meet in Washington, on the first Monday of September, 1887, is earnestly and unitedly engaged in making every necessary arrangement for the cordial reception of a great and truly International Medical Congress, at the time and place appointed

The harmony, good order and enthusiasm thus exhibited during the first session was continued throughout all the subsequent three days' proceedings and to the hour of final adjournment The several Sections were also supplied with a large number of papers and interesting topics for discussion, and the quality of their work will compare favorably with that of any of the general organizations of specialists in this country The full record of the proceedings, as furnished by the Permanent Secretary, will soon reach us, and will be given to our readers without further delay

DR DICKINSON'S WORK ON RENAL DISEASES

We have before us two copies of the third volume of DR HOWSHIP DICKINSON'S work "On Renal and Urinary Affections," the one published for the author by Longmans, Green & Co , of London, with the notification on the title-page that *all rights are reserved*, the other a mutilated reprint, a pirated copy of the result of years of earnest faithful work The latter is issued by a New York firm, as the August, 1885, number of "Wood's Library of Standard Medical Authors" The English edition contains 689 pages of reading matter, the mutilated edition 337 pages Nowhere in the American edition (though we must blush to call such an edition "American") is there any reference to the fact that it is the *third* volume of a work destined to become classical, but it is issued as though it is the complete work of Dr Dickinson

No work in any language has hitherto appeared which contains so much valuable matter in regard to renal and urinary affections as the work of Dr Dickinson He has been more than a decade in preparing the book for publication, and anyone who will give himself the pleasure of reading it will be convinced that the time has been well spent He has brought before the medical public a vast record of experience, and has embodied in the work a large number of most valuable records of clinical cases, occurring in his own practice and in that of other observers While at first blush it might seem that the subject could have been treated of in a much smaller number of pages, a careful survey of the book will show that it is far from being a diffuse work The clinical cases given cannot be looked upon as unnecessary padding, without exception they are interesting and valuable, and the reader will often wish that the author had given more cases The illustrations, as a rule, are good, and well represent what is intended to be shown While we are patriotic enough to wish that such a book could have been the work of an American author, we are not the less most willing to say that we must congratulate the profession on being able to obtain this monument of painstaking work and rich experience

In the mutilated reprint of this volume the American publishers have added the following note to the author's preface "The numerous cases cited in detail in the English edition of this volume have been omitted in this edition in order somewhat to reduce its size It will be perceived that the text of the work has been so prepared that this omission in no degree interferes with its continuity, nor does it limit its authority" Whether this is true will be seen later But the first question that arises is, Where have the reprinters obtained the medical education and authority that entitles them to abolish a large portion of a valuable book, without so much as "by your leave" to the author, and say to the profession We now give you an *edited* copy of Dr Dickinson's work, the original contains a large amount of extraneous matter, but we have cut this out, and at the same time retained the continuity and authoritative tone of the book? The answer is not direct, and may be read between the lines of the announcement quoted above Here is a good book by a foreign author, but it is too large for our "Library of Standard Medical Authors," foreign authors have no rights in America that we should respect, the book is too big, and while we are pirating it bodily we may as well cut it to suit ourselves Besides, very few of those who get our "Library" will buy the original work, and they will never find out that anything of value has been omitted

And now as to the omission which in no degree interferes with the continuity or limits the authority In the first place *eleven* illustrations are omitted in the mutilated reprint In the chapter on Renal Calculus, in speaking of ulceration of calculi into the stomach, is a quotation from Rayer, of almost half a page, which has been omitted altogether In the chapter on Chyluria thirteen and one-third consecutive pages of clinical reports have been omitted, in which, in the original, are two valuable tables In the chapter on Intermittent Hæmaturia or Hæmo-globinuria we find that 39½ pages have been omitted, with a valuable table, though of course such a small omission "in no degree interferes with the continuity" of the book In the chapter on Hæmaturia are records of five cases showing the association in infants of bloody urine with unsuitable food These records are omitted from the reprint, but the paragraph following the omission commences, *as in the original* "The circumstances of these cases," etc[1] In the chapter on Suppression of Urine is a full record of a case quoted from Mr Hutchinson, and a few pages further on the case is referred to by page reference The American editors (!) have omitted the record of the case, but guilelessly refer to it On the same page is a reference to a case reported by Dr Todd, but the record of the case is omitted in the revised American edition Dr Dickinson quotes in full a case from Taylor, of a man who had suppression of urine after taking two drachms of corrosive sublimate The *revisers* say, in a rather lonesome looking paragraph "Taylor relates the case of one John Wright, 38 years of age, who swallowed two drachms of corrosive sublimate, and an hour afterwards was received into Guy's Hospital" While it was perfectly proper that John Wright should have been received into Guy's Hospital after taking two drachms of corrosive sublimate, it would have been somewhat to the point to have said why he was carried there, and what became of him subsequently Taylor says that there was complete suppression of urine, that he survived for four days, and, what is especially interesting, the record of the autopsy is given But the professional experts who omitted this case (without interfering with the continuity of the work) evidently thought it sufficient to give only the name and age of the patient, the amount of the drug taken, and the name of the hospital

We have already said that preservation of continuity and non-limitation of authority demanded that eleven cuts should be omitted Would that some consideration had demanded that many more should have been omitted from the mutilated edition Dr Dickinson would doubtless be surprised to see that the ingenuity of the *editors* has added many things to his illustrations Emboli, thrombolic deposits, Florida moss, bee line capillaries, and scroll work have been generously supplied, doubtless at considerable additional expense to the editors One large cut is labeled "Tuberculous Kidney" It would be more in place in a horticultural guide as a hybrid sun flower

On summing up the total loss we find that eleven illustrations and *one hundred and fifty pages* (plus) have been omitted from the American edition! True, the pages omitted are reports of cases, but they are valuable and necessary for the proper comprehension of the subject Dr Dickinson is not a man who would pad a volume to make a show, and he is too busy to write for the purpose of killing time The author says in his preface "I am assured that much of any interest which may be found will be in the clinical and pathological cases," and the intelligent reader will endorse the assurance The editors, however, on account of a superior knowledge and acumen, have decided that the cases may as well be left out! If such things can be the time cannot come too quickly when an International Copyright law will lay its hands on those who seem to be destitute of all moral sense and obligation

THE INTERNATIONAL MEDICAL CONGRESS

A meeting of the Executive Committee of the Ninth International Medical Congress was held at the Lindell House, in St Louis, on the 3d inst, at which a large majority or the Committee were present.

Reports of sub committees were presented and much progress was made towards completing the details of the preliminary organization Dr N S Davis, of Chicago, was elected unanimously President of the Congress to fill the vacancy occasioned by the death of Prof Austin Flint Dr J A Grant, of Ottawa, Canada, was elected Vice-President in the place made vacant by the resignation of Dr R. Palmer Howard, of Montreal J B Hamilton, M D, Supervising Surgeon-General of the U S Marine Hospital Service, was elected Secretary General of the Congress to fill the place made vacant by the election of Dr Davis to the Presidency

James F Harrison, M D, Chairman of the Faculty of the University of Virginia and Professor of Medicine, Obstetrics and Diseases of Women, was elected President of the Section of Gynecology, J H Callender, M D, Professor of Physiology in the Nashville and Vanderbilt Universities, Tennessee, President of the Section of Physiology, A B Palmer, M D, LL D, Professor of Pathology and Practical Medicine in the University of Michigan, President of the Section of Pathology, and E Williams, M D, of Cincinnati, President of the Section of Ophthalmology In compliance with the earnestly-expressed wish of both the otologists and laryngologists, the latter were given a separate Section, with Wm H Daly, M D, of Pittsburgh, Pa, President, and Wm Porter, M D, of St Louis, Mo, Secretary

H O Marcy, M D, of Boston, at his own request, was transferred from the Presidency of the Section of Collective Investigation, Nomenclature, Vital Statistics and Climatology, to the Vice Presidency of the Section of Gynecology, and the vacancy occasioned by this transfer was filled by the unanimous appointment of Albert L Gihon, M D, U S N, a man eminently qualified to fill the place

These important appointments, with much additional work in regard to details, will enable the Committee at an early day to issue a second circular giving the Preliminary Organization of the Congress complete, including the foreign officers required by the Rules previously adopted, and such additional information as can be furnished by the Local Committee of Arrangements at Washington

THE VIRGINIA BOARD OF EXAMINERS

The report of the Virginia State Board of Medical Examiners, which is published in the May number of the *Virginia Medical Monthly*, will be of considerable interest to State medical examiners generally, and to all others who hope for a higher standard of medical education in this country The State legislatures, one after another, are passing medical practice acts, and we may now hope that within a very few years there will be an efficient board in every State

About a year ago we took occasion to notice the efficient work done by the Virginia Board At a meeting of this board, on April 7, there were thirty-four applicants, of these, twenty-five passed the examinations, one withdrew and eight were rejected Up to this time, then, about one hundred graduates have applied for licenses, and sixty six have succeeded in passing the examinations

Of the examinations, which are written, we may say that while they are not unnecessarily severe they seem to be unnecessarily long, and tend to be too much tests of physical endurance For example, there were six questions in chemistry, each with subdivisions, eight questions in anatomy, each one with subdivisions, five in hygiene, each with subdivisions, eight in physiology, fifteen in materia medica and therapeutics, some with subdivisions, six in obstetrics, five in practice of medicine, each with tedious subdivisions, and twenty in surgery, the last of which is, "Describe the methods of resuscitating the drowned?" Now, the plan of the examination announces that "the applicant is required to answer at least three fourths of the questions satisfactorily, and to show a fair general knowledge of all the branches upon which he is examined" The applicant may make only 33⅓ on a given branch, but must aggregate 75 per cent of the entire questions We notice that "some of the best examination papers that were presented kept the gentlemen busily at work from 10 or 11 o'clock Wednesday morning, till late hours at night each day until Friday and even Saturday" It would seem that the examinations might be quite thorough with fewer questions and a limited number of hours We can scarcely go amiss in saying that there are very few men in active practice who could answer 75 per cent of the questions within two days of twelve hours each It seems rather questionable if an examining board should ask such a question as "Give the anatomy and function of the lymphatic system," when physiologists and anatomists are not at all agreed as to the answer It is probable, too, that the student and examiner might differ as to the source from which the heart receives its nervous supply, and as to the phenomena of pancreatic digestion So, also, in describing the management of shoulder presentations, some obstetricians are positively at variance regarding the management of these cases However, the fault that we find is in regard to the number of questions It is better to be too severe than so lenient as to admit an unqualified man

SOCIETY PROCEEDINGS

AMERICAN SURGICAL ASSOCIATION

Seventh Annual Session, held in the Reading room of the Army Medical Museum, at Washington, April 28, 29 30 and May 1, 1886

(Concluded from page 528)

FRIDAY—APRIL 30—THIRD DAY

MORNING SESSION

THE PRESIDENT IN THE CHAIR

DR T F PREWITT, of St Louis, read a paper on

TRAUMATIC ANEURISM OF THE INTERNAL CAROTID ARTERY

He first referred to those cases of spontaneous aneurism of the internal carotid artery which are found in literature and, the frequency with which this lesion had been confounded with cynanche tonsilaris He had been unable to find more than one reported case of traumatic aneurism of this artery This was reported by Dr Wm T Briggs, of Nashville The aneurism in that case followed a stab wound and was operated on successfully

Dr Prewitt then described the following case E J, colored, 17 years of age, was shot by her husband, early in January, 1885 The weapon used was a revolver carrying a No 32 ball The shot was fired at a distance of two feet and entered the cheek over the malar bone, ranging backwards There was some profuse hæmorrhage at the wound of entrance There was no wound of exit The bleeding was controlled by compression There was hæmorrhage from the ear at the time, and this recurred on two or three occasions For some time after the accident the patient stated that there was some hæmorrhage from the mouth and nose on rising in the morning There was some swelling at the time which gradually increased until April the 2d, when she was seen by the speaker It then projected into the pharyngeal cavity and rested against the uvula, and extended externally from the anterior petrous portion of the temporal bone to the hyoid bone The swelling pulsated in every direction and gave thrill and bruit Immediately after the accident there was paralysis of taste and of the right side of the tongue, this continued Pressure upon the carotid artery arrested the pulsation in the tumor There was no difference in the pulsation of the two temporal arteries, the pupils were equal and respond normally to light There was persistent headache with sounds in the ears, which was increased by lying upon that side The voice was greatly interfered with, owing to paralysis of the right vocal cord The appetite was poor and the patient emaciated She was unable to swallow solids and fluids regurgitated when the attempt to swallow was made

With this history and with these symptoms it was decided that there was aneurism of the internal carotid artery, and that the vessel had been wounded near the carotid foramen, for nowhere else are the artery and nerve in such intimate connection

It was determined to at once ligate the common carotid artery The usual incision was made and the dissection continued until the artery was exposed A silk ligature was passed from behind forwards The vessel was then lifted to be sure that the pulsation was arrested before the ligature was applied Finding that it was, the vessel was then tied The pulsation was at first arrested, but in a few minutes it could be again felt In the absence of all precedent it was concluded to extend the incision upwards in front of the tragus and determine the feasibility of opening the sac and tying the distal end This was a forlorn hope, for the diagnosis was that the aneurism was seated just external to the carotid foramen An incision was then made below the ear and extended upwards back of the ear A cautious dissection revealed the fact that the sac filled all the space between the mastoid process behind and the condyles and ramus of the jaw in front It extended to the base of the skull, to which it was closely adherent

It was therefore impossible to reach the artery in that direction Further attempts were abandoned, the wound was closed, a drainage tube inserted and an antiseptic dressing applied During the following seven days the temperature varied between 101° and 103° On the eighth day, there was some hæmorrhage from an opening near the angle of the jaw This was repeated and she spat up some blood on the following day Examination showed a little coagulum at the angle of the jaw, which was removed and the left forefinger thrust into the opening No coagulum could be felt within the sac The attempt to detect the entrance of the artery with the finger failed In order to avoid the hæmorrhage which would follow the removal of the finger the sac was stopped with lint treated with iodoform This controlled the bleeding The patient gradually became weaker and died on the twenty-fifth day after operation from exhaustion Ten days after the sac was stuffed, epileptiform convulsions involving the facial muscles and the flexors of the forearm and hand appeared These continued at intervals until her death

The *post mortem* examination showed the ball in the posterior part of the sac The opening of the carotid artery was found close to the carotid foramen and seemed blocked up with clot The blood-vessels of the membranes of the brain were congested, particularly on the right side The inferior petrosal and lateral sinuses were filled with thrombi up to the torcular Herophili

The differential diagnosis of aneurism of the internal carotid artery from those of other arteries in this situation were then considered As regards operation in this case compression and ligation were considered, but compression was rejected on account of the urgency of the symptoms The patient was not a suitable one for this mode of treatment, being ignorant and irritable, and unfitted to endure the annoyances of this method of treatment Neither were skilled attendants available

Dr J Ford Thompson, of Washington, had never seen a case of aneurism of the internal carotid artery, but should think that the diagnosis would not be especially difficult It would perhaps have been better if the operation of Syme had been performed, or, if necessary, the suggestion of Guthrie might have been carried out, that is to make a section of the ramus of the jaw, to afford more room for dissection As this lesion is followed by certain death, his opinion is that it is the duty of the surgeon to perform the old operation, cutting into the sac and ligating the vessel at both ends

Dr William T Briggs, of Nashville, said that the case which he reported at a previous meeting of the Association was that of a young man stabbed in the neck Five weeks later the patient presented himself at the clinic with a swelling of the neck presenting all the evidences of aneurism He considered it to be a small aneurism of one of the branches of the external carotid artery that could be readily reached and ligated He made an opening large enough to permit the introduction of the finger, and at once found that the condition was more serious The hæmorrhage was controlled by stuffing a sponge into the sac and the common carotid ligated When the sponge was removed, the hæmorrhage was as free as before The opening in the sac was then enlarged, the opening of the artery having been found and controlled by the finger The vessel was then hooked up and a ligature applied above and below the sac The patient recovered and is still living in perfect health He thinks that in all cases where it is possible, the operation of Syme should be employed

Dr D Hayes Agnew, of Philadelphia, said that about three years ago, a woman presented herself at the University Hospital with a tumor as large as an orange just beneath and behind the angle of the jaw There was also a projection into the pharynx This tumor had grown slowly for eight months, and was attributed to a blow on the side of the head He considered it a case of aneurism of the internal carotid, and ligated the common carotid above the omohyoid muscle The pulsation was diminished, but it could still be felt He attributed this to the communication with the external carotid artery He then tied the superior thyroid and the lingual This stopped all pulsation The patient did well for two weeks, when pulsation again returned Pressure on the carotid of the other side controlled the pulsation, and he then placed a ligature around the primitive carotid of that side During his absence from the city, ulceration took place and a gush of blood into the pharynx occurred The resident stuffed the cavity, but the patient died eight days later, apparently from septic poison If he had been present when rupture occurred, he had determined to have laid the sac open and have tied above and below From the history of these cases he believes that in this condition the operation should be a formal one of section of the jaw, and then proceed to ligate above and below the sac

Dr A Vanderveer, of Albany, said that in December, 1882, a man 42 years of age, a farmer, was sent to him with a swelling of the neck which was diagnosed to be an aneurism of the internal carotid artery It was attributed by him to forced motion of the head to one side which was required in a certain part of his work It was determined to first try compression This was faithfully carried out, and at the end of six days the swelling was much diminished and the tumor in the pharynx seemed more solid He then went to his home, but returned one month later, the previous condition having returned Compression was again tried, and at the end of five days there was a marked diminution in the size of the tumor He again returned home and continued in apparently good health for four or five weeks, when he suddenly complained of a severe pain in his head and fell dead An autopsy was made, but no satisfactory explanation of his death could be found The physician was inclined to attribute it to apoplexy

Dr L McLane Tiffany, of Baltimore, said that in the case reported by Dr Prewitt there was no room for a distal ligature In this case, however, it might have been possible to apply a compress, pressing the artery against the base of the skull

Dr T F Prewitt agreed with those who had taken part in the discussion that the old operation is the proper one for traumatic aneurism where it is possible to apply it In this case this could not be done If the circumstances had been suitable, he should have tried compression, but the symptoms were too urgent to permit of this

Dr Roswell Park, of Buffalo, exhibited a

TRACHEOTOMY TUBE

This was a bivalve instrument, the blades opening laterally and provided with an obturator permitting its ready introduction The great advantage claimed for the instrument was the ease with which it could be cleansed

Dr Park then reported a case of

LIPOMA TESTIS, OR A LARGE ACCUMULATION OF FAT IN THE TUNICA VAGINALIS

Lipomata of the spermatic cord are rare enough to always attract attention, but lipomata of the testicle are of such exceeding rarity that, believing that he had had a case which deserved this designation, he desired to put it on record

J. P, age 40, was first seen in September, 1885 For eighteen months the patient had noticed a slow but continuous enlargement of the right testicle This was almost painless, but caused inconvenience by its weight At this time the tumor had reached the size of a cocoanut

Examination showed the scrotum to be filled with a large mass, the testicle being crowded into a small space at its upper part This mass was solid, yet soft and not tender Obscure fluctuation was noticed, but no fluid was obtained upon explorative puncture The patient's general appearance excluded all idea of malignancy The scrotal integument moved with perfect freedom over the tumor

On October 4 the patient was operated on A free incision through the tunica vaginalis revealed a mass of densely packed fat which was slightly adherent, but was turned out without difficulty On separating the lobular masses by the fingers, the right testicle was found not merely imbedded in its upper part, but incorporated by apparently intimate tissue connection It was supplied with blood both from the testis and from the cord The cord seemed to pass for a distance of two inches through the mass before reaching the testicle No evidence of pus or present hernia could be found, the ring and canal being no larger than on the opposite side Finding the fibrous trabecula and blood vessels radiating from the testicle to the fatty mass so numerous and distinct, it was decided to remove the whole *en masse*, which was done The patient recovered without incident After removal the mass weighed three pounds It was not possible to decide the exact origin of the fatty growth, whether it had started from the cord or from the testicle

The literature of this subject is very meagre, the author being able to find but three similar cases on record Kimball (*Boston Med and Surg Journal*) and Jobert (*Gaz Med de Paris*, 1850) report authentic cases Deguise also reports a case (*Ann de la Soc de Chir* ix) in which the tumor was as large as an adult head, and had been growing for twelve years Numerous authors state that lipoma of the cord may extend downwards and may spread over testicle, and it is possible that this case may have begun in that way, but there was nothing to indicate such an origin The rarity of the lesion coupled with its pathological interest and the obscurity which attends the diagnosis, was the author's reason for presenting the case to the Association

Dr Park also read a paper entitled

NEPHRECTOMY ON A PATIENT TWENTY-THREE MONTHS OLD

B B, born October 4, 1883, appeared at birth to be perfectly healthy During the following winter the nurse noticed an enlargement in the right side of the abdomen, and the attention of the attending physician was called to it

July 31, 1885, the attention of the writer was called to the child, who appeared to be perfectly healthy There was a history of steady enlargement of the growth The bladder was examined with the sound, but no evidence of calculus was found The urine contained numerous crystals of triple phosphates, otherwise normal Examination of the abdomen revealed a firm resisting tumor about the size and shape of the fœtal head at term, occupying the right half of the abdominal cavity A portion of the fluid was removed and examined, with negative results The diagnosis was fibro cystic tumor of the right kidney, probably of congenital origin Five weeks later the tumor was found to have increased decidedly in size, and operation was decided upon

The operation was performed September 15, 1885 An incision was made in the right semi lunaris, slight adhesions were found The peritoneum covering the growth was incised and the tumor shelled out without much difficulty The pedicle was tied and dropped into the abdominal cavity On the twelfth day the patient was removed to his home, and now, seven months after operation, is perfectly well The tumor proved to be a fibro cystic tumor of the right kidney, the cystic element predominating Immediately after removal it weighed four pounds

In searching the literature of this subject, the writer had been able to find but three cases in which the age of the patient approximated that of the one now reported These cases were respectively, one, 2¼ years, recovered, one, 2½ years, died, and one at 11 months, died The case reported therefore appears to be the youngest who has survived nephrectomy, he being 23 months old at the time of operation The abdominal incision in this case was made not from choice but from necessity, the tumor being altogether too large for extraction through a small opening in the lumbar region

Dr W W Keen, of Philadelphia, then read a paper on

STRETCHING OF THE FACIAL NERVE

He first related a recent case in which he had done the operation, and added a table of the twenty one cases so far reported

His own case was that of a woman, sent to him by Dr Sinkler, aged 48 years She was admitted to the Woman's Hospital April 1, 1886 She had had severe attacks of nervous trouble in early childhood, and had twice been paralyzed Five years ago coincident with menstrual disturbance her right eyelid began to twitch, and in six months the whole face and the platysma were incessantly in spasm, which was increased by mental or muscular effort, such as speaking or being spoken to Later this was accompanied with constant pain

In June, 1884, the right infra orbital had been resected with partial relief for only six weeks Not long after the twitching extended to the right side and leg

April 2 Dr Keen cut down on the seventh nerve by an incision behind the right ear, displacing the parotid gland forwards and getting access to the nerve just after its exit from the stylo mastoid foramen Imbedded in connective tissue, it required considerable search and dissection to lay bare the nerve in this case The exact point of its entrance into the parotid was quickly discovered by a very weak current of electricity, one electrode being placed on the cheek and the other consisting simply of the wire being touched at successive points from above downwards The trunk was then laid bare and stretched, the force being estimated at four or five pounds, just short of lifting the entire head Total facial palsy followed, with relief not only from the spasms in the face and neck, but also of that in the side and leg The wound healed in four days, when the sutures were removed, the highest temperature having been 100 4° The operation was done twenty five days ago, and so far there has been no return of the spasms and the patient was delighted with the the result, the palsy being a grateful relief from the spasm

Dr G B Massey had examined the case electrically and found the reactions of degeneration The later history of the case will be reported at a subsequent meeting

Next a table of the other twenty cases so far reported since Baum, in 1876, first stretched the facial nerve, was given, with remarks upon the operation The paralysis always disappears no matter how severe the nerve has been stretched, and while the spasms often return, they are lessened in severity In fourteen of the cases the spasms recurred within a week in three cases In five others, absolute relief extended over three weeks to five months, the improvement in four of them lasting much longer In the remaining six cases the relief extended from four months to a year, with improvement still existing in three of them As a palliative operation, therefore, it would seem to be indicated, while of the five cases reported "cured," two had continued three months, three had remained well for from two and a half to five years Two of the twenty one cases were too recently reported to give the final results

The speaker preferred Baum's method of operating decidedly to Heuter's, in which the nerve is reached through the parotid gland He bandages the lower jaw and gives fluid food for three or four days in order to keep the parts quiet while healing He called attention to two cases in which a palsy existing prior to the operation was benefited by the nerve stretching, both electrical and voluntary control being obtained to some extent, and he suggested that in persistent facial palsy, stretching of the facial nerve be tried as a therapeutic operation

Dr C H Mastin, of Mobile, read a paper on

SUBCUTANEOUS DIVISION OF URETHRAL STRICTURE

The history of the operation for external urethrotomy was first considered, and next was described the various methods which have been proposed for its performance The objections to these were then gone into at length The main objection to most of them is that they leave an open wound in the perineum to heal by granulation External urethrotomy is called for only under special circumstances It has been laid down as a rule that where water can escape through a stricture, the surgeon should always by patience, be able to get an instrument through the stricture The speaker thought that there were exceptions to this rule

The indications which render the operation necessary are

1 The impossibility of passing a sound into the bladder through the urethral canal, where a firm organic stricture blocks up the urethra and where dilatation or internal urethrotomy are not available

2 In cases where a tight stricture has ruptured, and an abscess has formed Under such circumstances it is necessary to open the abscess and it may be well to carry the incision further and lay the stricture open

3 Certain cases of old tight stricture complicated with urethral fistulæ, through which urine is passed in the act of urination In almost all these cases, however, as soon as the lumen of the tube is restored, the fistulas heal The writer prefers internal section in such cases

4 A most important indication which may arise is rupture of the urethra by a blow, the effects of which are violent and severe

5 Traumatic stricture, that is where the stricture is the result of direct injury to the urethra In these cases ordinary dilatation is inefficient and internal urethrotomy is often of little or no benefit

6 A calculus impacted behind a stricture may be an indication for external section

7 When extravasation of urine has occurred from sudden rupture of the urethra, and which is followed in a short time by extensive sloughing of the penis, scrotum and groin

8 The last indication is one in which Mr Reginald Harrison recommends combined external and internal urethrotomy with the introduction of a large tube

Having decided that external section is required, the question is, which operation gives the best prospects of success and is most readily performed The claims of the operations proposed were then considered

The author next described the operation which he had employed with entire *satisfaction since 1868* The incision is a very small one, made anterior to the stricture The patient, being properly prepared, is put in the ordinary position for cystotomy An anæsthetic is administered, a tube, open at both ends is then passed down to the stricture, this protects the walls of the urethra and puts on the stretch the face of the stricture The tube is filled with small whalebone probes, and one after another is tried with the hope that one will enter the stricture This being accomplished, the tube and probes are removed The probe engaged in the stricture is then pushed forward and a Wheelhaus sound carried down to the stricture, an incision one-half inch in length is then made in the anterior wall of the urethra on the groove of the sound, the sound is withdrawn a short distance and the whalebone bougie sought for as it passes through the stricture and drawn out of the original wound Over the probe a gorget is passed, having its blade upwards, this is passed downwards, cutting the stricture on its superior face, a catheter is then passed along the entire urethra into the bladder and the urine evacuated The stricture is then examined, to determine whether or not any points of narrowing still remain If they are, they are divided

If, in the first instance, it is found impossible to pass the whalebone bougie, a staff with a deep groove is passed to the stricture, and a small opening made, a whalebone bougie is then passed through the stricture, and the operation is complete, as in the previous case After operation, a full-sized ordinary soft catheter is introduced to the prostratic portion of the urethra, but not into the bladder, the patient is put to bed, on the left side, and directed to push the catheter into the bladder when the desire to urinate is felt, and to withdraw it beyond the neck of the bladder, but not through the stricture after the urine has been passed This is used only for the first twenty-four or thirty six hours, to protect the wound from the contact of the urine The speaker was opposed, on general principles, to allow a catheter to remain in the bladder, at the end of the time mentioned, the catheter is dispensed with Immediately after the stricture has been incised and the calibre of the urethra restored the external wound is closed with three fine pins passing sufficiently deep to grasp the walls of the urethra, these are removed in from four to six days In the course of eight or ten days the patient is able to return to his work The maximum calibre of the urethra is restored by the use of graduated sounds

The advantages of this operation are the short time of confinement for the patient, the freedom from hemorrhage the quick union by primary adhesion, and the small amount of cicatricial tissue left

Dr Dunott's experience in dealing with so called impermeable or impassable stricture has not been small, he had been able to deal with them even when there was great induration, almost without exception by the ordinary internal urethrotomy operation In fifty or sixty cases seen within the last twelve years, he had been compelled in but one or two instances to perform external section He thought the main reason that external urethrotomy is so frequently necessary is absence of patience on the part of the surgeon It seemed to him almost without exception that where one drop of urine will pass through the urethra, a guide can be gotten in, provided the surgeon has the patience to wait for it

Dr J Ewing Mears offered an amendment to the By-Laws, providing for the appointment of a committee, of which the President shall be chairman, to have charge of the preparation of the scientific work of each session Laid over until the next meeting

The President announced the following committee on the proposition looking to the formation of

A CONGRESS OF AMERICAN PHYSICIANS AND SURGEONS

Drs C H Mastin, Charles T Parkes, J Ford Thompson, J Ewing Mears, and N Senn

The following were elected

OFFICERS FOR THE ENSUING YEAR

President — Hunter McGuire, M D, Richmond, Virginia

Vice-Presidents — T F Prewitt, M D, St Louis, and J W Gouley, New York

Secretary — J R Weist, M D, Richmond, Ind

Recorder — J Ewing Mears, M D, Philadelphia

Treasurer — P S Conner, M D, Cincinnati

Council — Drs Hunter McGuire, John S Billings, L McLane Tiffany, R A Kinloch, and Moses Gunn

The following were elected

HONORARY MEMBERS

Foreign — Sir William MacCormac, *American* — Prof Henry J Bigelow

Active Members Elected — Drs H H Mudd, St Louis, and Joseph Ransohoff, Cincinnati

Time and Place of Next Meeting — The second Wednesday in May, 1887, at Washington

---

CHICAGO MEDICAL SOCIETY

Stated Meeting, May 3, 1886

The President, E J Doering, M D,
in the Chair

Dr M P Kossakowski exhibited a case of

DOUBLE HARE-LIP AND CLEFT PALATE IN AN INFANT

He promised a subsequent report of the case

Dr H Gradle read a paper on

PURE DRINKING WATER

(See page 544)

Dr Long asked if it is demonstrated whether the bacteria in our dringing water comes from the sewerage or from the air

Dr L Curtis said there is no doubt that water absorbs a great number of bacteria from the air, and that these may gain entrance into the circulation through the digestive tract as well as through the respiratory tract He said there is no doubt of the possibility of malarial germs being introduced into the system by means of drinking water

Dr R Tilley wished to know if it has been actually demonstrated that the bacillus tuberculosis finds its way through our sewers into the lake and drinking water We are not justified in saying that our water contains this element of danger until it has been demonstrated

Dr J Zeisler asked if Dr Gradle had examined the Waukesha waters and found bacteria in them

Dr Gradle closed the discussion by saying he took pains not to state in his paper whether he thought the disease germs found in the water were introduced by means of the sewerage or air It is not a vital point so far as the use of the water is concerned, although if it is decided that these bacteria are introduced by means of the sewerage and not the atmosphere, it would have a bearing on the question of where to dispose of our sewerage However, there is no doubt but bacteria are introduced into large bodies of water by means of dust, vegetation, and decayed leaves, and there is no reason to believe that the bacteria found in our water is derived from the sewerage alone A Russian chemist had examined the water found at St Petersburg, and found that at a distance from the city the number of bacteria per cubic centimetre was considerably less than near the city Dr Gradle has examined water obtained from Lake Michigan about thirty five miles from Chicago and had found about the same number of bacteria per cubic centimetre, but a less number of varieties than in city water He believed the spores of typhoid and tuberculosis may find entrance into our lake water and become causes of disease in individuals who are not prepared to resist their attack Dr Gradle had never examined the Waukesha waters, but he had examined water from a spring on his own farm, which he believed to be as pure as Waukesha water, and had found only fifteen to twenty bacteria per drop, and only three varieties He believed that spring waters are the purest, as the bacteria they contain cannot be due to sewerage

Dr W H Lyford read a report of a case of

SCLERODERMA

A girl, æt 10 years, apparently healthy and of good family history Five years ago she received a shock from a lightning stroke Shortly afterwards her parents noticed, under the surface of the skin over the outer region of the left forearm, a delicately traced symmetrical figure, branching and ramifying in purplish colored lines with singular regularity Dr Lyford believed the lightning had paralyzed the cutaneous branches of the musculo spiral nerve, and caused congestion of these filaments, with the marking as a result In due course of time the skin has undergone the changes that take place in scleroderma There is hyperæsthesia accompanied by pain, especially at night The patch is also now slightly elevated above the surrounding healthy integument, and is only slightly movable, while at the elbow it is attached to the fascia and sheaths on the tendons, thus interfering somewhat with the movements of the forearm

Dr J Zeisler said he had seen four cases of scleroderma, two of general scleroderma and two of partial scleroderma The first two cases he saw in a clinic of Kaposi Their appearance was striking In scleroderma the features of the face are immobile, and therefore the patient cannot express the emotions The skin and underlying tissues seem to grow together The cases of partial scleroderma he had seen in this city In one patient the patch of scleroderma was a ribbon like band behind one ear, pinkish in color, immovable upon the underlying tissues The other case was a lady æt 50 years, who noticed her right mammary gland was becoming hard, large, and the nipple contracted There was no pain in the breast nor were the axillary glands involved The skin was hard and adherent to underlying tissue A similar condition was observed in a patch of skin on the right arm Kaposi states the majority of cases of scleroderma occur in females The best treatment for scleroderma is massage and galvanic electricity

DOMESTIC CORRESPONDENCE

LETTER FROM NEW YORK

(FROM OUR OWN CORRESPONDENT)

Cuneiform Osteotomy for Congenital Talipes Equinus—Compound Comminuted Fracture of the Femur—Cholecystotomy for Abscess of Gall-bladder and Closure of Cystic Duct

At the last meeting of the New York Surgical Society the proceedings were of unusual interest and variety of scope Dr Charles T Poore presented a patient, the subject of congenital talipes equinus, on whom he had performed cuneiform osteotomy with the most successful results The operation, which consisted of the removal of a V-shaped piece from the outer aspect of the foot, as advocated by Davy and others, was not performed until after the failure of all attempts to change the position of the anterior portion of the foot, including the use on several occasions of Bradford's instrument for forcibly rectifying this deformity The patient was observed to walk with but a slight limp, and Dr Poore stated that he was regaining motion in the ankle joint, while there was no pain whatever about the foot

Dr George A Peters then presented a patient, a lad of 16, whom he had treated at St Luke's Hospital for compound comminuted fracture of the femur The injury was caused by being kicked and trampled upon by a horse, and about four and a half hours after it was received Dr Peters operated as follows The surface of the limb was thoroughly cleansed and rendered aseptic An incision two and a half inches long was made on the external opening down to the bone A large piece of the anterior surface of the shaft of the femur was then found to be chipped off, though attached at its lower end by the periosteum This was removed, and found to measure six inches in length, by one inch in width Another small loose piece was also found and removed The two beveled surfaces of the femur were then united by two silver wires, after which the wires were twisted, and the ends left projecting from the external wound A rubber drainage-tube was inserted, and the incision closed with a continuous catgut suture The wound was well dusted with iodoform, and a dressing consisting of iodoform gauze, bichloride gauze, and a Lister bandage, applied The foot was slightly everted, and a long Liston splint, reaching from the toes to the thorax, bandaged on. Finally, Buck's extension, with a weight of five pounds, was ordered, and the patient placed in Ludlow's modification of Crosby's fracture bed. More than seven months afterwards a piece of the lower fragment of bone, measuring two and a half inches by seven-eighths of an inch, was removed from the sinus left, and it was found to contain two of the drill-holes made by Dr. Peters. The patient was discharged, after remaining in the hospital for eight months, with good union and only about one inch of shortening. The good result in this case, Dr. Peters thought, was largely due to the fracture bed referred to, which is much used in St. Luke's.

The paper of the evening was by Dr. Joseph C. Hutchinson, of Brooklyn, and was entitled *A Case of Closure of the Orifice of the Cystic Duct by a Gall Stone, Abscess of the Gall bladder, Cholecystotomy, Recovery.* This was a very obscure case, and the diagnosis was not positively determined until laparotomy was resorted to. The history of the patient, whom Dr. Hutchinson saw in consultation with Dr. Bristow, of Brooklyn, was as follows:

Mrs. S., a widow, about 40 years of age, about twelve years before coming under his observation, began to have paroxysms of severe pain in the "pit of her stomach, running through to the back," coming on suddenly, and lasting usually about twenty minutes, but occasionally for an hour. There was sometimes an interval of a year or more between the paroxysms; then, again, they would come every day, and even several times a day. As a rule, she said, the paroxysms were more frequent when she was in ill health or became wearied by any unusual exertion. They were not attended by nausea and vomiting or febrile disturbance, and were not followed by jaundice. In July, 1884, when she first came under Dr. Bristow's care, a tumor about the size of a man's fist was discovered in the right side of the abdomen, below the level of the umbilicus. Pressure upon it produced a sense of oppression and shortness of breath, but no pain was developed. There was, most of the time, a dull aching sensation in the region of the tumor, and to get relief the patient would involuntarily apply the hand and move the tumor to one side or the other, which she could do for about two inches. At that time she had been free from the paroxysmal attacks of pain for about two years. She was anæmic, and complained of exhaustion; but was able to attend to her household duties. The bowels moved regularly, and the fæces were normal in color and consistency. There was no suspicion of hepatic disease. She had never had jaundice; chemical and microscopic examination of the urine showed that it was normal in all respects; and she did not have rigors or fever.

Dr. Hutchinson first examined the tumor in January, 1885. It then extended from a line on or level with the umbilicus, and an inch to the left of it, across to the right lumbar region, and downwards to within two inches of Poupart's ligament. It was irregularly rounded, fluctuated distinctly, was movable from side to side, and was painless. There was no dulness between the tumor and the liver. The uterus was normal in size.

The diagnosis was, cystic tumor of the ovary, and she was operated on, after an appropriate course of preparation, on May 18, 1885. After the patient had been placed under ether, Dr. Hutchinson made another careful examination of the tumor, and a question then arose as to the correctness of the diagnosis made. Under the circumstances, therefore, he made an exploratory incision through the *linea alba*, beginning one inch below the umbilicus, and extending it downward two and a half inches. When the abdominal cavity was opened the cyst, white in color, was brought into view, and a steel sound, first dipped in hot water, was passed in, and swept around the tumor, with the result of proving that there were no adhesions. With a large trocar one pint of laudable pus was then withdrawn from the sac, and microscopic examination subsequently showed that there were no cholesterine crystals, or other elements to indicate that the fluid came from the gall bladder.

The cyst was seized with forceps and drawn up into the wound, in order to prevent its contents from escaping into the abdominal cavity. In manipulating the sac Dr. Hutchinson discovered that it contained a rounded solid body which, on being removed by the finger, after the opening made by the trocar had been enlarged, proved to be a gall stone. On further exploration, another was found, pointed on one side, the point fitting into the orifice of the cystic duct, completely occluding it. This condition, he said, explained the absence of jaundice, of clay colored stools, and of bile pigment in the urine. An effort was made to explore the cystic duct with a probe; but its orifice could not be discovered. Two fingers were then carried along the collapsed gall bladder to the under surface of the liver, to ascertain, if possible, whether the ducts were free from calculi or other obstructions; but none could be found. The sac was well irrigated with warm water, and the edges of the opening into it were stitched with five interrupted silk sutures to the upper end of the wound in the abdominal walls, leaving the opening into the gall bladder quite free. The edges of the peritoneum were closed by a continuous catgut suture, and the remainder of the abdominal tissues by interrupted silk sutures, carbolized, carried down to the perineum, but not through it. The walls of the gall-bladder were one-fourth of an inch thick. A glass drainage tube was introduced into the gall-bladder, and the wound was dressed with oiled lint, sprinkled with iodoform, and covered with marine lint and a bandage. The gall bladder was irrigated daily for four or five days, through the drainage-tube, with a one half per cent. solution of carbolic acid.

Bile began to flow from the drainage tube on the second day after the operation, and it continued to flow from the fistulous opening for six weeks, when the latter was entirely closed. After the operation the temperature once reached 101°, but it was promptly reduced to 99° by the application of the abdominal rubber coil. The patient was allowed to get up on the twenty first day. Microscopic examination of the calculi removed showed them to be largely composed of cholesterine.

In some concluding remarks, Dr. Hutchison said that an interesting feature of the case was the uncertainty of the diagnosis and the absence of symptoms calling attention to the gall bladder The symptoms had been confined to paroxysmal pains in the epigastric or hepatic regions for nearly three years, while the pain which the patient had in the early history of the case, referred to the pit of the stomach and extending to the back, although irregularly paroxysmal was unattended by nausea and vomiting, and was not followed by jaundice or clay colored stools, symptoms which were considered almost pathognomonic of the passage of biliary calculi Aspiration, instead of throwing any light on the case, would have made the nature of the tumor still more uncertain, because none of the elements of bile would have been found in the fluid thus removed, which, as was shown at the time of the operation, would have consisted of pure pus Acupuncture might have aided in the diagnosis, but in so large a collection of pus, it was not probable that the needle would have found the calculi

Although cholescystotomy was unpremeditated in this case, Dr Hutchison said that he would, in a similar operation, with the experience which this one had furnished, pursue the same plan The incision in the *linea alba* is attended by less hemorrhage than the usual incision along the margin of the ribs, and experience has shown that an enlarged gall bladder can be reached quite as readily by one incision as the other Suturing the opening in the gall-bladder to the abdominal walls, and establishing a biliary fistula should, he thought, be preferred to sewing it up and leaving it in the abdominal cavity,—*first*, because there would be less danger of the escape of bile into the perineal cavity, and, *second*, if the cavity cannot be found at once, they may be searched for subsequently, or be spontaneously discharged through the fistulous opening, which usually heals in a few weeks, Dr Hutchison last saw the patient January 25, 1886, when she felt well, and was greatly improved in appearance This case afforded another illustration of the difficulty in always positively diagnosticating abdominal tumors, and of the importance of being prepared, before operating, for unexpected conditions

Dr T M Markoe, remarked that he now had a case which he was carefully watching with a view to operating It was quite different from Dr Hutchison's, however, in the fact that the distended gall-bladder could be made out very clearly He thought jaundice was rather the exception than the rule in these cases P B P

MISCELLANEOUS

The Florida Medical Association will meet in Palatka, Putman Co , on Tuesday, May 18

MEDICAL SOCIETY OF THE STATE OF CALIFORNIA —The sixteenth annual session of the Medical Society of the State of California, was held in San Francisco on the 21st, 22nd, and 23rd of April The attendance was larger than that for many years One hundred and forty five new members were admitted There was a marked increase in the number of voluntary papers

The following officers were elected for the ensuing year President, W S Thorne, First Vice-President, R H Plummer, Second Vice-President, W F McNutt, Third Vice-President, A G Anthony, Fifth Vice President, W R Cluness, Treasurer, G C Simmons, Secretary, W A Briggs, Assistant Secretaries, J H Parkinson and L M F Wanzer, Board of Censors—William Watt Kerr, T B DeWitt, H S Orme, A G Anthony, G G Tyrrell, Board of Examiners—James Simpson, R H Plummer, C G Kenyon, C H Steele, C E Blake, W F McNutt and William M Lawlor

The next session will be held in San Francisco, commencing on the third Wednesday in April, 1887

ILLINOIS STATE MEDICAL SOCIETY —The annual meeting of the Illinois State Medical Society will be held in Washington Hall, Bloomington, on May 18, 19 and 20, beginning at 11 A M , on Tuesday, May 18

The Railway fare for delegates and members from Chicago is $5 00 for the round-trip Delegates from other States will pay full fare coming and one cent a mile returning

Arrangements have been made for commutation fare at the Ashley House, Phœnix Hotel and Hotel Roberts, each within one or two squares of Washington Hall

Trains leave Chicago as follows Illinois Central 2 50 P M , arriving in Bloomington 9 P M Chicago and Alton, 8 45 A M , 12 30 P M , and 11 20 P M , (with sleeper) arriving at Bloomington at 1 40 and 5 40 P M , and 6 30 A M

HYDROPHOBIA IN RUSSIA —In the *Russkaia Meditzina*, No 8, 1886, p 141, Dr A Burtzeff, of Totma, Valogda Government, writes that, on November 22, 1885, seven adult men were bitten by a rabid wolf, which rapidly visited different parts of the town, and then escaped All the patients were immediately attended to at the local hospital, their wounds being washed out with a strong solution of carbolic acid, energetically cauterized with caustic potash in substance, in addition, ligatures, lotion of caustic potash, and chloral hydrate in scruple-doses internally were used In three of the patients, hydrophobia appeared on the thirty-fourth, thirty-sixth, and thirty-eighth days, the cases ending fatally in thirty-seven and a half, seventy-one, and sixty five hours Subcutaneous injection of curare did not give the slightest relief to any of the patients According to Dr Burtzeff, the symptoms and course of the disease closely tallied with those described by Dr Bristow, that is, there were present intense pain in the wounds, general hyperæsthesia, violent dyspnœa of the muscles of deglutition and respiration, thirst, with inability of swallowing either solids or fluids, affective insanity etc In two of the patients, a tendency to bite everybody, and to gnaw everything within their reach, was observed The remaining four patients bitten are still in good health In conclusion, the author lodges a complaint against the freedom with which wolves, rabid and healthy alike, are allowed to run and ramble about the town, no measures to prevent this being taken by the authorities Probably, the latter will be aroused when a sagacious wolf bites or devours one of their number Till then, the wolves will remain unmolested, and privileged in their possession of freedom —*British Medical Journal*, April 24, 1886

Dr Edward F Wells, formerly of Minster, Ohio, has accepted the Chair of Materia Medica, Pharmacology and Clinical Medicine in the College of Physicians and Surgeons of this City, and has removed from Minster to 148 Dearborn Ave , Chicago

The Pasteur Commission —The Commission of Inquiry into the system carried out by M Pasteur to prevent the development of hydrophobia, which has been appointed by the British Government, has now commenced its investigation The Commission consists of Sir H Roscoe, M P , who moved for the appointment of the Commission in the House of Commons, Sir James Paget, F R S , Dr Burden Sanderson, F R S , Dr Quain, F R S , Principal Veterinary Surgeon G Fleming, of the Army Veterinary Department, Dr Lauder Brunton, and Mr Victor Horsley, F R C S , of the Brown Institute, the latter acting as Secretary to the Commission Sir H Roscoe, Drs Brunton and Sanderson, and Mr Horsley are now in Paris, and before long the public may look forward to the issue of a report which will enable them to appreciate the value which properly attaches to the processes adopted by M Pasteur The composition of the Commission renders it quite unnecessary to indicate the nature of the evidence which should be sought for, but we may say that, so far, no reports which have come under our notice have given sufficient evidence that their compilers have eliminated the many sources of error which have to be dealt with before any trustworthy opinion can be expressed as to the methods carried out in Paris —*Lancet*, May 1, 1886

The Progress of Beer-Drinking in America —Beer, it would seem, is rapidly replacing the fantastic "drinks" for which the United States have earned a reputation, and is in a fair way to become the national beverage The quantity of beer now consumed is, in proportion to the population, eleven times as great as it was forty years ago Some, perhaps not altogether disinterested, persons appear anxious to get up a scare about beer, and are endeavoring to prove that it is a beverage peculiarly dangerous to health, causing degeneration of the heart, the liver, and the kidneys The evidence, however, in support of this charge is not overwhelming, it is said, for instance, that the hearts of the men of Munich are larger than those of other people, and more ready to undergo fatty degeneration, and that the number of people who die of Bright's disease, in New York, has increased since beer became a popular beverage Evil tales are told of its adulteration, but they have not found much confirmation in the analyses made for the State Board of Health, and there is reason to fear that even whisky is sometimes tampered with On the whole, this change in the drinking habits is a matter for congratulation, even if it be true that he who drinks beer thinks beer Still, our somewhat mercurial cousins may be none the worse for the infusion of a little Teutonic solidity There is, however, one kind of ale which is best of all—that of Adam —*Brit Med Jour*, May 1, 1886

American Medical Association —The Thirty-eighth Annual Meeting of the American Medical Association will be held in Chicago commencing on the first Tuesday in June, 1887, under the Presidency of Dr E H Gregory, of St Louis Much of the success of the St Louis meeting is due to the efficient work of Dr LeGrand Attwood, Chairman of the Committee of Arrangements The Chairman of this Committee for 1887 is Dr Chas Gilman Smith, and it may be predicted that he will prove a most fitting successor to Dr Attwood

The social features of the St Louis meeting were of the most brilliant description With a musical entertainment at the Exposition Building on Tuesday evening, a grand reception at the Merchants' Exchange on Wednesday, six receptions at private houses on Thursday evening, and an excursion on the "Chouteau," one of the largest steamers on the Mississippi, on Friday afternoon, the members and delegates actually labored under embarrassment of social riches The St Louis meeting will long be remembered as one of the most pleasant in the history of the Association

Spanish Rags —The prohibition of the importation into England of rags from Spain has been extended for a period of four months from May 1

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY FROM MAY 1, 1886 TO MAY 7 1886

Major Francis L Town, Surgeon granted leave of absence for eight months, with permission to go beyond sea, to take effect when his services can be spared by his department commander (S O 101, A G O , April 30, 1886)

Capt Wm J Wilson, Asst Surgeon, died May 2, 1886, at Plattsburg Bks , N Y

First Lieut Geo F Wilson, Asst Surgeon, ordered for duty at Ft Shaw, M T (S O 37, Dept Dakota, April 26, 1886

First Lieut A S Polhemus, Asst Surgeon, relieved from duty at Presidio of San Francisco, Cal , and ordered for duty as Post Surgeon, Ft Halleck, Nev (S O 28, Dept Cal , April 26, 1886)

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U S NAVY DURING THE WEEK ENDING MAY 8 1886

Kite, Isaac, Assistant Surgeon, ordered to Naval Hospital, Brooklyn

Simon, W J , P A Surgeon, ordered for temporary duty to the Naval Academy, Annapolis

Lippincott Geo C , P A Surgeon, ordered for temporary duty to the Naval Academy, Annapolis

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U S MARINE HOSPITAL SERVICE FOR THE WEEK ENDED MAY 1, 1886

Magruder, G M , Asst Surgeon, appointed an Asst Surgeon April 24, 1886 Assigned to temporary duty at Norfolk, Va , April 26, 1886

THE ADDRESS IN OBSTETRICS

HYSTERIA AND ITS RELATION TO DISEASES OF THE UTERINE APPENDAGES

Delivered at the Thirty-Seventh Annual Meeting of the American Medical Association on Tuesday, May 5, 1886,

BY S C GORDON, M D ,
OF PORTLAND ME
CHAIRMAN OF SECTION OF OBSTETRICS AND DISEASES OF WOMEN AND CHILDREN

MR PRESIDENT AND FELLOWS OF THE AMERICAN MEDICAL ASSOCIATION —The year that has just passed has given no remarkable discoveries either in obstetrics or gynecology, and therefore in attempting to comply with the rule requiring the chairman of each Section to present a *resume* of new things in his department, I can only emphasize some of the matters that have been alluded to, perhaps in some former addresses, and weigh the experiences of individual members of the profession on some of the topics that have been more or less discussed Time, which alone can give experience, makes sad havoc with many of our pet theories, however plausible they may seem when first advanced We are constantly exploding some of the well accepted doctrines of the old teachers in every department of medicine, and in none more than in these two branches of the science A familiar example of this occurred at the last meeting of this Association I think no one theory held stronger place among us than that an accoucheur, after exposure to septic influences, should for a long time refrain from attendance upon new cases A neglect of this rule was generally deemed criminal, and the penalty was visited upon the victim in the most severe and summary manner

The carefully prepared and exhaustive paper of Dr George F French, who collected opinions from the ablest men in the profession, from this country and Europe, together with his own critical experiments, shows us that by proper measures and strict, absolute cleanliness, we can safely continue the daily routine of obstetrical work, with no months of delay, or anxiety as to the results of such continuance The criminality now lies in the neglect of the proper precautions within the reach of every practitioner Time alone may not be sufficient—in fact, may be no element of safety, if all the other elements are omitted If the seed sown by that one paper has been properly cultivated and has borne the same kind of fruit, the harvest within the year just past must be abundant

I will not attempt to review the literature of obstetrics for the past year, so far as relates to new discoveries, or new methods of treatment of the parturient woman, but simply allude to some of the practical points which have been more or less *sub judice* for many years Among the many of these questions, the early signs of pregnancy may be mentioned I have several times within the past year applied the test recommended by Hegar and alluded to in several journals, viz the increase in the anterior curvature of the uterus, with increased elasticity of the walls I think it a valuable sign and one that is apparent early For obstinate vomiting of pregnancy, I believe no one measure has been found of such value as forcible dilatation of the cervical canal below the internal os, and lifting the uterus out of the pelvis and supporting by cotton packs or some form of pessary The cases requiring the induction of abortion for this very distressing symptom will, I think, be very few if these measures are faithfully and carefully carried out The induction of premature labor for deformity of pelvis or disproportionate head, as found by former pregnancies, is, I believe, fast finding favor with accoucheurs From my own experience (very limited) I prefer the employment of the bougie, retained until labor begins, although some practitioners whose opinion I value, prefer the rapid manual dilatation Where we fear a disproportionate head, I think the eighth month the best time for it, when a tolerable degree of certainty exists as to the period of conception

The post parturient management of the woman I think deserves much more consideration than it has formerly received I am sure that until within a comparatively short period authorities have been disposed to teach a much more rigid system of dietetics for the woman who has just passed through her labor than the absolute necessities of the case require I believe the "poor sloppy diet" of the lying in room has been a fruitful source of the "lingering delay" and complications of childbed Many a woman whose period of gestation has compelled her to forego all the pleasures of the table finds the demands of nature such that the most nutritious food is desired In my opinion we will find much benefit from a liberal construction of the rule that nature does not make mistakes often

A word or two in regard to ameliorating the sufferings and shortening the process of labor It seems that an unnecessary amount of suffering, both in degree and duration, attends the "normal labor" (so called) among the large majority of American women —that they do not, as a rule, bear children so easily as the women of the British Isles I am very well convinced—not only from statistics, but from the general sentiment so prevalent among British practitioners, that a forceps delivery is rarely required While it is not pertinent on this occasion to elaborate this very much—statistics being accessible and more or less familiar to all of you—I cannot but believe that the use of anæsthetics and the forceps, in labor, has done much to relieve the suffering and prevent many of the injuries formerly incident to the parturient process I believe that vesico vaginal fistulæ are becoming less frequent under the more careful and judicious use of the obstetric forceps, by means of which a long and tedious labor has been shortened, and the pressure has been removed from portions of the vagina that would otherwise have lost vitality and sloughed

The treatment of the placenta, both at normal labor and at abortion, has been the cause of much discussion for the past few years The views of Pajot, recently published, are so nearly in accord with my own experience and practice, that I cannot forbear alluding to them He believes that, as a rule, the full term placenta is best delivered by prompt and gentle traction upon the cord, with the left hand, while the right index finger passed up along the cord intelligently regulates the amount of force necessary to be used The earlier after the delivery of the child this is done, the more easily is it completed and less evil results follow

I believe also, with him, that the forcible removal of the secundines in abortions, at almost any cost (now so prevalent), is by no means the safer practice Remove them if it can be done without much trouble, or instrumental interference, but otherwise a careful tamponing and close watching will do less harm, save more lives and prevent a vast amount of future suffering

In passing to the subject of gynecology I propose to occupy your time principally with one theme, that has engaged the attention of the profession and promoted much discussion during the past year, viz the removal of the uterine appendages—familiarly and variously characterized as Battey's, Tait's and Hegar's operation

I am sure any practical work done in this direction will be regarded as testimony before a jury of the profession, and a basis for making a proper decision upon the merits or demerits of the operation The mere dictum of any one man or set of men amounts to but little in our profession Nothing is conclusive or convincing short of absolute experiment When a man, however distinguished he may be, says that he has never seen any case where, in his opinion, the operation was required, such opinion amounts to but little in comparison with another who has believed it was required, and demonstrated by the operation a well-marked pathological condition, and cured his patient, who has suffered for years

The profession has differed very widely as regards the indications for this surgical interference, some claiming that only by a "demonstration by touch" which shall determine absolute organic changes in the ovaries and tubes, should a diagnosis of disease be made On the other hand, others become satisfied of the existence of structural changes by certain manifestations, which we term functional disturbances, and are commonly called by the terms reflex and hysterical That a large class of cases exist in every community, that have been invalids for years, and have defied all methods of treatment, is a well known fact It is largely to this class that I call your attention, and shall therefore devote the remaining portion of the time allotted to me to the discussion of

HYSTERIA AND ITS RELATION TO DISEASES OF THE UTERINE APPENDAGES

I suppose it is equally true of medicine as everything else, that there is really "nothing new under the sun"—therefore we may as well select, as one of the topics for consideration, a well-worn subject for an essay on any medical occasion Certainly nothing has been talked about or written upon more than hysteria Even the laity are as familiar with the symptoms, pathology and treatment, as the (I might almost say) majority of the profession No literature of the profession in any age is complete, that does not embrace more or less learned discussions upon this ever fruitful subject

No one man from his own experience is able to fully represent in language the various and ever changing symptoms of this bane of the profession I am well aware that in presenting this subject before you a smile of derision may almost unconsciously come, and a degree of surprise be manifest at the presumption of one who would attempt to evolve anything that might be new or interesting out of such a threadbare theme And yet, when we find one of the modern writers on nervous diseases making the confession that "hysteria contributes absolutely nothing to the science of morbid anatomy," we are fully justified in advancing any theory that has a semblance of reason, especially if we can present any evidence that in the remotest degee will appear to sustain that theory The absolute in our profession may be very limited, but the probable is almost indefinite The sum total of medical science and knowledge rests upon the basis of this limited absolute and indefinite probable, the former having for its foundation principally anatomy and physiology, while the latter has the accumulated experiences, and observations, and experiments of thousands of educated students, through thousands of years To the mass of the practical minds of these students the latter is as valuable as the former When we find, after a series of experiments, that a constant result is reached by a continued course, we must finally admit that there is a relation of cause and effect By countless multitudes of practitioners it has been found that opium is the antidote to pain, that quinia is antipyretic and that chloroform is anæsthetic These and many other now well accepted facts in the profession came to us, not by any inductive reasoning, but by the more common mode of experiment and close observation Applying the latter method, together with what has come to us through the well known principles of physiology, to the disease known as hysteria, I believe we can at least make some little progress towards "contributing *something* to the science of morbid anatomy"

At the risk of being prosaic I must briefly allude to some of the more prominent symptoms of this classified disease I am quite sure I shall not challenge very much discussion on this point, even if I incorporate into my description nearly every symptom of human suffering known to medical science Their name is legion, I will use those necessary for the several illustrations Sydenham thus describes the multiform manifestations of hysteria "A day would scarcely suffice to reckon up all the symptoms of hysterical diseases, so various are they and so contrary to one another, that Proteus had no more shapes, nor the chameleon so great a variety of colors, and I think Democritus was pretty right (though he mistook the cause of the disease) when he wrote in an epistle to Hippocrates, that the womb was the cause of six hundred miseries, and of innumerable calamities Nor are they only very various, but also irregular, that they cannot be contained under any uniform type, which is usual in other diseases, for they are, as it were, a disorderly heap of phenomena, so that it is very hard to write the history of the disease" His only explanation of the fact that women have the disease so much more frequently than men, is that "kindly nature has bestowed on the former a more delicate and fine habit of body, having designed them for an easy life, and to perform the tender offices of love" His "confusion of spirits," too many of them "collected in a crowd," and that the "ataxy of the spirits has vitiated the humors," seem hardly a sufficiently lucid explanation of the etiology of the disease, in these modern days of exacting pathology, and yet it was nearly if not quite as satisfactory as any of the many theories of our later pathologists "It is nothing but an attack of hysterics," "she is only nervous," let her alone and she will come out of it all right," "isn't this hysterical largely?" "surely there cannot be any organic lesion," etc

Perhaps no better modern history of hysteria has been written than that of Hammond in his "Diseases of the Nervous System" In the first paragraph under the head of symptoms he says "The phenomena of hysteria may be manifested as regards the mind, sensibility, motility and visceral action, separately or in any possible combination Thus it is not uncommon to meet with cases in which the only evidence of the disease is seen in abnormal mental action, others are characterized solely by derangements of sensibility, such as hyperæsthesia or anæsthesia, others by aberrations of the faculty of motion, such as paralysis, spasms and contractions Again, all these categories may be witnessed in the same person, giving rise, among other phenomena, to coma and convulsions, and again, some one or more of the viscera may be deranged in their functions, and thus the appearance of organic disease be simulated"

These mental symptoms are so very various that any attempt to recite them would be a history of the whole class of mental diseases, from the slightest emotional disturbances to the most violent exhibitions of joy or grief, entirely disproportionate to the cause, to be followed, perhaps, by the utmost indifference to all surrounding influences That the will to a great extent loses its power, at times, no one familiar with these cases can for a moment doubt, although under the influence of some strong exciting cause, the patient suddenly acquires the lost volitional power Illusions and hallucinations of all kinds and degree occur in many of these cases, and we find most striking illustrations of the most complete aberrations of the special senses "Images are seen where there is nothing, voices are heard where there is absolute silence, odors are smelt where there is nothing to smell, and strange tastes are perceived where the mouth is empty" The vagaries of the intellect are not less strange than of the special senses The perceptive faculties are often most wonderfully sharpened, while the reasoning powers and volubility are remarkably increased As often we find the most brilliant intellects dulled and the conversational powers almost entirely wanting The principal points of difference between this and insanity seem to be the less duration of the phenomena and less power to influence the patient's actions

In the deranged sensibility we find all degrees of hyperæsthesia and anæsthesia, the most common seat being the skin, in the region of the mammary glands, face, throat, extremities, and especially about the head in the form of headache Hammond quotes Briguet as saying that "out of 356 hysterical patients 300 were constantly subject to headache" Neuralgia in all its manifestations, in all parts of the body, may thus exist, without our being able to give it a definite origin Anæsthesia, with a corresponding loss of feeling in all these parts of the body, may exist, and even the special senses be affected to the point of producing blindness, deafness, loss of taste and smell I have seen some very remarkable cases of blindness due to reflex disturbances of the genital organs, which were at once relieved by appropriate treatment of these lesions

Hysterical paralysis, as manifested in hemiplegia, paraplegia, or, much more limited than either, aphonia-spasms, tonic and clonic, may affect almost every muscle in the body, continuing a long time, and simulating organic lesions in muscles, joints and mucous membranes

The functional actions of the viscera are by far the most surprising manifestations of hysteria, and frequently the most persistent and distressing Of all these perhaps there is no one more commonly affected than the stomach Hammond says this seems to be the "favorite organ," and this is in accord with my own experience The most obstinate vomiting, persistent flatulency and all the various distressing symptoms of indigestion, characterize a majority of the cases under my own observation eral construction of the rule that nature does not make mistakes often

A word or two in regard to ameliorating the sufferings and shortening the process of labor It seems that an unnecessary amount of suffering, both in degree and duration, attends the "normal labor" (so called) among the large majority of American women —that they do not, as a rule, bear children so easily as the women of the British Isles I am very well convinced—not only from statistics, but from the general sentiment so prevalent among British practitioners, that a forceps delivery is rarely required While it is not pertinent on this occasion to elaborate this very much—statistics being accessible and more or less familiar to all of you—I cannot but believe that the use of anæsthetics and the forceps, in labor, has done much to relieve the suffering and prevent many of the injuries formerly incident to the parturient process I believe that vesico-vaginal fistulæ are becoming less frequent under the more careful and judicious use of the obstetric forceps, by means of which a long and tedious labor has been shortened, and the pressure has been removed from portions of the vagina that would otherwise have lost vitality and sloughed

"surely there cannot be any organic lesion," etc

Perhaps no better modern history of hysteria has been written than that of Hammond in his "Diseases of the Nervous System" In the first paragraph under the head of symptoms he says "The phenomena of hysteria may be manifested as regards the mind, sensibility, motility and visceral action, separately or in any possible combination Thus it is not uncommon to meet with cases in which the only evidence of the disease is seen in abnormal mental action, others are characterized solely by derangements of sensibility, such as hyperæsthesia or anæsthesia, others by aberrations of the faculty of motion, such as paralysis, spasms and contractions Again, all these categories may be witnessed in the same person, giving rise, among other phenomena, to coma and convulsions, and again, some one or more of the viscera may be deranged in their functions, and thus the appearance of organic disease be simulated"

These mental symptoms are so very various that any attempt to recite them would be a history of the whole class of mental diseases, from the slightest emotional disturbances to the most violent exhibitions of joy or grief, entirely disproportionate to the cause, to be followed, perhaps, by the utmost indifference to all surrounding influences That the will to a great extent loses its power, at times, no one familiar with these cases can for a moment doubt, although under the influence of some strong exciting cause, the patient suddenly acquires the lost volitional power Illusions and hallucinations of all kinds and degree occur in many of these cases, and we find most striking illustrations of the most complete aberrations of the special senses "Images are seen where there is nothing, voices are heard where there is absolute silence, odors are smelt where there is nothing to smell, and strange tastes are perceived where the mouth is empty" The vagaries of the intellect are not less strange than of the special senses The perceptive faculties are often most wonderfully sharpened, while the reasoning powers and volubility are remarkably increased As often we find the most brilliant intellects dulled and the conversational powers almost entirely wanting The principal points of difference between this and insanity seem to be the less duration of the phenomena and less power to influence the patient's actions

In the deranged sensibility we find all degrees of hyperæsthesia and anæsthesia, the most common seat being the skin, in the region of the mammary glands, face, throat, extremities, and especially about the head in the form of headache Hammond quotes Briguet as saying that "out of 356 hysterical patients 300 were constantly subject to headache" Neuralgia in all its manifestations, in all parts of the body, may thus exist, without our being able to give it a definite origin Anæsthesia, with a corresponding loss of feeling in all these parts of the body, may exist, and even the special senses be affected to the point of producing blindness, deafness, loss of taste and smell I have seen some very remarkable cases of blindness due to reflex disturbances of the genital organs, which were at once relieved by appropriate treatment of these lesions

Hysterical paralysis, as manifested in hemiplegia, paraplegia, or, much more limited than either, aphonia-spasms, tonic and clonic, may affect almost every muscle in the body, continuing a long time, and simulating organic lesions in muscles, joints and mucous membranes

The functional actions of the viscera are by far the most surprising manifestations of hysteria, and frequently the most persistent and distressing Of all these perhaps there is no one more commonly affected than the stomach Hammond says this seems to be the "favorite organ," and this is in accord with my own experience The most obstinate vomiting, persistent flatulency and all the various distressing symptoms of indigestion, characterize a majority of the cases under my own observation

The disturbances of function of other organs, like the heart, lungs, intestines, kidneys (with their inordinate secretion of limpid urine), the bladder with retention and incontinence of urine, the obstinate constipation of the bowels, are all familiar to every practitioner The various forms of convulsions, attended with more or less loss of consciousness, bearing oftentimes a strong resemblance to epilepsy or tetanus, chorea or catalepsy, but distinguished from them by lack of consistency and constitutional disturbance, become the most distressing to witness and the most exhausting in their effects upon the nervous system

The functions of the uterus suffer in every conceivable manner, from complete cessation of the menstrual flow for months at a time, alternating with the most frequent hæmorrhages, either very scanty (lasting but a few hours), or the most alarming in quantity The pain and general nervous symptoms, as a rule, are most marked previous to the flow, oftentimes for many days, and these are so severe as to indicate with certainty the approach of the period even if the patient had no other definite means of knowing it I think this an important diagnostic element More rarely we find the exhaustion consequent upon the excessive hæmorrhages produces the well known hysterical convulsions, so familiar to every practitioner The week preceding and following the flow (including it) is the time during which we may expect, and in fact find the most of these nervous phenomena In many cases the remainder of the month may be comparatively free from any suffering whatever, especially in early life As age advances, however, the periodical suffering leaves its impress upon the entire system Not infrequently we find, as a result of the long continued nervous symptoms, marked changes in the facial expression, and a dull, listless melancholy rests upon a countenance once bright, animated and cheerful The skin suffers especially, in many instances Eruptions of various kinds, especially acne, appear, often to a degree that is disfiguring and loathsome to the patient Alternations of color occur, so that in a few hours we find the most ghastly pallor, followed by a deep mahogany color, which may and in many instances does continue for several hours In several cases under my own observation this latter symptom has been very marked, so that I now look upon it as a prominent diagnostic feature

But enough has been said on the symptoms, and we pass to the etiology Having already given you Sydenham's views on this point, I will add that of a more modern author and then give you some cases from my own experience, and there leave the subject

All authorities agree upon one predisposing cause,
as by far the most impo [illegible] —so important and pre-
dominating that, in my o [illegible] , it becomes very highly
significant, viz sex [illegible] omparatively
short time hysteria in th [illegible] en talked
or written about, and eve [illegible] we know
of the reported cases, th [illegible] cter by
comparison Men have [illegible] nd it
would be wonderfully str [illegible]
times f [illegible] manifestations o

closely correspond with one or more of the multiform phases of what we have just described Hammond says that in "332 cases observed by him in six years, 329 were females" Now it is not the object of this paper to attempt to enter into all the causes that have produced and may continue to produce hysteria in the female The causes may be as various as the symptoms or the cases—I do not deny any cause that may seem to be well established by any mode of reasoning, whether derived from theory or practice I simply propose to give you some instances derived from my own experience, selecting such cases, from quite a large number treated, as will illustrate a variety of symptoms, and results obtained by the methods employed

Case 1—Miss B, age 37, occupation a school teacher for many years A woman of unusually fine culture and strong character in all respects Had been particular successful in her vocation Possesing an indomitable will, she had continued in her work as long as possible, but for about five years previous to coming under my care, had been unable to do any labor, either in teaching or otherwise Her illness dates from eleven years before During the first few years she suffered from impairment of menstrual function, alternating amenorrhœa and menorrhagia, severe dysmenorrhœa, with marked premenstrual pain for many days Gradually the nervous symptoms became more prominent, characterized by insomnia, headaches, neuralgia in spine and sides, flushing and pallor of face, the dark red spot in the centre of each cheek becoming a prominent symptom in the later years She had consulted physicians early in her trouble, but only at rare intervals, and for five years previous to my seeing her, had been constantly under the care of the best she could obtain Notwithstanding she continued to grow worse until she became a helpless invalid, unable to work physically or mentally, or even to move about The mind became disordered to the extent that her friends proposed removing her to an insane asylum

When I saw her she could get around her room and out of doors by holding on to the sides of the room and thus supporting herself, but her limbs seemed to have lost their use so far as supporting the body She slept but little, and could not restrain herself from long attacks of crying I think she had a strong suicidal tendency As each menstrual period approached the symptoms were all aggravated, and during the period she was apparently oblivious of much that occurred Knowing that she had received as good care and treatment as the State afforded, with apparently no relief, I soon became convinced that nothing but a cessation of the menstrual function offered much hope I found sharp retro flexion of the uterus, to which pessaries gave no relief, on account of the extreme sensitive condition of the vagina, preventing her wearing one for any length of time There was also prolapsus of the right ovary, so that it could be felt in the posterior cul de sac It was not particularly tender, however, and was movable and easily pushed up, so I did not attach special importance to the fact of displacement alone Where no pressure exists in these cases, I think we are not to regard it of so much consequence as it was formerly supposed to be

On June 20, 1883, I removed the uterine appendages I found very extensive cystic degeneration of each ovary, the right one being about twice the size The tubes were partially closed, and had several small cysts adherent to them There was a general passive congestion of all the parts removed It was impossible to retain the uterus in place, so the retroflexion continued, and I doubt not retarded the progress of recovery, which from that time commenced, and slowly, but surely, continued, growing better each month All the prominent hysterical symptoms had disappeared at the end of the first year, and she began to enjoy the comfort of life On the anniversary of the day of her operation, at the end of two years she writes as follows

' Please permit me once more an expression of gratitude for the gain of these last two years I can see that I am *stronger* than a year ago, and *much improved* from two years ago I thank you very much and can always assure you of my best wishes " Within the past year she has grown still better In many respects this was one of the very bad cases on account of the severe and obstinate retro flexion

Case 2 —Miss B , aged 24 From her first menstrual period until the day of operation, she suffered the most terrible agony sixteen days out of every twenty eight Twelve of these days of suffering were marked by epileptiform convulsions, pain of the most excruciating character in all parts of the body, the following four days had no less suffering, but were attended with flowing The remaining twelve days of the month were almost entirely free from suffering of any kind whatever, but always at the end began the same round of troubles Her friends became very anxious in regard to her as she frequently threatened to take her own life In this case there was partial prolapse of one ovary

The operation for removal of tubes and ovaries was made, and the specimens showed a condition similar to the last, with the addition of a complete string of small cysts along the entire length of one of the fallopian tubes They looked like a string of small beads There was complete closure of both tubes From that day until now, she has not had (to use her own language) "one minute of any kind of ache or pain," she is perfectly well in all respects and the most grateful and happy person one would rarely meet, with no hysteria or other abnormal nervous symptoms

Case 3 —Miss F , aged 17 Menstruation began at 15, from the first time to the last of a most violent character, both as to pain and quantity of flow—frequently flooding like a woman at childbirth—clots of immense size, and expelled with characteristic laborpains For several months prior to operation, she was not free from severe pain at all Clonic spasms of a most frightful kind in lower extremities, necessitating the constant use of chloroform by inhalation for days together The uterus normal in all respects —no fungus degeneration or evidence of unusual congestion—a curetting under ether revealed nothing abnormal—no enlargement of ovaries or tubes could be demonstrated Everything in way of treatment was resorted to for a year without the slightest relief being obtained The appendages of the uterus were removed, and each ovary was found so completely destroyed by inflammatory action and cystic degeneration that, as my notes have it, "scarcely any normal tissue left in either,"—" tubes closed and cysts along the course of them "

For four weeks she suffered no pain at all, scarcely requiring an opiate, at the end of that time she got out of bed herself, sat up nearly all day, got pelvic cellulitis, from which she suffered more or less for several months, which ended in abscess opening through the uterus into the vagina From that time she began to recover, and is now as well apparently as any one There was never any return of the spasms or general neuralgia, so constant before the operation From a helpless, hopeless victim of terrible suffering, she is now a comfortable, useful young lady In this case there was an entire absence of any of the usual developments at the period of puberty —no enlargements of the breasts—no hair at all on the mons veneris, or external genitals I think the unsexing in this case could not have been very much

Cases 4 and 5—So closely resemble each other, and being of another type from those described, I give them together Miss L and Miss N , of about the same age, 24 Miss L , temperament, family and personal, nervous Four sisters—all nervous—three have painful menstruation Menstruated first at 13 —not regular first year—nausea, pain in back, headache and pain in the lower limbs, length of period five or six days Had measles four and a half years before the operation, since which has been suffering much at periods—flow of but one day—within the past two and a half years the flow has been followed by nausea and vomiting nearly every morning for two weeks Hysterical symptoms of a painful convulsive character at each period—screaming, crying, globus, etc Never had hysteria before measles Has been under the best medical care she could obtain, with all the opportunities of best hospital care—no relief whatever I found a very sharp antiflection at cervico corporeal junction—made forcible dilatation, followed by the usual local treatment of packs, douches, rest, etc , no relief Operation showed extensive follicular cystic degeneration of both ovaries, with atheromatous closure of tubes

Miss N so closely resembled the last, both in having measles as a cause of aggravation of symptoms and antiflexion, that a history of one is that of the other in many respects The flow was preceded by many days of severe suffering, which became hysterical convulsions during the flow, which lasted two weeks The character of pain and amount of flow, at each period, resembled a miscarriage of the severest kind, dilatation afforded no relief, no fungus growth that could account for flooding After several years of treatment with no benefit, the operation of removal of uterine appendages was made with entire relief to all suffering From being a chronic invalid she is now entirely well and able to perform

The disturbances of function of other organs, like the heart, lungs, intestines, kidneys (with their inordinate secretion of limpid urine), the bladder with retention and incontinence of urine, the obstinate constipation of the bowels, are all familiar to every practitioner The various forms of convulsions, attended with more or less loss of consciousness, bearing oftentimes a strong resemblance to epilepsy or tetanus, chorea or catalepsy, but distinguished from them by lack of consistency and constitutional disturbance, become the most distressing to witness and the most exhausting in their effects upon the nervous system

The functions of the uterus suffer in every conceivable manner, from complete cessation of the menstrual flow for months at a time, alternating with the most frequent hæmorrhages, either very scanty (lasting but a few hours), or the most alarming in quantity The pain and general nervous symptoms, as a rule, are most marked previous to the flow, oftentimes for many days, and these are so severe as to indicate with certainty the approach of the period even if the patient had no other definite means of knowing it I think this an important diagnostic element More rarely we find the exhaustion consequent upon the excessive hæmorrhages produces the well known hysterical convulsions, so familiar to every practitioner The week preceding and following the flow (including it) is the time during which we may expect, and in fact find the most of these nervous phenomena In many cases the remainder of the month may be comparatively free from any suffering whatever, especially in early life As age advances, however, the periodical suffering leaves its impress upon the entire system Not infrequently we find, as a result of the long continued nervous symptoms, marked changes in the facial expression, and a dull, listless melancholy rests upon a countenance once bright, animated and cheerful The skin suffers especially, in many instances Eruptions of various kinds, especially acne, appear, often to a degree that is disfiguring and loathsome to the patient Alternations of color occur, so that in a few hours we find the most ghastly pallor, followed by a deep mahogany color, which may and in many instances does continue for several hours In several cases under my own observation this latter symptom has been very marked, so that I now look upon it as a prominent diagnostic feature

But enough has been said on the symptoms, and we pass to the etiology Having already given you Sydenham's views on this point, I will add that of a more modern author and then give you some cases from my own experience, and there leave the subject

All authorities agree upon one predisposing cause, as by far the most important—so important and predominating that, in my opinion, it becomes very highly significant, viz sex Until within a comparatively short time hysteria in the male was not even talked or written about, and even accepting all that we know of the reported cases, they are trivial in character by comparison Men have a nervous system, and it would be wonderfully strange if we did not sometimes find manifestations of disease that would very closely correspond with one or more of the multiform phases of what we have just described Hammond says that in "332 cases observed by him in six years, 329 were females" Now it is not the object of this paper to attempt to enter into all the causes that have produced and may continue to produce hysteria in the female The causes may be as various as the symptoms or the cases—I do not deny any cause that may seem to be well established by any mode of reasoning, whether derived from theory or practice I simply propose to give you some instances derived from my own experience, selecting such cases, from quite a large number treated, as will illustrate a variety of symptoms, and results obtained by the methods employed

Case 1—Miss B, age 37, occupation a school teacher for many years A woman of unusually fine culture and strong character in all respects Had been particular successful in her vocation Possesing an indomitable will, she had continued in her work as long as possible, but for about five years previous to coming under my care, had been unable to do any labor, either in teaching or otherwise Her illness dates from eleven years before During the first few years she suffered from impairment of menstrual function, alternating amenorrhœa and menorrhagia, severe dysmenorrhœa, with marked premenstrual pain for many days Gradually the nervous symptoms became more prominent, characterized by insomnia, headaches, neuralgia in spine and sides, flushing and pallor of face, the dark-red spot in the centre of each cheek becoming a prominent symptom in the later years She had consulted physicians early in her trouble, but only at rare intervals, and for five years previous to my seeing her, had been constantly under the care of the best she could obtain Notwithstanding she continued to grow worse until she became a helpless invalid, unable to work physically or mentally, or even to move about The mind became disordered to the extent that her friends proposed removing her to an insane asylum

When I saw her she could get around her room and out of doors by holding on to the sides of the room and thus supporting herself, but her limbs seemed to have lost their use so far as supporting the body She slept but little, and could not restrain herself from long attacks of crying I think she had a strong suicidal tendency As each menstrual period approached the symptoms were all aggravated, and during the period she was apparently oblivious of much that occurred Knowing that she had received as good care and treatment as the State afforded, with apparently no relief, I soon became convinced that nothing but a cessation of the menstrual function offered much hope I found sharp retro flexion of the uterus, to which pessaries gave no relief, on account of the extreme sensitive condition of the vagina, preventing her wearing one for any length of time There was also prolapsus of the right ovary, so that it could be felt in the posterior cul de sac It was not particularly tender, however, and was movable and easily pushed up, so I did not attach special importance to the fact of displacement alone Where no pressure exists in these cases, I think we are not to regard it of so much consequence as it was formerly supposed to be

The operation for removal of tubes and ovaries was made, and the specimens showed a condition similar to the last, with the addition of a complete string of small cysts along the entire length of one of the fallopian tubes They looked like a string of small beads There was complete closure of both tubes From that day until now, she has not had (to use her own language) "one minute of any kind of ache or pain," she is perfectly well in all respects and the most grateful and happy person one would rarely meet, with no hysteria or other abnormal nervous symptoms

Case 3—Miss F, aged 17 Menstruation began at 15, from the first time to the last of a most violent character, both as to pain and quantity of flow—frequently flooding like a woman at childbirth—clots of immense size, and expelled with characteristic laborpains For several months prior to operation, she was not free from severe pain at all Clonic spasms of a most frightful kind in lower extremities, necessitating the constant use of chloroform by inhalation for days together The uterus normal in all respects—no fungus degeneration or evidence of unusual congestion—a curetting under ether revealed nothing abnormal—no enlargement of ovaries or tubes could be demonstrated Everything in way of treatment was resorted to for a year without the slightest relief being obtained The appendages of the uterus were removed, and each ovary was found so completely destroyed by inflammatory action and cystic degeneration that, as my notes have it, "scarcely any normal tissue left in either,"—"tubes closed and cysts along the course of them"

For four weeks she suffered no pain at all, scarcely requiring an opiate, at the end of that time she got out of bed herself, sat up nearly all day, got pelvic cellulitis, from which she suffered more or less for several months, which ended in abscess opening through the uterus into the vagina From that time she began to recover, and is now as well apparently as any one There was never any return of the spasms or general neuralgia, so constant before the operation From a helpless, hopeless victim of terrible suffering, she is now a comfortable, useful young lady In this case there was an entire absence of any of the usual developments at the period of puberty—no enlargements of the breasts—no hair at all on the mons veneris, or external genitals I think the unsexing in this case could not have been very much

Cases 4 and 5—So closely resemble each other, and being of another type from those described, I give them together Miss L and Miss N, of about the same age, 24 Miss L, temperament, family and personal, nervous Four sisters—all nervous—three have painful menstruation Menstruated first at 13—not regular first year—nausea, pain in back, headache and pain in the lower limbs, length of period five or six days Had measles four and a half years before the operation, since which has been suffering much at periods—flow of but one day—within the past two and a half years the flow has been followed by nausea and vomiting nearly every morning for two weeks Hysterical symptoms of a painful convulsive character at each period—screaming, crying, globus, etc Never had hysteria before measles Has been under the best medical care she could obtain, with all the opportunities of best hospital care—no relief whatever I found a very sharp antiflection at cervico corporeal junction—made forcible dilatation, followed by the usual local treatment of packs, douches, rest, etc, no relief Operation showed extensive follicular cystic degeneration of both ovaries, with atheromatous closure of tubes

Miss N so closely resembled the last, both in having measles as a cause of aggravation of symptoms and antiflexion, that a history of one is that of the other in many respects The flow was preceded by many days of severe suffering, which became hysterical convulsions during the flow, which lasted two weeks The character of pain and amount of flow, at each period, resembled a miscarriage of the severest kind, dilatation afforded no relief, no fungus growth that could account for flooding After several years of treatment with no benefit, the operation of removal of uterine appendages was made with entire relief to all suffering From being a chronic invalid she is now entirely well and able to perform any kind of labor Miss L was also completely relieved from suffering, but has not yet regained her strength so as to be able to be about, although she is improving rapidly, considering her very anæmic condition previous to operation

The pathological condition of the tubes and ovaries were similar in Miss N 's case, except that there were two or three cysts of the tubes as large as peas

Case 6 —Mrs F , age 30, married seven years, had three children within four years, never pregnant after that, although no means were used to prevent it Three years ago began to have nausea and vomiting, which in six months became a constant thing after taking food She and her husband believe that for the two years previous to operation she did not retain a spoonful of any kind of food She became almost entirely bloodless, and so weak that she would frequently fall to the floor, when about her work, in a hysterical convulsion, that would sometimes last for hours Symptoms aggravated before and during menstrual period

After two years of treatment under my care I became convinced that only a cessation of menstruation would give relief For a few months she tried various modes of treatment, and finally consented to the operation In three weeks she was able to return to her home From the day of the operation she did not vomit once, but was able to eat everything she desired Previous to the operation her finger nails had become entirely dead, flattened, clubbed and turned up at the ends, so as to cause the ends of the fingers to bleed and be constantly painful Since the operation everything has changed she is a strong, florid, fine healthy woman as the city affords taking entire charge of her family and riding on horseback and driving every day The left ovary was twice the normal size and contained a cyst holding half a drachm

A similar case to the last, so far as the constant vomiting is concerned, I operated upon two months since, and so far as we are able to judge at this time the result is equally good Married sixteen years, a great sufferer from dysmenorrhœa fourteen years, during which time she has been under good treatment from various intelligent physicians, never pregnant Alternations of amenorrhœa and severe flooding, with repeated attacks of pelvic peritonitis Tubes and ovaries adherent throughout their entire length I had great difficulty in detaching them, but finally succeeded The ovarian tissue was entirely destroyed by inflammatory softening and exudate, tubes impervious and like whipcord, a chronic partial congestion in all the pelvic organs Severe and obstinate vomiting followed operation for more than two weeks, accompanied and doubtless largely caused by peritonitis Now she is taking a good quantity of nourishing food with impunity, and is recovering very rapidly

I have selected these two together, as they illustrate one phase of the reflex symptoms

In another case Miss L , aged about 30, hysterical catalepsy had been a marked symptom for several years She would lie for weeks at a time utterly oblivious of everything and every one about her At intervals rigidity of body would come on, lasting for hours Neither drugs or other means of treatment gave any relief She had all the benefit of hospital care and attention for months at a time There was marked retroflexion with complete retroversion Replacement and support would relieve for a short time, but nothing permanent came until the operation of castration was made, since which she has never had the slightest return of any one of the symptoms Extensive follicular degeneration of ovaries was found Insomnia, vomiting and indigestion had been prominent in this case She eats, sleeps and digests perfectly, and is now a healthy, well nourished young lady

I have not time, even had I the courage, to trespass upon your patience to report any more cases I have now made the operation twenty-five times, and each case has a certain amount of professional interest Four or five have been made for uterine fibroids, mostly for excessive hæmorrhage, with complete relief to the hæmorrhage One case the removal was made hoping it might stop the growth of a fibroid and relieve the suffering due to pressure There has been no relief, however I think cases like this should have hysterectomy The cases reported were selected as types of the various phases of hysteria Among the cases not reported are types of the same phases, and with as good results

In only one instance I was unable to remove the entire substance of the ovary and tube, and this is the only instance of continued menstruation She suffers very much at these periods, and I think I shall make another trial to finish it In no case have I failed to find well marked disease of the appendages, either strong evidences of former attacks of oophoritis, as indicated by exudate and other organic changes in the substance of the ovary, or enlargement and stenosis of the fallopian tube In not more than four instances have I been able to make a diagnosis by the touch, but have in all the others operated entirely for the relief of the hysterical symptoms With the single exception named, in every case great relief has followed, and with two exceptions, I have no reasonable doubt that a complete cure will result after a reasonable length of time We cannot expect that a nervous system that has suffered for years will at once resume its normal functions The wound is tender after the thorn has been removed Effects do not immediately cease on removal of the cause, women suffer more or less from some disorders of the nervous system at the natural menopause, similar symptoms naturally follow an artificial one

I do not by any means claim that all hysterical symptoms are due to diseased uterine appendages, but I am sure, from this experience, that in these cases they stand in the relation of cause and effect I know that in a very large majority of these cases these women have been suffering invalids for years, and that all modes of treatment have been of no avail From being burdens to themselves, and dependent upon their friends for help, they are now comfortable and independent Through long suffering and in many instances from lack of sympathy for their suffering, life has lost its charm and they would gladly have rid themselves of it, while now they are glad to take their places as useful members of society

I have never operated in any case where I have not been well satisfied, either from my own care of the case, or from that of intelligent physicians, that further treatment in any other manner would be of no avail I have no regrets at the course pursued up to the present time, and I know of no case where the patient regrets the step she took

In answer to the objection that it unsexes the woman, I have only to say that in all the married wo men, they either have never been pregnant or have not since the beginning of their most serious symptoms, even though several years have elapsed since their last childbirth

Dr W Gill Wylie, professor of gynecology in the New York Polyclinic, in reporting thirty seven operations for removal of the uterine appendages, in the *Medical News* of March 27, 1886, says "I have yet to see a well-marked case of hystero-epilepsy or decided hysteria operated upon, in which the ovaries were not found in a state of cystic degeneration or very much atrophied And these are nearly always associated with an imperfectly developed or atrophied uterus " And in the same paper he says, what I have found true in several cases, "that in those cases where the subjective symptoms were chiefly reflex and of a nervous order, the *immediate* results were by no means always satisfactory, although many recovered after being seemingly unimproved for several months "

When we take into account how little has formerly been done in these long-standing reproaches to the profession, we can certainly get much comfort from the results in his cases On this point he says "It is yet too soon to speak positively about the results of the operation in all classes of cases, but I can say without hesitation that in those cases where the subjective symptoms were actual local pain and physical inability to go about without causing persistent pain —and almost all the cases of pyo-salpinx would come under this head—the results were good and satisfactory to the patient and physician In many cases the relief from pain was gratefully acknowledged at once "

This is so thoroughly in accord with my own experience that I need only to quote it as applicable in a majority of my own cases The experience of Battey and Tait, who are deservedly the pioneers in this department of gynecology, is now so well known to the profession, that it would be supererogation at this time to allude to it in detail It is no longer a question with them what shall be done with this large class of sufferers, by hundreds of cases they have demonstrated the utility of the procedure

The very extensive and valuable papers relating to to this and kindred subjects, by Mary Putnam Jacoby, show that what at first glance may seem to be only slight changes in the ovary and tubes, are really severe structural organic changes, that without doubt have destroyed their function

If I were asked to formulate my views, derived from my own experience and that of the men who have done much more in this direction, I should sum up about as follows

1 That these (so called) hysterical symptoms occur almost exclusively in women That whenever any of them do occur in men they are much less in degree, even if they do not differ in kind

2 That it is fair to presume from the first proposition that it is due to disease of some organ or organs peculiar to women

3 That they are not due to disease of the uterus alone, for when all apparent abnormalities of the uterus are corrected, the symptoms, very often, are not in the least relieved

4 That all modes of treatment, other than operation, have failed to cure, and in most instances have not ameliorated, the symptoms, even where the disease was believed to exist in the uterine appendages

5 That the large majority of all cases operated upon have been entirely cured of the symptoms for which the operation was made, and the remnant have been relieved and are continuing to improve

6 That it is impossible, in a majority of cases, to determine by the touch, disease of these organs that will produce the symptoms alluded to

7 That one can by these symptoms alone make a sufficiently satisfactory diagnosis to warrant the operation

8 That after correction of all well known and clearly diagnosticated uterine troubles, these symptoms are not relieved, we are justified and required, for the cure of our patient, to recommend this remedy

9 That the operation does not in any case destroy the sexual desire, or in any way unsex the woman, except so far as it may prevent further childbearing

10 That in a majority of cases requiring the operation the woman is already sterile

11 That in my own experience the specimens removed have been found so changed by inflammatory action as to be cirrhotic, or otherwise destroyed, either by softening or cystic degeneration of both ovaries and tubes, with very frequent stenosis of the latter

12 That a fatal result from the operation is extremely rare, if it is carefully performed and closely and intelligently managed as to the after treatment In the twenty-five cases operated upon there has been but one death

It is certainly time that the profession were done with the old idea that a hysterical woman is only to be laughed at, and treated as one who deserves no consideration at our hands Thousands of women, of the strongest character, have been cruelly and shamefully treated by their friends, even while they were suffering the most excruciating agony, and simply because the profession has given countenance to the theory that "she could prevent it if she chose," that she was "only hysterical " We cannot expect more from the laity than we teach them Instead, let us each strive to "contribute something to the science of pathological anatomy" out of this mass of distressing symptoms

THE DANGERS OF KISSING[1]

BY SAMUEL S ADAMS, A M , M D

PROFESSOR OF THE THEORY AND PRACTICE OF MEDICINE, MEDICAL DE PARTMENT OF THE NATIONAL UNIVERSITY ONE OF THE ASST ATTENDING PHYSICIANS CHILDREN S HOSPITAL D C ETC

For more than two years past I have had in mind the preparation of this paper, and much of the material has been collected during that period I have only recently, however, examined the literature of the subject, and was greatly surprised to find it so meagre None of the ideas advanced in this article have been borrowed from this literature, as they were conceived before this was examined, but I do not claim that they are specially new, however original they may be

My first purpose was to discuss the subject from a purely professional standpoint In a late number of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION[2] the editor commented on "Compulsory Kissing," basing his remarks upon an article from the pen of Eleanor Kirk,[3] in which she undertakes to defend the parent who has the courage to oppose this reprehensible habit After reading these two papers I determined to broaden the scope of this communication and cast it in a mould more for the general reader than is consistent with a purely professional audience

As I said before, I was surprised at the meagreness of the professional literature upon this subject There may be isolated reports of cases of diseases transmitted by kissing which I have not found, but the library of the Surgeon General U S Army contains only two works bearing on the subject, both of which were published in the early part of the eighteenth century

These are in the Latin, and I am indebted to my friend, Dr Kolipinski, for valuable assistance rendered in their translation From the following brief abstracts may be gathered the general drift of these writers, and I also add one or two notes from others who have mentioned the fact of a disease being communicated by kissing

Ermelius[4] says that reason and experience prove that the saliva is especially calculated to be a carrier of the contagium The "molecules" (poisonous germs) are hidden under its viscidity It may contain a great number of "*aireo ætherial particles*" of a benign or malignant nature, as hydrophobia

Forestus[5] has shown that kissing has been the source of contagion in syphilis

Hentschel[6] contends that the "*miasms*" of various diseases can be carried with kisses—scorbutic, venereal, purpuric, petechial, scabious, leprous, pestilential, and all other species of contagion in which the causes are subtile Not only the volatile substances which may be conveyed to others in respiration, but also the saliva and the vapor and exhalations of the mouth may be transmitters Therefore, ulcerous infection salivary tumors, cancrum oris, scurvy, syphilis and phthisis may likewise be communicated

Paullini[1] bewails the transmission of scurvy among German children by kissing as a salutation, a custom of England, Holland and France

Oertel reports two cases of diphtheria contracted by a kiss, the membrane appearing on the second day

Kissing is a custom that not only prevails universally among the human race but also in some of the lower animals There is a vast difference, however, in the exercise of this custom In the former the kiss is given to almost any submissive person, while in the latter it is only employed as one of the means of expressing affection The truth of this latter proposition is well illustrated in the bird which will frisk among its playmates without being tempted by their charms to give up the kiss which is reserved for its mate alone It may be said that the animal looks about, finds its mate, bestows its kisses, propagates, raises its offspring and, finally, divorces itself, thereby gaining numerous mates, but we know that many animals, if undisturbed, will continue with the same mate and raise successive broods, and will not seek a new one each season There is this difference between the animal and the man the one mates before it kisses, the other kisses before he mates

Reasoning from analogy the conclusion that kissing was originally intended to give utterance to the affection is reasonable How far this intention has been perverted by man is a problem not easily solved, and yet the solution would seem easy if one were allowed to reason from the promiscuous and broadcast kissing of every day life Instead of being an expression of one of the noblest attributes of man, it has almost degenerated into an insincere, unmeaning and common-place salutation

When kissing is confined to the same sex there is a great difference in its sincerity In some European countries the custom is for men to kiss one another on the forehead or cheek but in this country the practice prevails only to a very limited extent, and only then as an expression of the warm affections between father and son or brother and brother

Between females the act has become so common that it is hardly more than a ready and easy mode of greeting, having no greater meaning than the conventional hand shaking

When kissing is extended to the opposite sex I must accord to woman the credit of being the more cautious upon whom this index of devotion is bestowed

All this simply shows that kissing is extensively and injudiciously practiced by those who have arrived at the years of discretion, thereby setting a bad example for those of less mature judgment There can be no question that certain transmissible diseases are communicated by promiscuous kissing among adults, and it is fair to assume that the same diseases are communicated to children in the same way Adults are supposed to be capable of judging for themselves in such matters and it would be folly in me to attempt

to restrict them in exercising these privileges, but as they are the guardians of the children this paper will be devoted to pointing out to them some of the dangers to infants and children of promiscuous kissing, and the suggestion of a few remedies for its suppression.

From birth to the beginning of sexual evolution, perhaps, the child is exposed to moral, mental and physical dangers from promiscuous kissing. Up to the latter age kissing is not a matter of choice, but an act made compulsory by the kisser or by someone having the supervision of the child. Indeed the infant is the passive victim, and it is not until the third or fourth year that the child repels the aggression. Then, it too frequently happens that in spite of its disinclination, it is forcibly compelled to submit. With increased strength comes a growing aversion to kissing, coincident with the rapid growth and physiological development of childhood, which seems to be one of the many wise provisions of nature for protecting the delicately constructed and rapidly changing organism from the numerous extraneous causes of disease.

It would be interesting to follow a baby from the time it is placed in its perambulator and receives the maternal kiss until it returns later in the day, in order to note the peculiarities, both mental and physical, of the numerous persons who stop to kiss it. To gain some idea of the mixture and the probabilities of the transmission of disease one need only sit in one of our large parks on a bright sunny morning and study the physiognomies of the strangers who kiss the baby as it lies in its carriage. At this time there are not unlikely a dozen maids with as many or more infants and young children congregated there. These custodians extend the matutinal salutation by kissing the babies all round. Among a dozen such people it is not improbable that some benign or malignant disease may be found. In a former contribution[1] I pointed out the difficulty in selecting wet-nurses and the danger to the infant in being wet nursed. I then claimed that we could not vouch for the health of any woman because of the latency of many diseases. With equal weight, I believe, the same argument may be advanced respecting the selection of nurse maids. Mothers are afraid certain transmissible blood diseases may be conveyed to the child through the wet-nurse's milk, and they want their family physician to assume the responsibility of her selection. It may not have occurred to these watchful mothers that the same blood diseases can be conveyed by other liquids of the body, and this, perhaps, may account for the absence of the doctor's advice in choosing the maid.

If it be true that tuberculosis is due to specific germs which pervade every portion of the body and circulate in every fluid, then the child's chances of being inoculated by the saliva, in kissing, are as great as by the milk in nursing. So impressed am I with this mode of inoculation, that I usually inquire into the maid's history whenever I am called upon to treat an eruptive disease of doubtful character in a child.

Not long since I observed, lying in a carriage, a beautiful baby which indicated every evidence of wealth and high social standing. Pushing this vehicle was a girl whose facies bore evidence of the secondary symptoms of syphilis. Would it have been surprising if the virus had been transferred by a kiss to this child? On the contrary, it will be marvelous if it escape. The merest tyro in medicine would assume the responsibility of discharging such a maid.

Some time ago a fellow practitioner reported the case of an estimable young lady who had a chancre on her lip. Admission confirmed the opinion of her physician that the man to whom she was betrothed had contracted the disease and, unfortunately, had inoculated her lips in kissing her. Suppose this man had kissed one or more of this dozen babies—a thing not at all improbable—and they had caught the disease? The result might have been the same, but would the source of contagion have been as easily discovered?

Mechanical injuries may also be caused by kissing. When it is remembered how delicate the infantile structures are, the wonder is that they so often escape injury. May not some of the misshapen mouths and distorted features be traced to too much kissing? One need only reflect upon the powerful suction sometimes displayed in such performances to realize its dangers. There is a well authenticated case in which the membrana tympani was ruptured by kissing the external opening of the ear, undoubtedly due to suction, and I have seen an ecchymotic spot on a child's cheek caused by prolonged suction in kissing it. Although I have not seen any injury to the eye positively traceable to this cause, nevertheless, in my opinion, its delicate structures could easily be injured in this manner.

These perpetual baby kissers are not particular where they ply their vocation. The mouth and face are the sites most frequently selected, but other parts of the infantile anatomy seem to answer the purpose equally as well.

But aside from these physical injuries, there are moral ones as well in childhood. At this time of life the disposition of the child is being formed, and it should be the aim of every parent to train it so as to be gentle and kindly. As the child grows older kissing perhaps becomes obnoxious to it, yet some parents there are who will force it to submit to the distasteful ordeal even to the point of inflicting corporal punishment for refusal. How many of my readers can recall those happy juvenile days that were made miserable by punishments inflicted because they refused to be kissed by some repulsive visitor. Who of us but can revert to those moments of torture when we were called from our games to be kissed? I venture to say that many of my readers have undergone the child's experience, and have run at the sight of a visitor because remaining meant kissing. Were you punished for escaping? If so, do you still wonder that when children are forced to these distasteful performances they sulk and pout, fret and cry, run and hide, and disobey their parents? If you will look about among your acquaintances you can no doubt pick out not a few the thought of kissing anyone of whom would cause your appetite to vanish and the natural quietude of your stomach to be disturbed, and yet would you compel a child to submit to an act distasteful to yourself, as if its olfactories were less acute and its delicate stomach less easily offended?

---

[1] How Shall We Feed the Baby? Archives of Pediatrics, April, 1885.

There are many diseases met with in children which I believe are communicated by kissing. Frequently we see diseases that are not classed as contagious, and yet all the children in a family have them. Probably in such a case the disease was transplanted in kissing, and this opinion seems reasonable when we observe that such diseases usually make their appearance on the face or lips. Among this class may be mentioned herpes, eczema, and ulcerative stomatitis. Most parasitic diseases are conveyed by close contact only, and their frequency in childhood may, not improbably, be attributed to the frequency of this vicious custom. I have no doubt that in isolated cases of eruptive diseases, when every one is puzzled to find the origin, inquiry might reveal the fact that the child was inoculated by the germ from the lips of a distant relative, friend, casual visitor or stranger who had lately kissed it.

As the child approaches puberty a marked difference in the sexes is noticeable. The girl becomes wary of the caresses of the boy, and this I believe to be the result of instinct rather than of reasoning, parental precept or education. With this period the innate modesty peculiar to woman becomes manifest. She refuses to romp and play childish games, and assumes more dignified airs. No one but the girl who is undergoing this physiological change can properly appreciate the perplexing difficulties encountered in adapting her mode of life to the requirements of her age. She must restrict the heretofore privileged bachelors by drawing the line of their salutations at hand shaking. By thus asserting her womanhood she not only offends these sage visitors, but also, perhaps, establishes a reputation among her eligible spinster relatives for haughtiness, prudery and general disagreeableness.

At this critical age it is entirely different with the boy. He who was admonished or perhaps chastised by his parents for being shy, diffident or unwilling to be kissed, suddenly astonishes the family by an entire change of disposition. He too begins to feel the importance of his age, and, unlike the girl, takes every advantage the opposite sex will give. Boys at this age are very susceptible to the flattery of escorting young ladies about, and are quick to perceive the advantage of being accommodating and polite. They enjoy the company of ladies who consider them little boys, and for their good behavior and politeness reward them with a kiss. When such freedom is given a boy at such a critical and susceptible age may we not conclude that the consequences will be harmful? If women would adhere to the strict *regime* they adopt upon entering their "teens," and not depart from it to reward the civilities of youth, it would do more than any other restriction to correct these abuses of kissing.

One of the most fortunate reformations of childhood would be the abolition of kissing games. I think the custom is gradually dying out. Only a few years ago a party of children could not amuse themselves without spending most of their time at these games. If a child were independent enough to refuse to join in such pastimes it was either "shamed" into it or adjudged disagreeable. Ringworm is a very common disease among school children, and its most frequent seat is the face. These games used to be one of the most common amusements of children during their play-hours at school, and I am convinced that the rapid spread of this disease could have been directly traced to the promiscuous kissing in these games. I also believe that if the spread of the contagium of many other local diseases of the face and scalp could be traced it would be found to originate in the same cause.

Many of the vices of later childhood may, I believe, be caused by early and undue excitement of the undeveloped sexual organs, caused by this vicious custom of promiscuous kissing. It may be contended that no physical injury can be done at this age on account of the imperfect procreative functions, but we know that repeated excitation of any organ hastens its development, and that there is such an intimate relation between the lips and the sexual organs that excitation of the former by kissing must necessarily cause excitation of the latter, and consequent premature development. Some may claim that the child's sexual organs are not excited by kissing, but the facts do not sustain this opinion, and, on the contrary, demonstrate its error. I firmly believe that frequent kissing induces precocious puberty, which we all know is injurious to the moral, mental and physical well-being of the child, and I have no doubt that hyper excitation of the passions of the precociously developed child is the frequent cause of diseases incident to unnatural irritation and congestion. I have in mind a case of serious irregularity in menstruation, in a girl of 14 years, which I was clearly able to trace to its origin in this pernicious custom.

In attacking such a universal custom with the hope of offering a remedy for it I am conscious that it is much easier to suggest a specific for the cure of a great social evil than to apply it. The suppression of the kissing salutation must be a matter of education and will not be an immediately accepted reformation. We cannot hope that all the parents of to day will promptly see the possible dangers in promiscuous kissing. It would be ridiculous to expect that any family would exclude kissing from its methods of salutation. Indeed, under ordinary circumstances, it would seem unreasonable in a mother to refuse to allow members of her own family to kiss her child, and yet it would, undoubtedly, be fully justified by all reasonable people if she should insist upon it being exclusively a family privilege, and even a member of the child's own immediate family who has either a benign or malignant disease of a contagious nature should unhesitatingly be excluded from this privilege if the mother desire to secure the safety and health of her offspring.

Under no circumstances should persons whose histories are either doubtful or unknown be allowed to kiss children. Nurses should be carefully instructed in the dangers of the custom, and should be strictly cautioned to exercise vigilance in order to protect the child from the kisses of strangers. Neither should they be permitted to indulge in the habit.

When the child is old enough to appreciate the dangers it should be taught to respectfully decline the proffered salutation. If it were taught to refuse every one then there would be little fear of offending sensitive people. If a child seem unwilling to be kissed the parent should never compel it to submit, and for disobedience in this respect it should never be punished. It has a reason for its refusal, although it may be incapable of imparting it. Children should not be encouraged to play kissing games.

As the child approaches puberty there should be a freer communication between it and the parent. The latter should point out the approaching physiological changes and their attendant dangers—prominent among which I place kissing.

To correct the abuses of kissing will not be an easy or enviable task for the mother, but if she will begin to correct them soon enough it will not be long before she will be able to eliminate this almost vice from the category of the probable causes of disease.

In offering the above suggestions to the thoughtful consideration of this Society I have no desire to achieve martyrdom in the eradication of what may be called one of the great social evils. I have only aimed to point out a few of its many dangers which are well known to medical men, and I trust that it may be the means of inducing the mothers of the coming generation to take the initial step towards curtailing if not wholly suppressing this insincere, commonplace and dangerous mode of salutation.

1525 I St., Washington, D. C.

MEDICAL PROGRESS.

INFLUENCE OF KAIRIN, THALLIN, HYDROCHINON, RESORCIN AND ANTIPYRIN UPON THE HEART AND BLOOD VESSELS.—In a series of experiments on this subject, DR. H. G. BEYER draws the following conclusions:

Kairin.—The conclusions which we may draw from experiments on the frog's tongue with kairin are (1) that it produces dilatation of the capillaries and veins, which dilatation much exceeds that of the arterioles, which latter is sometimes preceded, sometimes followed, by an abnormal contraction; (2) that it causes a slight acceleration in the current in the arterioles and a slowing of the flow in the small veins.

All the experiments made with kairin on the heart (nine in number), show the great weakening effect it exerts upon the contracting power of the cardiac muscle. In some cases in which this organ happened to be in good working order, and low venous as well as arterial pressure was used, a very slight but transient increase in the rate, and even in the force of its contraction was noticed when the dose was not too large; but this was always quickly followed by signs of general weakening. The entire organ, then, becomes much enlarged, occupying from twice to thrice its normal volume, its contractions become peristaltic, incomplete, and sluggish; the auricles keep well filled with blood, never emptying themselves completely. As a rule, the auricles are much sooner affected and recover much later than the ventricle. Under these circumstances the rate of the heart is much decreased, the amount of work done is sometimes increased, owing to the relaxed condition of the ventricle, but more often decreased, and, finally, diastolic arrest ensues. The heart presents the color of kairinized blood, which, however, again disappears, but, after repeated kairinization, it becomes permanent—in other words, the color of the blood has become the color of the muscular substance of the heart. From this condition the heart was never found to recover; the organ seems as if gelatinized, moves *in toto*, shrinks, and contracts little by little, responds to neither mechanical nor electrical stimulation, and is to all appearances dead. This condition of the heart may almost at once be produced by injecting a two per cent. solution of kairin into its substance, by which arrest in systole is produced.

The temporary diastolic cardiac arrest which kairin produces is most probably due to its stimulating effect on the terminal filaments of the pneumogastric, and the vascular dilatation to a similar influence on the ganglia of the vaso dilators. Kairin must also be considered a muscle poison.

From the results of experiments, it is quite clear that kairin reduces temperature, both by diminishing heat production and by increasing heat radiation. The distinctive influence it exerts on the red blood-corpuscles, however, and the weakening effect upon the heart, render its employment objectionable and dangerous.

Thallin.—Summing up the results of experiments with thallin upon the heart and blood vessels of the frog and terrapin, we notice, first, the striking similarity which exists between it and kairin, the only difference, in fact, being that thallin has a much less injurious influence upon the ventricle, the auricle and blood vessels being equally affected by both drugs.

The temporary diastolic cardiac arrest produced by both these drugs we are inclined to attribute for the most part to their stimulating influence on the terminal filaments of the pneumogastric. The dilatation of the blood-vessels, most probably, is produced by their stimulating effect upon the ganglia of the vasodilators. The subsequent contraction of both heart and arterioles is due to their direct action upon the muscular substance.

Thallin, like kairin, reduces temperature by diminishing heat production, and by increasing heat radiation; as an antipyretic it is less dangerous, but no less objectionable, than kairin, for while its effect upon the ventricle of the heart is less depressing than that of kairin, its influence upon the blood-corpuscles is sufficient to condemn it.

Hydrochinon.—From all the experiments made with hydrochinon on the heart and blood-vessels of the frog and terrapin, we must arrive at the conclusion that it reduces temperature mainly by increasing heat radiation owing to its influence upon the veins, which it largely dilates, and the capillaries and arterioles, which it also dilates, though to a less extent. Through its influence upon the red blood corpuscles it probably also diminishes heat production, by an impairment of their respiratory capacity.

The singular but noteworthy fact, observed under the microscope on the frog's tongue and elsewhere, that kairin, thallin, and also hydrochinon change the color preferably of venous blood, seems to point to a peculiar affinity of these substances for such blood, and it is not at all unlikely that the presence of carbonic dioxide in venous blood is the cause of its chemical decomposition underlying the appearance of this phenomenon. The peculiar coloring principle thus set free diffuses itself through the walls of the veins into the neighboring tissues.

When we now compare the action of hydrochinon upon the heart and the blood vessels of the frog and terrapin, with that of kairin and thallin, the result shows that hydrochinon affects the ventricle of the heart still more favorably than thallin; the auricles, however, are as promptly paralyzed by hydrochinon as they are by thallin, and even kairin. All three largely dilate the veins, for which they show a decided preference, and they also dilate the capillaries and arterioles; the dilatation of the latter, however, is either preceded or followed by an abnormal contraction, especially noticeable when the drug was injected hypodermatically. On hypodermatic injection of all three of the drugs, slight muscular spasm may be seen on the frog's tongue.

The action of hydrochinon, then, being similar to that of kairin and thallin so far as the heart and blood-vessels are concerned, the explanation of its action must, in like manner, be similar. The peculiar affinity of kairin, thallin, and hydrochinon for veins and venous blood cannot be explained by these experiments.

Resorcin.—A consideration of the results of the experiments leads to the conclusion that resorcin reduces the temperature by increasing heat radiation by the dilatation it produces in the capillaries and veins, especially the latter. The same quite remarkable preference for the venous side of the heart and vascular system is shown by resorcin in nearly the same degree as by thallin and hydrochinon. Resorcin paralysis the auricles in doses which seem to improve rather than impair the contracting power of the ventricle, and it largely dilates the veins, while the arterioles are affected but very slightly.

As is the case with kairin, thallin, and hydrochinon, resorcin reduces the rate of beat of the heart probably by a stimulating influence on the terminal filaments of the pneumogastric, and dilates the vessels through a similar influence on the ganglia of the vasodilators. The tonic effect which it has upon the ventricle is most probably due to its direct action upon the muscular substance of the heart. We have, so far, no explanation of the difference in the action of these drugs upon the two sides of the heart and vascular system. Nevertheless, the fact remains that all of the drugs so far considered possess this property nearly to the same extent. The only difference regarding their influence upon the heart lies in the ventricle. Kairin and thallin, in small doses, exercise but a *temporary* tonic influence over its contraction; hydrochinon and resorcin a more permanent one. They all quickly paralyse the auricles and lower the tone of the walls of the veins. The natural consequence is that a much greater quantity of blood will be contained in the veins than in the arteries, and its passage from the veins back into the ventricle is greatly impeded, owing to the paralyzed condition of the auricles. Collapse, therefore, ensues, not so much from failure of the action of the ventricle, as from the danger of *bleeding the animal to death into its own veins*, to use the words of Ludwig.

Antipyrin.—Antipyrin, in very small doses, injected into the lymph sac of the frog very slightly contracts the arteries, but dilates the capillaries and veins; in large doses, applied directly to the surface of the tongue, it gives rise to extensive dilatation in the veins and also the capillaries; a 1 per cent solution of it applied to the tongue of the frog will, after a short time, cause coagulation in all the superficial blood vessels. The manner in which antipyrin reduces temperature is purely by increasing heat radiation, owing to its extensively dilating the veins and capillaries; but what stamps it is an excellent antipyretic is that, besides dilating the veins, it also has a tonic influence on the heart and slightly increases arterial pressure, or at any rate does not cause a diminution of the same. It has, moreover, no injurious influence on the blood or the muscular tissues, and strengthens the auricles.

The objection to the employment of kairin and thallin as antipyretics is from the fact that they cause heart paralysis, especially affecting the auricles, in doses only slightly larger than are sufficient to produce a lowering of the temperature. But this objection becomes an absolute danger when we take into account the destructive influence upon the blood corpuscles and tissues generally.

Hydrochinon and resorcin, although not exerting the same weakening and directly paralyzing influence upon the ventricle of the heart which is peculiar to kairin and thallin, both paralyze the venous side of the heart, viz., the auricles, and greatly lower the tone of the walls of the veins. The extra amount of blood, therefore, which is driven into the veins through the increased action of the ventricle, is only with great difficulty returned to the ventricle, and here the danger is not so much from failure in the power of the ventricle as in the case of kairin and thallin, as from the danger of *bleeding the animal to death into its own veins*. The intense visceral and especially pulmonary congestion found on post-mortem, by Dujardin Beaumetz, and others, in animals killed by resorcin, seems to confirm this view of the matter.

Antipyrin, though largely dilating the veins, increases the power of contraction of both auricles and ventricle, and has no injurious influence upon the blood nor the muscular tissues, and therefore possesses, indeed, all the good qualities of a perfect antipyretic.—*American Journal of the Medical Sciences*, April, 1886.

Successful Splenectomy.—At the meeting of the Royal Medical and Chirurgical Society, on April 13, a paper by Mr. Knowsley Thornton was read, which was of remarkable interest, as embodying an account of the first successful case out of twelve operations for the complete removal of the spleen, which have been performed in England. The operation was performed almost exactly two years ago, on April 22nd, 1884, for the relief of a painful and rapidly growing splenic tumor, in a girl of 19. It proved to be one of the multilocular cysts, which are very rarely found in the spleen, and which had reached a dangerous stage; for the walls of the cyst had in one part become so thin, as to be quite transparent, and rupture might have followed any trifling accident. The specimen was shown to the Pathological Society, soon after removal. No traces of any hydatid origin could be discovered. The patient was anæmic, but the increase in the proportion of colorless corpuscles was not great, and there was no enlargement of the thyroid or other glands. The operation was strictly aseptic. There was a speedy recovery, interrupted by a relapse in the third week, with some fever and phlebitis; but, in seven or eight weeks, good health was re-established, and what is very important to notice, has been continued up to the present time; so that the physiologist has a rare opportunity of studying the working of the human economy, when deprived of one of its large visceral organs, whose functions, in spite of much study, remain somewhat enigmatical. Mr Thornton was able to give the very satisfactory report of his patient, that, after recovery from the immediate effects of the operation, she had spent nearly two years in comfort, and, apparently, normal health; into any more minute physiological points he had had no opportunity of entering. In the very interesting tables of previous operations, which he presented along with his paper, there were thirteen for simple hypertrophy, of which nine recovered. The first splenectomy in England, that by Sir Spencer Wells, in 1865, was for simple hypertrophy; but the patient died in a week, with a large thrombus in the heart. M. Péan was quite successful in 1867, in the removal of a spleen containing a very large cyst, which held more than five pints of viscid fluid. That was the first success since a rather doubtful case by Ferrerius, in 1711, and by Zaccharelli, in 1540. In the many cases, now reaching a total of about twenty, in which the operation has been recorded, as having been resorted to in cases of undoubted leukæmia or leucocythæmia, it has invariably been fatal; and Mr Thornton was no less emphatic than other authorities, in its condemnation, under such circumstances; and, though these, unfortunately, are by far the largest number of cases in which great splenic enlargement is associated with fatal disease, yet a small residuum remains of cases of great pain, such as sometimes accompanies wandering spleens, and sometimes of great danger, as in cystic disease, in which the advances of abdominal surgery offer us some hopes of permanent relief.—*British Medical Journal*, April 17, 1886.

INTRAVENOUS SALINE INJECTION IN POST PARTUM HÆMORRHAGE.—The value of intravenous saline injection in metrorrhagia is warmly advocated by DR. F. WEBER in the *St. Petersburger medicinische Wochenschrift*. Its superiority over transfusion of blood, human or animal, consists partly in the simplicity of the apparatus required. All that is needed is an Esmarch's jar, with a glass reservoir, a canula, and some India rubber tubing. The operation is as follows. Five litres of a 6 per cent. solution of common salt is prepared with distilled water of the temperature of the body. If the veins be so collapsed as to be invisible through the skin after ligation of the upper arm, a vein is exposed, and two ligatures passed under the free portion; the distal end is tied, a longitudinal incision is made in the vein, and a glass canula introduced, filled with saline solution, which is then fastened by means of the second ligature. This, and the pressure of the finger on the vessel, prevent the air from entering the veins. The canula is then connected, by tubing, with the jar containing the whole quantity of the solution. Directly the finger is removed, the injection begins. No ill effects are seen. Dr Weber relates an instance in which this method was most valuable. He was called by a midwife to a married woman, aged 21, who was seized with *post partum* hæmorrhage fifteen minutes after the birth of a putrid child. Dr Weber arrived at 10.30 P.M., an hour after the hæmorrhage had commenced. He found the uterus atonic, reaching to the umbilicus. Massage, hot injections, and hypodermic injections of camphor and ether, were used, with some effect. The hæmorrhage returning, he was called at 3 A.M., and after hot douches and ice-tampons, it again decreased; but cerebral anæmia appearing to an alarming extent, and the pulse being imperceptible, hot compresses were placed on the head, the lower extremities bandaged, and hypodermic injections administered every quarter of an hour. These proving unavailing, it was decided to try an intravenous saline injection. This was successfully administered; and when 500 grammes had been given, hæmorrhage ceased, and the patient who had been conscious the whole time, experienced great relief. The pulse, too, became distinct. On 1,000 grammes being injected, the patient complained of palpitation, and the jar was lowered in order to lessen the pressure on the circulation. When 1,500 grammes had been injected, the pulse was perfectly good, and the cerebral and hæmorrhage symptoms disappeared. The patient felt completely invigorated, and took nourishment without vomiting. She continued to do well, and made an excellent recovery.—*British Medical Journal*, May 1, 1886.

THE HAIR ROOTS AS INDICATORS OF BODILY OR MENTAL DISEASE.—DR. J. POHL-PINCUS, of Berlin, has recently in a *brochure* entitled "Polarised Light as a means of recognising Irritable Conditions of the Nerves of the Scalp," announced that by an examination of the hair roots by polarised light peculiar changes may be observed whenever the patient suffers from physical irritation or mental excitement. This statement is the result of investigations which have now been going on for twenty-five years, and the later observations in the course of the research have uniformly confirmed those made earlier. The hair bulbs are divided into three groups, as follows. Group A. If, in healthy conditions of the body and mind, the hairs that fall out daily are examined microscopically by polarized light, the enlarged bulbous end of the root will show a white contour, and a yellowish or brownish red centre Group B In all irritable conditions of any organ, also in emotional disturbances of moderate grade, without any apparent bodily disease, the bulbous end of the hair root increases in length and breadth (in proportion to the irritation), the central part appears under polarized light of a violet, blue, or bluish green color, separated from the white contour by bands of yellow and red Group C In higher grades of bodily disease or mental disturbance, the bulb becomes still larger, and the bluish centre changes to green, yellow, or orange A few hairs of the B and C types are found in normal conditions, especially in those more advanced in life Dr Pincus gives thirty one cases showing the effects of painful disease, but more especially of depressing emotions, upon the appearance of the hair root The conclusion to be derived from these researches is that bodily disease or mental excitement causes circulatory disturbances, and in consequence a change in the normal nutrition and pigmentation of the hair This is only in accordance with previous observation, and the chief merit of Dr Pincus's plan lies in his obtaining a means by which very slight and temporary changes in tissue growth can be detected and approximately measured —*Lancet,* May 1, 1886

Urethan —MM Mairet and Combemale have addressed the following communication to the Academy of Sciences "We have administered urethan 300 times, to thirty-seven insane patients, with whose form of insanity we were acquainted The doses varied from ½ gramme to 5 grammes, given in twenty-four hours When we administered urethan to insane patients, with whose symptoms and condition we were not thoroughly acquainted, it was given to them several times The mental affections of the patients may be classed as follows mania, 13, lypemania, 2, imaginary persecution, with sensorial faculties perverted, 3, insanity, consecutive to mania or lypemania, 9, insanity, consecutive to atheromasia, 3, paralytic madness, 7 In paralytic insanity, and insanity from atheromasia, strong doses of urethan did not have any hypnotic effect In the other forms enumerated, the effect varied according to the excited state of the patient, when this is very intense, the drug does not have any hypnotic effect, but appears to increase the excitement In less excited conditions, urethan produces sleep, which is calm, regular, and free from nightmares, the patient wakes up easily from a slight noise, or any other disturbing influence, but quickly falls asleep again Sleep from urethan generally lasts from five to seven hours, and is not followed by any disagreeable sensation Nutrition does not appear to be affected by urethan, even though it be given during fifteen days From 2 to 5 grammes produce sleep, but not smaller doses, if 5 grammes be given as a first dose, and fail, it should not be continued Its action is generally quick, some times two or three hours elapse before sleep results Its action is not lasting, after two or three days, or six or seven days, according to the patient, it fails to produce sleep, its use must then be discontinued during some days The earlier and the sounder the sleep resulting from its influence, the sooner is that influence exhausted " MM Mairet and Combemale's physiological researches on the action of urethan, published in the *Comptes Rendus de la Societe de Biologie,* March 20, 1886, indicate that this substance acts directly on the nervous system —*British Medical Journal,* May 1, 1886

Permanganate of Potash in Amenorrhœa — Dr Lee O Rogers, of San Francisco, reports the following case in corroboration of the article of Dr Billington in the *Medical Record* of March 6 "Miss F, aged 19, was sent to me for advice, and gave the following history She leads an active life when at home, spending much time in the open air In July, 1884, she came to a town adjacent to this city on a visit to friends She began shortly after to grow 'stout,' her abdomen particularly becoming prominent Her menses disappeared entirely after the period in July, previous to which she had always been perfectly regular In March, 1885, she was sent to me by her hostess, who thought her pregnant, for the purpose of being kept in the city and confined The girl seemed to be remarkably healthy and was very 'fat,' and she proved, upon physical examination, to be a virgin I immediately put her upon potassium permanganate, a 2 grain compressed tablet, four times a day, each tablet to be followed immediately by a large gobletful of water Much nausea and some vomiting occurred during the administration of the medicine, but I attributed this to the fact that I gave the tablets on an empty stomach, as I accepted Bartholow's theory of the action of the drug On the fourth day of the administration of the permanganate the menses appeared and lasted four days, after which the patient was sent to her home She was instructed to inform me if her menses failed to appear on time after her return home, but I have not heard from her " —*Medical Record,* April 17, 1886

Healing by First Intention after Operation for Fistula —Dr Ruidnovski, having found that after operations for anal fistula in rural districts where there was no hospital accommodation, and where the hygienic conditions were bad, it is often difficult to get the wounds to heal by second intention, determined to make an attempt to obtain union by first intention by means of sutures A boy of 14 with an anal fistula was operated upon in this manner, the sinus was found to be not single, but complicated with two lateral sinuses After the incision had been made into the gut, the soft tissue between the sinuses and the granulations were all scraped away with a Bruns sharp spoon, the surfaces of the wound being brought together by a deep and a superficial row of sutures Opium was given, and in a week's time the dressings were removed and the wound was found to have healed perfectly by first intention —*Lancet,* April 17, 1886

ANTIPYRIN IN INFANTILE THERAPEUTICS

We have recently received from DR MONCORVO, the well known Brazilian clinician, a copy of his latest brochure, "De L'Antipyrine dans la Thérapeutique Infantile," from the press of O Berthier, of Paris Dr Moncorvo has already contributed several valuable papers on the action of the new antiperiodics and antipyretics, the most notable being one "De la Coqueluche et de son Traitement par la Résorcine" He is known as a most careful observer and a correct interpreter of facts, and whatever comes from his pen may be received as entitled to the highest consideration

The work before us is a well printed pamphlet of 156 octavo pages, divided into four chapters, the first chapter being chiefly historical Dr Moncorvo has used antipyrin in bronchitis, broncho-pneumonia, tuberculosis, acute impaludism, in rheumatic fever, and in grave cases of fever of suppuration The cases in which it has been used number more than one hundred In the first case recorded, one of acute impaludism with acute bronchitis, a child only five months old, who easily bore a dose of 5 grms and a half of antipyrin in five days The rectal temperature, which for the first four days had been between 39 5 C and 40 6 in spite of the use of sulphate of quinine, commenced to fall almost immediately after the administration of antipyrin, and continued to fall for four days On the first day it fell 2 4 C in an hour and a half, after a dose of 50 centig With the fall of the temperature the bronchial and pulmonary phenomena were rapidly ameliorated In another case of bronchitis with impaludism the rectal temperature fell 4 5 C within one hour and a half In a third case, that of a child two months old, the temperature fell 2 C in 30 minutes, and the child recovered, though it was suffering with whooping cough, broncho-pneumonia, and pernicious fever These are three cases from nine records They all show that young children easily bear the administration of antipyrin, and that large doses may be administered with comparative impunity, and Moncorvo declares that the action of antipyrin is much superior to that of quinine administered subcutaneously In some of the cases, in fact, quinine failed completely

Dr Moncorvo is enthusiastic over the action of antipyrin in cases of pulmonary tuberculosis The defervescence, sometimes very rapid, which follows the administration of this remedy, always causes a considerable calm The appetite returns, the insomnia and agitation, so frequent at night in the little patients, is followed by tranquil sleep, which in a great measure contributes to the improvement in the general state If it be true that the action of antipyrin is transitory, it at least possesses the very great advantage that it may be administered for a long time without fear that it will accumulate in the organism, and that it will have no serious effects on the digestive apparatus or the nervous system One very striking circumstance in connection with the use of antipyrin in these little patients, is the marked modification of the congestive pulmonary phenomena which so often accompany the evolution of the malady, and the frequency of this modification when the medicine is properly administered leaves scarcely a doubt as to the favorable action of antipyrin on the pulmonary circulation This view is supported by that of Cahn, that antipyrin acts in pneumonia not only as an antipyretic, but that it has a direct action on the pneumonic process Moncorvo states that even when so much as 2 grams of antipyrin was administered in twenty-four hours he has not seen the excessive sweats which have been mentioned, and that he has altogether dispensed with the use of agaricine, as devised by Norden, or of atropia, as proposed by von Hoffer He believes that his experience authorizes him to say that antipyrin administered to children in the course of the febrile manifestation of pulmonary on visceral tuberculosis acts admirably by causing a defervescence, which is maintained for several hours, and sometimes even for a whole day, without the production of any untoward result In some cases the defervescence is almost mathematical after the ingestion of a dose varying from 1 to 2 grams

Guttmann and others believe that antipyrin and kairin have no effect on intermittent fever, and the question as to their value in impaludism may be regarded as still *sub judice* The opinion of Moncorvo may be regarded as of exceptional value in this question, for there can be no question as to his facilities for observing malarial fevers in all forms and stages He says I have been forced by the evidence to regard antipyrin as of powerful utility when it is associated with various salts of quinine I am fully in accord with Guttmann, Huchard and others when they say that antipyrin has no specific action on the germ producing paludal intoxication I consider the hypothesis raised by Laveran as entirely admissible that quinine cures malarial fever by acting directly on the microgerms existing in the blood Antipyrin may be regarded as having a parallel germicidal property, it cannot replace quinine, but it has the undeniable property of subtracting heat or of abating the high temperatures of grave paludal fevers, with a rapidity evidently superior to that of quinine, while by the free diaphoresis which it causes it opens a large portal for the elimination of the toxic agent Furthermore, by causing free defervescence, without compromising the forces of the organism already enfeebled, antipyrin creates a condition very favorable for the absorption of quinine The gravity of the case is not to be judged in all cases by the height of the temperature, since the value of this sign varies according to the nature of the fever, it may be admitted that the exaggerated combustion of which hyperthermia is the expression causes grave regressive disorders of the viscera in exposing the organism to a very great danger In a general way, then, and particularly in cases of children, it is always well to take into consideration the thermic element in the treatment of febrile affections The ideal of the therapeutics of malarial fever will be realized by an agent which will possess the property of rapidly lowering the temperature, while acting simultaneously on the germ producing the disease But while awaiting such an agent, he thinks, we cannot do better than to employ antipyrin and quinine successively

As regards the dose and methods of administration, Dr Moncorvo says that while our German *confreres* have given too large doses to adults, their experience has made many fearful of moderate doses for children When he first began to use it he gave doses of 20 or 25 centig, but gradually recognized that children could tolerate and needed larger doses, and that children are much more tolerant of the drug than adults Half an hour after the first dose of 25 or 50 centig or 1 gram had been given the temperature is taken in the hand, and the next dose is graduated according to the fall noted In another half hour the temperature is again taken, and another dose given if the temperature be still high Generally in one or two hours the temperature falls one, two or three degrees, though he has not given more than 3 grams in this time He has had no cases of collapse from antipyrin, and the only inconvenience that he has noticed is the occasional vomiting, which he says is no more frequent in children after taking antipyrin than after the ingestion of other drugs It may be administered to children either by the mouth, rectum, or subcutaneously In the first instance it is invariably given in aqueous solution, aromatized with mint or anise If after taking it some time the stomach of the child rejects it, the syrup of currant or gooseberry will usually mask the taste completely Its great solubility precludes the necessity for a large volume of the vehicle When it is thought proper to give it by rectal injection it is well to precede this by an injection of a 2 or 5 per cent solution of muriate of cocaine, and then give the antipyrin within four or five minutes The experience of Huchard that when given hypodermatically the action on the temperature is less marked is not confirmed by Moncorvo's experience, nor is there, according to him, any objection whatever to giving the drug in this manner, and he has so given it to the youngest children The conclusions which he draws in regard to the drug are as follows

1 On account of its remarkable activity, and its almost mathematical regularity of action, as well as on account of its absolute harmlessness in moderate doses, antipyrin is the most powerful and the least dangerous of the antipyretic agents employed to day in infantile therapeutics 2 When given in the course of specific or non specific inflammatory affections of the respiratory apparatus the defervescence is, almost without exception, very rapid, more or less lasting, and causes at the same time an amelioration of the general state In tuberculous subjects the continuous administration of this drug often causes a very favorable modification of general nutrition, on account of a reestablishment of appetite, the disappearance of insomnia, and at the same time a notable amelioration of the cough 3 In the treatment of acute impaludism, antipyrin is very efficacious, contrary to what has been affirmed by almost all observers Without any demonstrated specific action on the germs of malarial intoxication, it answers in benign and transient cases by its antithermic action and frank elimination through the skin In severe cases it is of great service by facilitating a more prompt and more efficacious absorption of salts of quinine It is thus a powerful adjuvant to quinine by preventing intermittences, so that the maximum

temperatures are lower 4 In the treatment of some cases of acute rheumatism, and in whatever concerns the febrile element in these cases, its action appears to be very analagous to that of salicylate of soda 5 In several cases of surgical affections accompanied by a commencing septicæmia, antipyrin caused remarkable modifications of general nutrition by the continued subtraction of heat, which was very high in young children 6 Defervescence caused by the drug is produced with mathematical regularity in children of every age, and varies from six to twenty-four hours The succeeding ascent of temperature takes place in an insensible manner, contrary to what is seen when carbolic acid, kairin, and thallin are used 7 It has already been said that no serious accidents have been caused by the drug in Moncorvo's hands 8 Antipyrin has a manifest action on the circulatory apparatus, slowing the heart and the pulse Its influence on vascular tension has not been determined The diminution in the frequency of the pulse and the lowering of the temperature are rarely ever proportional 9 It has scarcely any appreciable modifying action on respiration 10 The urinary secretion is somewhat diminished, but this is usually proportional to the abundance of the sweat Some examinations have shown a decrease in the amount of urea It does not cause albuminuria, and has been known to check it

A DOCTOR'S EXPERIENCES IN THREE CONTINENTS

Such is the title of a most interesting and charmingly egotistic book of some six hundred pages by Dr Edward Warren-Bey It is in a series of letters to Dr John Morris, of Baltimore, and being in the form of letters to an intimate friend the frequent use of the first personal pronoun, so far from being at all disagreeable, adds to the interest of the volume The letters are not in the form of a diary, but facts, dates and comments are given in a manner which is at the same time connected and disconnected The personal memoirs of distinguished men are always of interest, particularly when well written, and it is apparent from these letters that Dr Warren's fluency of speech is not greater than his readiness with his pen

A man who took an active part in the surgery of the late war, who has been an active practitioner in two sections of this country, chief surgeon of the Egyptian War Department, and for some years an active practitioner in Paris, the friend of the much lamented Otis and Gross, of Charcot, Zeb Vance, Ismail Pasha, Landolt, Abbate-Bey, General Mott, Alfred Swaine Taylor, Thomas Stevenson, and Sir James Paget, could but have an interesting history Very much of this written history is a record of trials and sorrows, some of which must come to everyone, and of difficulties overcome Perhaps one of the most remarkable facts in the life of Dr Warren is that he did not study the profession of his first choice —law— but was induced by his father to study medicine This is chiefly remarkable on account of his eminently successful career as a physician

Taken altogether, we do not know of any book the reading of which will make an evening pass more quickly or more pleasantly, and the chief regret on parting with it is that it is not longer For those who are inclined to believe that there is nothing good in America, who buy their watches in Geneva, their umbrellas in Paris, and their ill-fitting clothes in London, we particularly recommend the following, from the last letter —"Before bidding you adieu, I must say this much The longer I have resided abroad, the more intensely American have I become, and the greater has grown my love and appreciation of my native land Other lands may possess their treasures of art, their marvels of luxury, their triumphs of architecture, and all that is calculated to captivate the imagination and ravish the senses, but for the truest solution of the problem of human existence, the grandest victories of human skill over the laws of nature, the most fortuitous combination of those conditions which constitute society, and the perfection of a governmental system—that which governs the least and protects the most—America is the land preeminently blessed of Heaven Call me an enthusiast if you will, but for me her skies are the brightest, her mountains the grandest, her rivers the broadest, her fields the greenest, her women the loveliest, her men the noblest, her history the proudest, and all that relates to her the best of all the world besides Elsewhere her sons may be content to linger for a season, but to them she is the only land in which they can ever realize the idea of *home*, or feel that they are aught else than aliens and sojourners"

A RATIONAL CONCLUSION

The editor of the *Medical Record*, of May 15, in speaking of the organization of the Executive Committee of the Ninth International Medical Congress says "But the organization and management are definitely settled, and we have no desire now to hamper its future work We do not think that hereafter the International Medical Congress will meet with any aggressive opposition or criticism Its managers have chosen their course, and we shall be glad, for the sake of our country's reputation, to see them successful in it" In another paragraph, the same editor says "Still, we say to foreign delegates, You will meet a large number of able and hospitable gentlemen at the Congress, you will be made warmly welcome by all Americans, and you will hear no quarrelling while you are in the States"

Kindly sentiments and assurances of future peace, even though late in finding expression, are none the less welcome And if the Executive Committee of the Congress is to be permitted to carry forward its responsible work without further opposition, "our country's reputation" will be abundantly vindicated by the result

A NEW COLLEGE OF PHARMACY

Some two months ago a number of prominent pharmacists, who were active members of the Chicago College of Pharmacy, withdrew from this organization, and five of them have founded a new school, known as the Illinois College of Pharmacy The government of the Chicago College of Pharmacy is in the hands of a College Association, composed almost entirely of the younger alumni, who sometimes have been capable of committing very strange blunders, such as electing young and inexperienced graduates to the Board of Trustees of the college After trying in vain to give to the college a more stable and rational organization, the oldest and best known of the trustees withdrew, leaving the school entirely in the hands of the younger element

The Illinois College of Pharmacy is governed by a board of five trustees Wm Bodemann, D R Dyche, H S Maynard, T H Patterson and E H Sargent Their names are a sufficient guaranty of stability, as all are well known throughout the West

Professors Oscar Oldberg and J H Long withdrew from the faculty of the old school and have been elected to the Chairs of Pharmacy and Chemistry in the new The new school will be the Pharmaceutical Department of the Northwestern University

IN MEMORY OF PROFESSOR AUSTIN FLINT —During the session of the Executive Committee of the Ninth International Medical Congress, May 3, 1886, appropriate resolutions were unanimously adopted expressing their high appreciation of his character and noble life work, and their deep regret for the loss of the late President of the Congress

A just tribute was also paid to his memory by the President of the American Medical Association in his Annual Address, on the first day of the meeting of that body in St Louis, May 4, 1886, and another was contained in the report of the chairman of the Standing Committee on Necrology, which was called for on the last day of the session and referred for publication

PRIZES OF THE AMERICAN MEDICAL ASSOCIATION —We have received two anonymous letters asking for information regarding the prizes of the Association and the regulations governing their award We think the only action taken by the Association concerning prizes during the last two years can be found in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION Volume V, page 531, number for November 7, 1885, and relates to prizes of honor only

NOT VERY ACCURATE —The *Medical News* of Philadelphia, in endeavoring to give the "officers of the International Medical Congress," in its issue for May 15 inst, commits at least *four* errors of commission and *three* of omission—enough certainly for one half column

SOCIETY PROCEEDINGS

AMERICAN CLIMATOLOGICAL ASSOCIATION

Third Annual Session held at the Hall of the College of Physicians, Philadelphia, May 10 and 11, 1886

MONDAY, MAY 10, FIRST DAY

MORNING SESSION

The meeting was called to order by THE PRESIDENT, WILLIAM PEPPER, M D, LL D, of Philadelphia

THE PRESIDENT opened the session with an address on

THE CAUSES AND DISTRIBUTION OF CONSUMPTION IN PENNSYLVANIA,

being a preliminary report of investigation still being prosecuted

DR A L LOOMIS, of New York read a paper on

THE EFFECT OF HIGH ALTITUDES ON CARDIAC DISEASE

In 1880, while in the Adirondacks, the author was requested to see a gentleman who was thought to be dying The patient aged 40 years, was found gasping for breath, cyanosed, with no apparent radial pulse, and bathed with profuse perspiration Under the hypodermic use of digitalis, morphia and brandy he improved The following day it was learned that he had left New York apparently well When he reached an elevation of one thousand feet the breathing became difficult, and as a higher altitude was reached, the difficult was increased and was accompanied by cardiac palpitation and a sense of oppression in the epigastrium When he reached St Regis lake at an elevation of two thousand feet he appeared to be dying Physical examination showed well marked dilatation of both ventricles, with a loud systolic murmur heard over the præcordium and transmitted a little to the left At the end of three days he returned to New York As he reached lower levels the difficulty of breathing diminished and when he reached New York he could walk on a level The irregular heart action, however, continued, and the feet soon became œdematous and he died six weeks later with general anasarca and heart insufficiency No autopsy was made The patient had never presented any evidence of cardiac disease prior to his trip to the mountains

The speaker had seen in all twenty-six similar cases, the histories of five of which were given, one of which follows

Mrs S , aged 43, had mitral insufficiency for over ten years, but never exhibited any cardiac symptoms She went to Colorado When she reached an elevation of four thousand feet she was suddenly seized with extreme dyspnœa and hæmorrhage There was palpitation of the heart and constriction of the chest The following day she started on her return As she reached a lower level she improved Physical examination revealed extreme dilatation of both ventricles, complete cardiac diastolism, indistinct apex beat, crepitation over the base of both lungs with feeble or absent respiratory murmur The patient died four weeks after her return The autopsy showed both ventricles much dilated, old thickening and insufficiency of the mitral valve, some interstitial myocarditis and degeneration of the muscular fibre of the heart walls The right lung was the seat of pneumonia and old infarctions All the other viscera were in a state of extreme venous congestion

Dr Loomis then went on to say that in all the cases coming under his observation, the ventricular dilatation was unquestionably the cause of the sudden development of distressing symptoms, and that the commencement of the fatal issue seemed to be directly due to the effects on the cardiac circulation of a change from a lower to a higher altitude

Two important factors which lead to permanent cardiac insufficiency, are, first, the condition of pul monary distension consequent upon rarefaction of the atmosphere, and second the resultant condition of the circulating blood

If the explanation of the effects of high altitude upon the cardiac circulation be accepted, the risks which one with even slight cardiac insufficiency runs by passing from a lower to a higher altitude is certainly very great, and if the insufficiency is extensive, such changes become immediately dangerous It must be remembered that cardiac insufficiency may exist in those who give no evidence of it

Clinically the speaker relied upon what is termed the muscular element of the first sound of the heart, in determining the condition of the muscle walls Clinical experience had also convinced him that it was unsafe for one to make such change, whose cardiac rhythm was greatly disturbed by nervous excitement, or by rapidly ascending a long flight of stairs

Dr **Frank Donaldson**, of Baltimore, read a paper, entitled

A PRELIMINARY ACCOUNT IN REGARD TO CIRCULATORY AND RESPIRATORY CHANGES OBSERVED IN ANIMALS PLACED IN THE PNEUMATIC CABINET

The experiments had been performed on rabbits which had been chloralized It was found that

1 When the animal is breathing air from outside of the cabinet, rarefaction of air within the cabinet causes a marked fall of general arterial pressure, but has no influence on the pulse rate The fall of pressure lasts only a short time (ten or twenty seconds) and is often followed by a temporary rise above the normal

2 This fall of systemic arterial pressure depends on two factors,—greater flow of blood to the skin when the air around the animal is rarefied and greater accumulation of blood in the lungs when they are distended

3 Of these two factors, accumulation of blood in the lungs is the more effective, for if the animal breathes air from the cabinet, and not from the outside, rarefaction of the air within the cabinet (in this case, accompanied by no special expansion of the thorax) has but a trivial effect in lowering arterial pressure

4 When the animal is breathing external air, rarefaction of the air within the cabinet usually has no effect upon the respiratory rate, nor upon the extent of individual respiratory acts, unless the fall of blood pressure be considerable If it be considerable, symptoms of anæmia of the medulla oblongata show themselves In some cases, there is more forcible dyspnœic breathing and, in some dyspnœic convulsions similar to those which occur when an animal is bled to death, and due to the same cause, viz , deficient blood flowing through the respiratory centre

5 The rapid recovery of general arterial pressure while the animal is still in a rarefied atmosphere, but breathing external air, is probably due to excitation of the vaso-motor centre, which as is well known is excited whenever the blood power is defective

6 The brain enclosed in a rigid box which is practically unaffected by variations in the atmos pheric pressure, has its circulation more disturbed in the pneumatic cabinet than any other organ with the exception of the lungs

7 Compression of the air within the cabinet while the lungs are in communication with the external air, causes a considerable transient rise of blood pressure This is probably mainly due to the forcing of the blood from the cutaneous vessels, but there has not yet been sufficient time to thoroughly investigate this point

8 Compression of air within the cabinet while the lungs are in communication with the external air, slows the pulse as the arterial pressure rises This is probably due to the excitation of the cardio-inhibitory centre by increased intra-cranial blood pressure Further experiments are, however necessary before this can be positively stated

9 In certain cases, when the air within the cabinet is rarefied and the animal is breathing external air, the respiratory movements cease altogether for several seconds As to the cause of this physiological apnœa, we are not yet ready to form an opinion It may be due to extra accumulation of air in the alveoli of the lung, or to distension of the lungs, exciting those fibres of the pneumogastric which tend to check inspiration

The President had seen not only in the class of cases described by Dr Loomis, but also in cases of cardiac disease originating in high altitudes, the grave consequences which followed A small amount of organic lesion under such circumstances produces very serious symptoms, even preventing the patient from assuming the erect posture

Dr E D Hudson, of New York, thought that heart disease was not prevalent in high altitudes, and that the tonicity of the heart was really increased so that such persons were better able to withstand fatigue than those of a lower level The recognition of the importance of the point to which Dr Loomis has called attention would no doubt result in the saving of many lives Still, when necessary, we should not be deterred from sending patients to high altitudes, taking care that sufficient time is spent in the transition so that the circulation may gradually adapt itself to the change in altitude

Dr Loomis said that there was no danger to a good heart whose nervous condition was normal If such individuals suffer, it is only temporarily After fifty years of age, the condition of the heart walls is uncertain This high altitude is only one of the causes of over-distention of the cardiac cavities He did not believe that it was safe for any man with arterial degeneration or dilatation of the vertricles to take the chances of going into a high altitude or taxing his his heart beyond a certain limit

EVENING SESSION

Dr Herbert F Williams, of New York, read

A CLINICAL REPORT OF CASES TREATED BY PNEUMATIC DIFFERENTIATION

with the assistance of Mr Ketchum, of New York, the inventor of the apparatus, a demonstration of the working of the pneumatic cabinet was given The speaker then reported forty-five cases in addition to those previously reported, in which he had used the cabinet as a method of treatment Sixteen cases were reported in detail

Dr Vincent Y Bowditch, of Boston, reported a

TEN MONTHS' EXPERIENCE WITH PNEUMATIC DIFFERENTIATION

The speaker endeavored to give the clinical results of the treatment in thirty-seven cases since June 30, 1885 Pulmonary phthisis, in its tubercular and non-tubercular forms, bronchitis in its acute and chronic forms, with and without emphysema or asthma, and retraction of the lung from long standing pleuritic effusions, are the diseases which he had treated in the pneumatic cabinet His experience was such that although he had been unable to accomplish thus far such brilliant results as some others had claimed, yet he felt convinced of the very marked beneficial effect of the cabinet in many cases where other means had failed to give relief, and of its curative power in one case of incipient tubercular trouble, and he looked forward with hope to what may be done in the future with this new method of treatment The speaker said his chief desire was that the profession should investigate the matter thoroughly and with fairness, and publish their results, for by this means only can a just estimate of the merits of the treatment be established He felt that it should be entrusted only to a physician's care or to that of a reliable assistant, and that if placed in hospitals the most accurate methods of recording cases should be insisted upon before allowing the cabinets to be used Carelessness of investigation in the present stage of its existence might do infinite harm to a method which may prove, when properly used, of infinite service

The following table was given showing the percentage of cases in which benefit had been accomplished

19+ per cent of all the cases treated received no benefit

23+ per cent of all the cases treated received very slight, moderate or temporary benefit

46+ per cent of all the cases treated received marked benefit (for varying periods)

7+ per cent of all the cases treated received remarkable benefit

3+ per cent (one case of incipient tuberculosis) was cured

Dr I H Platt, of Brooklyn, read a paper on

THE PHYSICS AND PHYSIOLOGICAL ACTION OF PNEUMATIC DIFFERENTIATION

Pneumatic differentiation is the process by which the air surrounding the body and that entering the lungs is rendered of different densities There are three forms, which for convenience may be designated positive, negative and alternative He proposed to consider chiefly positive differentiation, which is the form in which the air surrounding the body is of less pressure than that entering the lungs The apparatus introduced to the profession by Dr Williams, and known as the pneumatic cabinet, is the most convenient for applying this treatment As the difference in pressure used is very slight, seldom exceeding that indicated by a fall of one inch of the mercurial column, the absolute change in air pressure is an insignificant factor, the essential element being the differentiation

The effect of reduced air pressure upon the periphery of the body is to increase the expansion of the thorax in inspiration and to diminish its contraction in expiration, consequently to increase the amount of residual air By the increased pressure in the lungs it will tend to exsanguinate them and to raise the arterial blood pressure in the general circulation

Two of the claims put forward by Dr Williams and Mr Ketchum he believed to be unfounded The first is that the effect of removing a slight degree of pressure from the periphery of the body is radically different from that of increasing the pressure of the air entering the lungs, the former acting as a *vis a fronte*, the latter as a *vis a tergo* One of the most elementary principles of physics teaches that suction is not a force operating from in front, but is merely removing the pressure from one side of a body and allowing the undiminished pressure to act upon the other side It makes no difference whether pressure is taken from the outside of the thorax or added to the inside, in either case it is the unbalanced pressure which causes the increased expansion The other proposition which he combats is that the spray or vapor used in conjunction with the differential process can be carried further into the air passages or more thoroughly condensed upon them than a spray or vapor could be under normal conditions They cannot be carried so far, for the reason the residual air is increased, and consequently the inspired air which carries the vapor or spray cannot penetrate so far It is claimed that the vapor of medicinal substances is condensed in the lungs during the differential process by the compression consequent upon the commencement of the expiratory act This is impossible, first, because compression only acts to condense a saturated vapor, and the air passages cannot be saturated with the vapor of a medicinal substance, and secondly, because no greater compression is produced at the commencement of the expiration under the influence of differential pressure than under other circumstances Such compression as does occur is due to the resistance offered by friction of the bronchial tubes and by the narrow opening of the glottis, and it is impossible that these should be affected by the differential pressure

He believes that such benefit as results from the use of the cabinet is due mainly to the reduction of congestion in the lungs by the air pressure within them and by the increased expansion and movement of the lungs favoring their greater action and modifying their nutrition

---

Tuesday, May 11, Second Day

Morning Session

First Vice-President, Dr Frank Donaldson, of Baltimore, in the Chair

The report of the Committee on Health Resorts was received and ordered published in the Transactions

Dr Roland O Curtin, of Philadelphia, read a paper on

ROCKY MOUNTAIN FEVER

The speaker in the first place referred to a communication received from Dr D O Dougan, of Denver, Colorado, bearing upon this subject The experience of Dr Dougan had led him to regard all cases of mountain fever as belonging to one or another of the well known, already classified varieties The cases, however, present variations from the usual course of the fevers to which we would assign them Some of the cases are ephemeral in character and difficult of classification The fever especially designated by the name mountain fever presents many features of typhoid fever Some of the reasons for believing these cases to be an irregular or mild type of typhoid fever are that such cases are usually seen at the season of the year when typhoid fever is most prevalent, they occur most commonly under conditions favorable to the development of typhoid fever, not infrequently cases will present some characteristic feature of typhoid, leaving no doubt as to the diagnosis In the high altitudes where mountain fever is said to occur, a large proportion of the cases of undoubted typhoid pursue a remarkably mild course Dr Dougan concluded with a protest against admitting mountain fever as a specific disease, until its right to such a position had been proven by clinical and pathological researches

Dr Curtin had seen, in Wyoming Territory, four cases which had been diagnosed as mountain fever At some point in the disease, all these cases had diarrhœa, and in one it was continuous One of the patients died suddenly at the end of three weeks, but no autopsy was made, in one case there was a doubtful eruption, one of the cases had epistaxis in the beginning of the illness, tympanites was more or less marked in all cases Dr Curtin considered these cases to be typhoid or typho-malarial in character Sometimes the cases belonged, in all probability, to the class termed simple continued fever The diagnosis of mountain fever was doubtless, in large part, the result of incompetency on the part of the observers, and the use of the term is continued largely as a result of fashion

The opinion of other investigators was cited, all of whom expressed views similar to those given above

Dr C C Rice, of New York, read a paper entitled,

HOW THE THERAPEUTIC VALUE OF OUR MINERAL WATERS MAY BE INCREASED

The following conclusions were advanced

1 A physician should make an analysis of our mineral springs

2 The medicinal value of the waters should be tested by clinical investigation, and the conclusions published for the benefit of the profession

3 If the waters are found to present marked merit, the physician should interest himself in developing the springs, improving the baths, etc

4 Physicians, in sending patients to the springs, should be more careful to select the proper water, and should send with the patient the diagnosis and history of the condition for the benefit of the physician at the baths

5 The patient, while at the baths, should be under a more rigid medical discipline

6 The social life of our watering places should be reorganized

The following papers, describing the climate of various places were then read

The Climate of Mexico, by Dr Didama, of Syracuse, *The Southern Adirondacks*, by Edward T Bruen, M D, of Philadelphia, *The Climate of El Paso, Texas*, by Dr E W Schauffler, of Kansas City, *Southern Pine Park, a New Health Resort in North Carolina*, by Dr A N Bell

AFTERNOON SESSION

The following were elected

OFFICERS FOR THE ENSUING YEAR

President—Dr Frank Donaldson, Baltimore

First Vice-President—Dr V Y Bowditch, Boston

Second Vice-President—Dr Roland G Curtin, Philadelphia

Secretary and Treasurer—Dr J B Walker, Philadelphia

Additional Member of Council—Dr F C Shattuck, Boston

Elected to Membership—Dr F Donaldson, Jr, Baltimore, Dr G R Butler, Brooklyn, Dr W Matthews, U S A, and Dr J H Musser, Philadelphia

The following memorial was presented by DR J EWING MEARS, Secretary of a Special Committee of the American Surgical Association, appointed to consider the proposition with reference to the establishment of a

CONGRESS OF AMERICAN PHYSICIANS AND SURGEONS

WASHINGTON, D C, April 30, 1886

To the President of the American Climatological Association

In view of the fact that there are a number of special medical organizations now in existence in the United States, each having for its aim and attainment the advancement of the special department of medicine for which it was organized, and since the members of said special societies are of the representative men of the profession in America, many of whom are, at the same time, fellows or members of several of these special societies, which double membership, if it may be so expressed, necessitates them—if desirous of attending two or more of the meetings of these societies the same year—to make as many separate trips from home and often with much loss of time to themselves and inconvenience to their patients Therefore, it appears necessary that some arrangement should be made with the different societies as to a uniform time and place of holding their sessions, so that those members who wish to attend the meetings of more than one association may be enabled to do so without useless expenditure of money or unnecessary loss of time

An extended correspondence, together with personal conference with many of the most prominent fellows of this and other of the associations, has disclosed the fact that there is a decided and growing inclination to unite the various societies into a common whole, whereby it would become a general organization, representative of the various special departments of the profession in America

The plan proposed and which is offered for consideration is to unite the following named associations into a Congress based upon the outlines which are now to be explained American Surgical Association, American Ophthalmological Association, American Otological Association, American Neurological Association, American Laryngological Association, American Gynæcological Association, American Dermatological Association, American Climatological Association, and American Clinical and Pathological Association These associations to be united under the name and style of "The Congress of American Physicians and Surgeons"

The plan of organization hereby submitted, and subject to any alterations or amendments which may be deemed wise and proper, is that each society will preserve its own name, constitution and by laws, *elect its own officers and fellows, hold* its own sessions apart from the others at the time and place of meeting, publish its own transactions, and do all other acts of which, by virtue of its constitution and by-laws, it has the inherent right to do, thus preserving its own autonomy

The Congress to be composed of these special societies when in convention, and its meetings to be held annually in the city of Washington—the most appropriate place for the assembling of such an organization The constitution and by laws of the Congress to be formed by a committee composed of a like number chosen from each separate society The opening session of each annual meeting of the Congress to be devoted to such general business as may pertain to the interest of the association as a whole The Congress to be presided over by a President, elected annually, and who shall deliver the opening address upon the first day of the session The manner of choosing the President to be as follows By a nominating committee composed of one member elected from each special association, or otherwise, as may be determined upon by the special society itself, this committee nominating one or more candidates for the office of President, whose election is to be by ballot on the last day of the annual session, and in a convention of all the societies assembled The Presidents of the special societies to become *ex officio* Vice-Presidents of the Congress Membership in the Congress to be acquired only by virtue of fellowship in one or another of the special associations Other officers of the Congress to be elected or appointed as may hereafter be determined upon by the associations in convention

These are the outlines of a union proposed for the consideration of the members of this Association, which, if it should meet their approval, can be submitted to the action of the societies which have been mentioned It was suggested that the Chair appoint a committee of five to bring the subject before the next special Association, which meets this spring or coming summer, and which, in the event of a concurrence of opinion on the part of said society, shall act in concord with their committee appointed to confer with the other societies, in the order of their meetings This enlarged committee to report at a convention of all the societies, which shall be requested to hold their next annual meetings at the same dates in the month of June, 1888, in the city of Washington

To avoid any confusion as to the time of next meeting, each society (this year) could adjourn to meet in June, 1888, leaving the date to be fixed by the enlarged committee after their work of conference had been finished, it then being only necessary to apprise the Secretaries of the respective associa tions, who will give notice to the various fellows and members

This proposition is the result of calm consideration, and has been approvingly endorsed by quite a number of the representative gentlemen of the profession, both in and out of this special Association

The plan proposed is simply to unite into one great body the already existing special societies, and it is proposed from the honest conviction that such a union will prove of inestimable benefit to them individually and collectively

The special committee appointed by the American Surgical Association to consider the above memorial, reported that it viewed with great satisfaction the perfection of a plan through which the meetings of the associations above named in the city of Washington at the same time of the year, may be accomplished, and the meeting of all the associations in general assembly on such days as may be determined, for the purpose of delivering of addresses upon general subjects in medicine, such meetings to be held without any formal organization through which the associations meeting would sacrifice their autonomy

To accomplish these purposes, the committee offers the following resolution

Resolved, That a committee of five Fellows of this Association be appointed, which shall be authorized to confer with committees of other associations interested in the adoption of a plan of a convention as hereinbefore stated, and report upon the same at the next meeting for the action of the Association

The resolution was adopted, and the following committee was appointed in accordance therewith

C H Mastin, M D, Mobile, Chairman
C T Parkes, M D, Chicago
J Ford Thompson, M D, Washington
N Senn, M D, Milwaukee
J Ewing Mears, M D, Philadelphia, Sec'y

The proposition was approved, and it was decided to appoint a committee* to be announced later in the day

Dr J H Musser, of Philadelphia, made some

SUGGESTIONS REGARDING THE PREVENTION OF PHTHISIS IN MILL HANDS

He said that it was rather to prevent that state of the system which often leads to phthisis, that he desired to make some suggestions The suggestions more particularly referred to factory laborers He showed that states of ill health were common in this class of artisans, and asserted that it was very largely due to an inadequate supply of food, which was improperly selected and prepared, and to carelessness in attention to digestion This cause obtained more largely than bad hygienic surroundings or than the occupation itself If this be true, the remedy proposed was to have the plan of the Willimantic Cotton Company used by all mill proprietors That company has proved by experience and careful calculation that it pays them in quality and quantity of work done to supply milk to their boys and bouillon to their women twice daily, and that the health of the operatives is promoted and their lives prolonged thereby Dr Musser trusted that the members of the Society could influence proprietors to adopt this plan, and thereby close one of the avenues to disease and death

Dr C L Dana, of New York, read a paper entitled

A STATISTICAL INQUIRY REGARDING THE RELATION OF HIGH ALTITUDES TO NERVOUS DISEASES

The speaker presented the results of inquiries made at his request of twelve physicians living in Colorado Springs, regarding the effects of high climates on the nervous system in health and disease The majority thought that chorea in children was more frequent there than in lower altitudes, that the climate was bad for nervous women The high altitudes do not necessarily injure epileptics, and in anæmic cases might cause improvement Insomnia dependent upon anæmia and mal-nutrition was benefited and generally cured The climate has no specific influence for good upon diseases of the spinal cord, and if anything, the contrary The speaker was of the opinion that high altitudes had a tendency to excite lithæmia and anthritism with consequent irritating effects upon the nerve centres The best effects of the climate were seen in anæmic insomnia, neurasthenia and melancholia

The President announced as the committee to confer with the committees of other special societies with reference to the establishment of a "Congress of American Physicians and Surgeons," Dr A L Loomis, New York, Dr F Donaldson, Baltimore, Dr F C Shattuck, Boston, Dr E T Bruen, Philadelphia, and Dr W W Johnson, Washington

It was resolved to appoint a committee of three, with Dr C C Rice as chairman, to investigate *The Therapeutical Properties of the Different Mineral Springs*

After passing a vote of thanks to the College of Physicians for the use of their hall, the Society adjourned *sine die*

SUFFOLK DISTRICT MEDICAL SOCIETY

SECTION FOR CLINICAL MEDICINE, PATHOLOGY AND HYGIENE

Stated Meeting, April 14, 1886

F I Knight, M D, Chairman

Albert N Blodgett, M D, Secretary

Dr J W Farlow exhibited a girl aged 12 years, in whom was seen

A LARGE ARTERY PASSING IN A DIAGONAL DIRECTION ACROSS THE POSTERIOR WALL OF THE PHARYNX,

where its pulsations were plainly visible, and could be felt by the finger The vessel was of larger size than the radial artery in the same patient, and was covered only by the mucous membrane Dr Farlow described the condition of the parts in the following words

"The case is interesting on account of its extreme rarity, and because of its bearing on the surgery of the throat. It is a case in which we may see and feel a large pulsating artery on each side of the back of the pharynx, about a quarter of an inch inside of the posterior pillar of the fauces. In a service of several years in the throat-room of the Boston Dispensary, I have never met a case before. Dr. Knight remembers to have seen one similar case. During the week following the appearance of the present patient, another case was observed at the same institution, but in the second case the vessel was seen and felt on the right side only. It occupied, however, the same situation. Dr. Leland saw a single case at the dispensary, about a week later, which he kindly asked me to examine with him. I find the abnormal distribution of the large vessels of the pharynx hardly mentioned in works on diseases of the throat. In anatomical works, the possibility of variation in distribution of the vascular channels is alluded to in a cursory manner, but clinically very little has been said or written upon this subject.

"The vessels are usually deeply situated and quite small. The vessel in the left side in the present case feels considerably larger than the radial. In all surgical operations on the back of the pharynx, such as incision, or the application of the Galvano cautery, we may see at once how important it is to bear in mind the possibility of such a case as this, and to examine carefully as to the exact position of the blood-vessels. If the tonsillar branch were abnormally large, it would be sufficient to cause a very severe hæmorrhage after tonsillotomy, or deep incision, as in the case reported by Dr. Lefferts of New York, in which a vessel was cut by the guillotine, of so large a size as to require the application of a ligature, on account of the alarming hæmorrhage. Possibly in other cases of profuse bleeding after tonsillotomy, a similar condition of enlarged or abnormally situated vessels might be found."

Dr. W. N. Bullard then presented a girl aged 13 years, who was affected with

LUPUS ERYTHEMATOSUS.

The disease had existed one year, and was seated on the face and hands. The color of the skin in these parts was of a mottled hue, and on the face were a large number of small scars, which were somewhat below the level of the surrounding skin, and were of a dead white color. On the hands, which were similarly affected, the disease appeared as large elevated nodules of a livid color, and were confined principally to the extensor surfaces of the fingers, though the whole dorsum of each hand was of the same livid and mottled hue as the face. The disease extended only to a point just above the wrist, on each hand, where it abruptly terminated. The general health of the child was otherwise good.

Dr. White pronounced the case a typical one, but not so rare as has been supposed. The disease is much more common here than in Europe, but the small size of the present patient makes this instance seem more than usually interesting. The girl, however, is 13 years old, and after this age the appearance of this form of lupus is not so excessively rare. It is not frequently seen on the hands, but the co-existence of the same affection upon the face is very instructive as well as interesting. The disease is essentially an inflammatory process, confined to the sebaceous follicles.

DOMESTIC CORRESPONDENCE

LETTER FROM NEW YORK

(FROM OUR OWN CORRESPONDENT.)

Perityphlitis—Foreign Bodies in the Œsophagus—The New York Academy of Medicine.

At the meeting of the New York Surgical Society, of which a partial report was given in The Journal of May 15, Dr. H. B. Sands read some remarks on *Perityphlitis*. Within the last few months, he said, a number of cases of this affection had come under his observation, and they had had the effect of impressing very strongly upon his mind the necessity of absolute rest in its treatment. He could recall the case of a physician suffering from perityphlitis, who was doing fairly well, but who, while the disease was in progress, was allowed to take several doses of cathartic medicine, each of which only aggravated the trouble. Finally, after a copious passage, produced by an enema, he became collapsed, and death soon followed. The autopsy was made by Dr. George L. Peabody, but no cause was found for the existing perforation of the appendix. In this case it was evident that for a time the difficulty had been confined within quite narrow limits, and it could not be doubted that a better chance of recovery would have been afforded if the patient had been kept absolutely quiet, and opium given instead of cathartics.

The second case referred to was one which he saw in consultation with Dr. A. B. Ball. The patient was over 60 years of age, and Dr. Sands was called in because the symptoms were supposed to be those of strangulated hernia. It was true that he had a hernia on the right side, but the hernial sac was found so flaccid that the present trouble could not be attributed to this. The symptoms, also, were not exactly those of strangulated hernia. The case was in reality one of perityphlitis, but the patient was allowed to get up and go down town. The result was that peritonitis set in, and he died a short time afterwards. The post mortem examination showed perityphlitis, with perforation of the vermiform appendix, and an empty hernial sac on the right side. This case also, he thought, emphasized the importance of rest and opium in perityphlitis.

In one of the other cases narrated by Dr. Sands he said that for the first time in his experience he had met with the accident of cutting the intestine in an operation, and that this had occurred notwithstanding the fact that the hypodermic syringe was first resorted to, with the effect of withdrawing pus. When in operating the tumor had been arrived at, all who were present received the impression that a piece of intestine was being dealt with, and it seemed to him personally that there was a portion of the cœcum in the wound, instead of the usual abscess cavity. He made a cut with the scissors, and the impression conveyed to his mind was that he was cutting intestine From the opening there came pus and air, but no fæces The next day (Sunday), however, fæces made their appearance, and by Monday night they were flowing away in large quantity This free flow of fæces continued for about ten days, but at the end of a fortnight it had ceased altogether The patient got entirely well in three weeks Dr Sands thought that in this instance the hypodermic needle must have passed through both walls of the intestine before penetrating the abscess

The last two cases mentioned he had seen very recently One of them was that of a young lad, the son of a physician There were symptoms of peritonitis, in connection with perityphlitis, and after discussing the subject thoroughly with Dr Sands, the father declined to have an early operation performed The case went on pretty well for a week, but on the ninth day the patient became much worse There was subnormal temperature, distension of the abdomen, and vomiting, and the condition was in every way alarming He operated, in the usual way, April 24, and the abscess cavity was found to contain pus and fæces The patient, when last seen, was convalescent

In a case in which he operated on Sunday, April 25, the patient was a lad of 14 The first symptoms had appeared just a week before, and he first saw him on Wednesday, when he thought there were signs of perforation on the side of the peritoneum There was marked tympanites, and he was unable to make out the presence of a circumscribed tumor, although Dr A H Smith, who had been in attendance previously, said that he had discovered one when the abdomen was not so much distended Dr Sands saw the case again on Saturday, when the condition was found to be very bad As in the previous case, he debated very carefully whether to cut in the median line, or at the side, and thought it preferable to make the incision in the latter position Accordingly, he operated at 2 P M on Sunday, and when the layers of the abdomen were cut down upon, about half an ounce of pus was seen to flow from a small opening The abscess was doubtless in the cavity of the peritoneum, and the case, as had been suspected, was one in which perforation had taken place toward the serous membrane, and not one of perityphlitis amenable to the usual operation The patient died at 6 P M the same day

In closing Dr Sands said that he wished to call attention especially to the question whether in these cases laparotomy was preferable to the ordinary operation for perityphlitis When peritonitis had become general, laparotomy, in his opinion, offered no hope of saving life

Dr C K Bridden having remarked that he was inclined to doubt whether Dr Sands had in reality wounded the intestine in the case in which he believed this accident to have occurred (stating that if he had done so, he did not think that the patient would have recovered so readily), Dr Sands replied that it was quite possible to have a simple wound of the intestine, and have a rapid recovery also In illustration, he related a remarkable case of gunshot injuries of the intestines which had occurred in his own hospital experience

Dr A P Gerster presented a specimen which he thought constituted an interesting contribution to the subject of *Foreign Bodies in the Œsophagus* It was taken from a child 12 months old, in whom signs of respiratory difficulty, apparently in the larynx, first showed themselves at the age of 6 months About two months before Dr Gerster saw the infant a specialist in diseases of children was called in consultation, and made the diagnosis of a tumor, with a broad pedicle, in the larynx There was increasing difficulty in breathing, with occasional aggravated paroxysms, and when the case came under his observation, he found that there was frequent respiration, and that the dyspnœa was principally expiratory, there being but little difficulty in inspiration Owing to the paroxysms set up by the attempt to make a laryngoscopic examination, it was impossible to get a view of the parts Up to this time the general condition of the child had been good, but there was now considerable trouble in deglutition, and it began to fail appreciably The most careful inquiry failed to elicit the history of any foreign body having been swallowed In view of the increasing frequency of the attacks of suffocation, he advised an exploratory tracheotomy, to which the parents consented

On account of the extremely short and thick neck of the infant, he was obliged to select the higher operation, but when the trachea was opened, he was disappointed to find that there was not the slightest improvement in the respiration A soft catheter was introduced into the trachea and the branches, but no abnormality could be detected One very curious thing, however, was noticed When a canula was introduced into the trachea, the difficulty of respiration was increased, but as soon as he placed his finger over the mouth of the canula, the breathing became easier Fearing to keep the child, who was in very bad condition, longer under the influence of anæsthetics, he ordered the canula, with its orifice plugged, to be kept in position, his design being to keep the trachea open, and on a future occasion make a more careful examination The next day, however, pneumonia set in, and in three days death resulted

At the autopsy the larynx was found to be entirely normal, but a little lower than midway between the cricoid cartilage and the bifurcation of the trachea there was a triangular defect of the trachea, and as the seat of this defect the sharp edge of a metallic body projected into the trachea for about three millimetres The foreign body was a flat brass button, three quarters of an inch in diameter Corresponding to the defect in the trachea, was another defect in the œsophagus, circular in shape, and almost one centimetre in diameter The foreign body was imbedded in the tissues between the trachea and the œsophagus, being held in position precisely as a picture by its frame The ulcerative process had evidently been terminated by complete cicatrization No active inflammation was found in progress at the time of death, but the tissues were considerably thickened by former inflammatory processes

Dr Gerster said that among the questions which suggested themselves in connection with this case were the following How shall we explain the fact that there were no symptoms of any great dyspnœa at the time the foreign body was swallowed? Why is it that the symptoms of pronounced dyspnœa have developed so late? In answer to the second inquiry, he said that as time went on, the cicatricial contraction of the parts became greater, and thus the symptoms of dyspnœa and dysphagia became progressively aggravated Another question that might arise was, How shall we explain the difficulty of expiration, as contrasted with the comparative ease of inspiration? This, he believed, was on account of the position of the foreign body, which was oblique, and gave to it the action of a valve The stream of air rushing up from below had the effect of raising the projecting edge of the button, and thus placing it more transversely to the axis of the trachea The minute dimensions of an infantile trachea, still further reduced in this case by cicatricial contraction, would be influenced by very minute changes of position

As regards the question whether the foreign body could have been extracted, he felt constrained to express a negative opinion If, after tracheotomy, he had made use of a suitable probe, instead of the soft catheter, he would undoubtedly have detected the presence of the foreign body, but he doubted whether it could have been removed through the trachea without producing instant death from suffocation

Dr T M Markoe referred to a case recently reported by Bennett May, in which he successfully extracted a foreign body which had been in the œsophagus for three years, and had ulcerated partly into the trachea In answer to a question by Dr Gerster Dr Markoe stated that the child in this case was 7 years old, and that he fully appreciated the marked advantages which this more advanced age would give over the case of an infant such as Dr Gerster's patient

In reply to a question by Dr R F Weir, Dr Gerster said that he believed that an attempt to remove the foreign body would have proved fatal, because the diameter of the button was larger than the calibre of the trachea, and hence it would have completely plugged up the passage, and probably for a sufficiently long time, during the efforts at extraction, to cause suffocation

Dr Weir then said that he differed from Dr Gerster on this point, as in operations upon the throat he had more than once seen the trachea entirely occluded temporarily, in a digital exploration, without any serious result following He therefore thought that if the foreign body could have been seized, it might have been safely removed The risk of suffocation would come from the button slipping from the grasp of the forceps after it had been lifted out of its bed, but even then experience had already shown that such bodies often tilt sideways, so as to offer the least obstruction to air currents

That the position taken by your correspondent, that the New York Academy of Medicine, by the recent alterations which it has made in its constitution and by-laws, has completely deprived itself of the power of disciplining its members, is proved to be incontrovertible by the significant fact that at the stated meeting of the Academy held May 6, the following proposed amendment to Article VIII, Section 1, of the constitution, was introduced "The Academy may suspend or expel a Fellow for violation of its regulations, *or the commission of any act which unfavorably affects the character of the medical profession of the interests of the Academy*"

The incident related in a recent letter, however "unsavory" it may be, is not so "unauthenticated" as the *Medical Record* would have its readers believe, and it is a well known fact that the proposed amendment to the constitution is simply the sequel of the case referred to As to the facts of that case, as published, they were received directly from a prominent officer of the Academy, whose word no one acquainted with his standing would think of impeaching

P B P

MISCELLANEOUS

USE OF MICROSCOPE FOR DETECTING OTHER ANIMAL FATS IN BUTTER

[The following letter from DR THOMAS TAYLOR, of the U S Department of Agriculture, to the Editor of *Public Health in Minnesota*, is of sufficient interest to publish in full]

My Dear Sir —When I commenced microscopic observations of butter and fats, several years ago, it was with a firm conviction that I should be able to discriminate between pure dairy butter and oleomargerine by means of polarized light, basing my convictions on the fact that pure dairy butter is a non-polarizing substance, while the solid and semi fluid fats contained in such substances as lard and beef fat oil are polarizing bodies

When a specimen of butter like material is presented for testing, I mount about a grain of it upon a microscopic slide (a piece of glass 3 × 1 inch), over which I place a circular glass over, and compress the substance into a thin film, or until it appears semi-transparent If it presents a white, even, cloud like appearance, and has the odor and taste of butter, I conclude that it is probably butter If when boiled over the flame of a spirit-lamp, it gives off the odor of butter, I consider this an indication in its favor If when triturated with a few drops of strong sulphuric acid, it slowly becomes of a pale salmon color, within five to twenty minutes, or of a light brick red, changing after the lapse of about twenty-four hours to a tallow color, this is another indication of its genuineness Lard and beef fat, in the same length of time and under similar conditions, each assume a walnut color (For a fuller explanation of my acid test, see my first paper on the acid treatment of butter and fats)

If the sample is submitted to the action of polarized light and selenite plate, and appears of a uniform green, red, blue, or yellow color, according to the selenite used, we have another indication that the substance is pure butter , normal butter, under these conditions, never exhibits prismatic colors

Sometimes large crystals of salt cause the appearance of prismatic colors by refraction These should be removed Butter that has been exposed to the light until it is bleached, or butter that has been in immediate contact for a long time with a substance that absorbs its oil, as when placed in wooden tubs, has undergone a chemical change, and should not be considered as normal butter A superior butter when boiled with or without oil, will yield large crystals of fat by attending to the following directions Place from half an ounce to an ounce of butter in a test tube of sufficient capacity, holding the tube by means of a twisted wire over a spirit lamp, until the butter is thoroughly boiled for about one minute, then, in order to crystalize, let it cool in an atmosphere of 50 to 60 degrees F, during a space of from 12 to 24 hours, so that it will crystallize slowly this will give the best results Take a portion of this, when cooled, on the point of a pen-knife, place it on a glass slide, add to it one drop of sweet oil, and, with a pin, separate the crystals, which are large enough to be seen with the naked eye Subject the specimen to polarized light, turn the polarizer until a dark ground is produced, and the butter crystal will appear bright, exhibiting upon its surface a black cross, in outline the same as that known as the cross of St Andrew

When old butter, or butter which has been kept in a warm atmosphere, is boiled and cooled, a secondary crystallization quickly takes place, of rosette like form, which generally proceeds from the center of the cross A very superior, freshly made butter, rich in fats, which has been kept cool previous to re-boiling, map be preserved a long time at a temperature of 60 degrees, without exhibiting the rosette crystals, some of which may be observed in the act of "budding," the interspaces filled with the rosettes which have floated off from the original globose forms which show the black cross These appearances are among the conditions which distinguish pure butter from the fats of beef mutton and lard Use a magnifying power of about 250 diameters for the small rosette like bodies, which vary greatly in size, and might be mistaken by an inexperienced observer for the crystals of the fat of beef, in their early stage of development

Beef Fat—Take any portion of beef fat, render it slowly in an iron pot without water, strain it and set it away to cool To an ounce of solid fat thus obtained, add cotton seed oil, heat in a test-tube nearly to the point of decomposition, and let it cool for about 24 hours at a temperature of about 60 degrees, F Its consistency should then be semi fluid The crystals of the fat of beef are very small on first boiling and should be reboiled and cooled several times In this way the crystals enlarge and become better defined, and appear quite different from the secondary crystals of butter High powers are required for this fat, say from 450 to 1000 diameters The crystals of beef fat treated as above, and viewed under high powers, present a foliated appearance In my ordinary methods of mounting for temporary use, I take care to press the covers very gently, especially when mounting large crystals of butter Beef, mutton and lard may be pressed without damage

Lard—No reliance can be placed upon the lards of commerce as to their purity Leaf lard is now rendered by some firms with a small quantity of soda for the purpose of dissolving the tissues, by this means an impure lard is produced, which contains a small amount of soap in which the crystals are not so well defined as in lards rendered without the aid of chemicals

Lard composed of stearine and cotton seed oil is also in the market, it may contain beef fat, for one of the forms of stearine is a roughly made by product of the oil of beef fat A lard thus made will show strongly marked stellar crystals To avoid mistakes in regard to the crystallography of the fats of plants and animals, I always render the fats I use in my experiments, noting the stages of crystallization through which they pass in oil solutions

Having noted some of the peculiarities of normal butter, the crystalline character of boiled butter, of lard, and of tallow, one is in a position to discriminate between pure normal butter and the butter substitutes containing free fats That pure dairy butter viewed under polarized light and selenite plate, shows no prismatic colors, the following experiments demonstrate Place a green selenite between the polarizer and the analyzer and a plain green color will be observed Then place a mounted slide of normal butter under the selenite, view again, and the same even green color is observed Now, place a small portion of lard and beef fat oil on the slide, and with polarized light and the same green selenite, the fat will exhibit prismatic colors, showing the contrast between a polarizing body, such as the semi-solid fats, and a non-polarizing body like pure dairy butter

Butter and oleomargarine—The preceding experiments explain why butterine, which contains solid or semi fluid translucent fats, such as lard and tallow, in combination with unboiled butter, is so easily detected when submitted to the action of solarized light and selenite plate The crystals of lard or of tallow are seldom absent, and are easily distinguished from the mass of amorphous fats with which they are combined This is one of the most important of all my tests of oleomargarine and butterine

Prof H A Weber, of the Ohio Experiment Station, reports in Bulletin 13 of that Station, under date of March 1, 1886, that by the use of my butter tests on a variety of butters procured from those on exhibition at the Stock Show at Chicago, he observed invariably the form of the St Andrew's cross, as I have described it, and further, that on submitting lard to polarized light, "nothing but the small irregular stellated bodies could be seen, in which cross was entirely wanting A large number of slides were mounted and examined, but not a single 'butter crystal' could be found" Prof Weber further states that "oleo oil" (beef-fat oil), treated in a like manner, gave similar results, "only small stellate crystals were present Thus far the results and statements of Dr Taylor were fully corroborated" He thus acknowledges the correctness of three of my original experiments, but fails to apply them in practice According to his report he made fifteen experiments in all, of these only the first three have any relations with my methods, the remaining twelve are based on his uniform plan of boiling all of his combinations of butterine at a high temperature

I have just examined a composition of butter and "oleo oil" (beef fat oil), in the proportions given above The butter was melted at a temperature of 104° F, and combined with the beef-fat oil The mounted slide did not show any butter crystals, while it did exhibit those of beef, (oleo oil) In this case the methods of those engaged in the production of butterine and oleomargarine, were imitated by only melting the butter and fats at a very low temperature Prof Weber erred in boiling his oleomargarine, and this holds good with all his experiments, from four to fifteen inclusive His last twelve experiments must be eliminated from our consideration of this subject, because they have no relation to my methods of discriminating between butter and oleomargarine, nor has the black cross of boiled butter any direct relation to this subject, since dairy butter is not sold in the markets in a boiled condition It is only when the differentiation of the respective crystals of the fats of the various plants and animals is considered, that the cross of butter becomes an important factor

Prof Weber's experiments, wherein by triturating lard and oleo oil with a little salt and water, he forms globular fatty bodies, which exhibit a cross like that of butter, affords an interesting confirmation of my statement to the Commissioner of Agriculture, see the annual report for 1885, wherein I say, that any body which is globular, translucent, smooth and polarizing, will show a cross (See also the Annual Report of the American Society of Microscopists for same year)

That which Prof Weber terms fat "globule," is such a body as I described, "globular, translucent, smooth and polarizing" Polarizing, because it contains semi-solid, translucent fats Had Prof Weber examined such globules by plain transmitted light, he would have discovered that they have no resemblance to the globose butter crystal viewed under the same conditions, which has a uniform structure peculiar to itself (See figure 2, of the abstract of my paper on Butter and Fats, read before the American Association for the Advancement of Science, last September)

In an experiment made as late as the 20th of this month, in the presence of Prof Wiley, Chief Chemist of the Department of Agriculture, and two of his assistants, Mr Richardson and Mr Richards, I demonstrated that a butterine made at my request in the Laboratory, which contained but *1 per cent lard to 99 per cent pure butter*, exhibited, when examined by polarized light and green selenite, well defined crystals of lard, of a rich golden color on a green ground, the green representing the butter In this way the adulteration was at once detected

The experiments of Prof Weber are calculated to introduce confusion and difficulty into a matter in itself comparatively clear and easy The problem which has engaged his attention seems not to have been how to discriminate between butter and its substitutes, but how to subject them to conditions which, as far as possible should render them indistinguishable It must be borne in mind that the manufacturers of counterfeit butter are obliged to limit their treatment of the substances they use to such manipulations as are consistent with the salability of the product

Ohio State Medical Society —The forty first annual meeting of this Society will be held at Akron, Ohio, on June 2, 3, and 4, 1885, under the Presidency of Wm Morrow Beach, M D The list of papers is very large and unusually promising Delegates and members should procure railway certificates from the Secretary, G A Collamore, M D, of Toledo, before leaving home, specifying the route chosen

A New Work on Renal Diseases —A forthcoming work on "Bright's Disease and Allied Affections," by Dr Charles W Purdy, of Chicago, is announced by Lea Brothers & Co It will be published simultaneously by H K Lewis, of London

Chicago Medico Legal Society —This Society, which has been recently formed in this City, has for its object the investigation, study and advancement of the science of medical jurisprudence, the punishment of unprofessional and criminal practices by members of the medical and legal professions, the prevention of blackmailing, and the procuring of such legislation as may be necessary to these ends Applications for membership should be addressed to the Executive Committee, through the Secretary, Marshall D Ewell, M D, 170 Washington St, and should be accompanied by $5 00, which will be returned if the applicant be rejected Any regular practitioner of medicine or lawyer in good standing may, upon recommendation of the Executive Committee, become a member

---

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY, FROM MAY 8 1886 TO MAY 14 1886

Major David L Huntington, Surgeon, ordered to proceed from Washington to Davis's Island, New York Harbor, on public business connected with the reconstruction of the present hospital building at that depot, or the erection of a new one On completion of this duty to rejoin his station (S O 109, A G O, May 10, 1886)

Major Henry R Tilton, Surgeon, from Dept East to Dept Cal

Major John Brooks Surgeon, from Dept Cal to Dept East

Capt Edward T Comegys, Asst Surgeon, from Dept Mo to Dept East

Capt Aaron H Appel, Asst Surgeon, from Dept East to Dept Mo (S O 106, A G O, May 6, 1886)

Cap James A Finley, Asst Surgeon, ordered for duty at Ft Buford, D T (S O 39, Dept Dak, May 5, 1886)

Capt R B Benham, Asst Surgeon, ordered to Dept of the Platte (S O 109, A G O, May 10, 1886,)

Capt A V Cherbonnier, Medical Storekeeper, U S Army, granted leave of absence for four months, with permission to apply for four months' extension (S O *109*, A G O, May 10, 1886)

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U S NAVY DURING THE WEEK ENDING MAY 15 1886

Bransford, J F, Surgeon, invalided home from Pacific Station

Winslow, Geo F, Surgeon, ordered June 1 prox to the U S S "Atlanta"

Heffinger, A C, P A Surgeon, detached from the Navy Yard, Portsmouth, N H, and ordered to U S S "Atlanta" June 1

ADDRESS IN SURGERY

THE PRESENT STATUS OF ABDOMINAL SURGERY

Delivered at the Thirty Seventh Annual Meeting of the American Medical Association on Tuesday, May 5, 1886

BY N SENN, M D ,

OF MILWAUKEE WIS

CHAIRMAN OF THE SURGICAL SECTION OF THE AMERICAN MEDICAL ASSOCIATION FOR 1886

The frequency with which grave complications followed even the most trivial operations before the introduction of the modern treatment of wounds, undoubtedly induced the great Hunter to remark "The necessity for operation is in truth the defect of surgery " To day, with an improved technique and the means at our disposal which, if properly applied, will furnish almost absolute protection against wound infective diseases, the surgeon can, with a just source of pride and gratification, confirm the correctness of the assertion made centuries ago by Celsus, "*quæ manu potissimum curat*"

No one who is familiar with the medical literature of the last two decades can arrive at any other conclusion than that the legitimate sphere of the physician has been gradually growing smaller, or, if this statement be objected to, that the practice of medicine has become more and more surgical In accordance with the spirit of the times, uncertainty and doubt in the diagnosis and treatment of disease must give way to positive knowledge and actual demonstration Surgery has gained the supremacy over medicine because the principles upon which modern surgery rests have been made the subject of accurate investigation and positive demonstration in the chemical, physiological and pathological laboratories

The science of surgery is rapidly assuming a degree of accuracy approaching in perfection any of the exact sciences During the last few years surgery has assumed a decidedly progressive and aggressive character Operations which a few years ago would have been deemed impossible or unjustifiable, have become established, legitimate surgical procedures In obscure doubtful cases the scalpel is now frequently resorted to, without fear of causing additional complications, for the purpose of making *intra vitam* an anatomical diagnosis Modern surgery has achieved its greatest triumphs in enlarging the field for the direct local treatment of disease, thus enabling the surgeon to treat with success injuries and lesions beyond the reach of medicinal agents The surgical literature of the day bears abundant evidence that the remotest organs are now approached by the surgeon with comparative immunity, and that incalculable benefit has been derived from direct operative treatment The affections of abdominal organs have received the well merited attention of surgeons since the improved wound treatment has been introduced Numerous maladies which heretofore have been considered incurable are now successfully treated by the surgeon by operative measures Experimental research and clinical experience have demonstrated that organs and parts of organs which were heretofore regarded as indispensable and essential, can be successfully extirpated when they are the seat of injury or disease With a view of directing your attention to a few of the most brilliant achievements of modern surgery, I have selected as the subject of my address, 'The Present Status of Abdominal Surgery " A condensed brief account of the more recent advances made in the surgical treatment of injuries and diseases of the abdominal organs must interest equally the physician and the surgeon

It is not my intention to trespass upon the legitimate field occupied by the ovariotomist or the gynecologist I shall therefore limit my remarks to a consideration of such injuries and lesions of the abdominal organs as they present themselves to the physician and general surgeon It will be my special aim to point out the limitation of abdominal operations, and to draw a distinct line between the feasibility and justifiability of such operations

I *Penetrating Wounds of the Abdomen* —During the last year the literature on this subject has been enriched by two valuable papers by Drs Dennis and Bryant, of New York These contributions, made in such rapid succession, may be considered as sufficient evidence of the deep interest which has been awakened among American surgeons on this practical and important subject

Dennis has well said, "It is a source of National pride that laparotomy in penetrating wounds and visceral injuries of the abdomen was conceived, developed and perfected in America."

The propriety of resorting to abdominal section in every case of penetrating wound of the abdomen is urged by many, but it cannot be said that this practice is sanctioned by the majority of the profession at the present time The great difficulty that presents itself to the surgeon in the absence of positive symptoms, is to differentiate between a penetrating and a visceral wound Clinical experience and statistics have demonstrated the importance of making a distinction between punctured wounds and gunshot wounds of the abdomen both in reference to diagnosis and treatment It is well known that penetrating stab wounds are less likely to be complicated by visceral injury than bullet wounds, consequently this class of injuries offers a more favorable prognosis and does not call so uniformly for treatment by abdominal section As in stab wounds, there is a greater tendency to prolapse of the intestine, exploratory laparotomy for diagnostic purposes is also less frequently called for The numberless recoveries after stab wounds of the abdomen, without resorting to heroic treatment, must induce every thoughtful surgeon to abstain from subjecting the patient to the additional risks of laparotomy, unless the symptoms are such that the existence of visceral injury can be assumed with a reasonable degree of certainty It must, however, be remembered in arriving at conclusions concerning the nature of the injury, that the symptoms do not always correspond to the gravity of the visceral lesion, hence if any doubt remains in the mind of the surgeon, it is justifiable and proper, now that exploratory laparotomy can be made with such comparative immunity, to resort to it and give the patient the only chance of recovery by ascertaining the exact nature of the injury, which can be the only proper and safe guide to rational and successful surgical treatment Dr Dennis has called special attention to volvulus as another complication of stab wounds of the abdomen, a condition which, when present, would in itself always indicate an abdominal section for its relief In doubtful cases exploratory laparotomy can be done by enlarging the wound, which, when required, can be followed by the usual incision in the median line when operative treatment of the visceral lesion is required

In gunshot wounds of the abdomen the course of treatment to be pursued is more definitely settled by accumulated knowledge resulting from careful experimental research and an immense clinical material These injuries are so uniformly fatal that the slightest suspicion of injury of the intestine calls for treatment by laparotomy as affording the only chance of recovery for the patient The statement by Otis that gunshot injuries of the small intestines are always fatal if treated upon conservative principles, is practically well established, and is a sufficient argument in favor of treatment by abdominal section In penetrating gunshot wounds it is highly probable that visceral injury exists, and this fact constitutes a potent argument in favor of surgical interference, which alone is adequate to prevent an inevitable fatal termination The brilliant results which have been obtained by Bull, Hamilton, and others in desperate cases of multiple perforations of intestines, by operative treatment, afford abundant encouragement for imitation of their practice

It can be justly said that the surgeon who allows a patient *to die from* the effect of a visceral injury of the abdomen produced by a stab wound or a bullet wound, without at least a proposition to resort to abdominal section, has failed to discharge the duties imposed by the teachings of modern surgery Difficulties may be encountered by the medico legal bearing of a case, but when called upon to treat an otherwise fatal injury, this should not deter the surgeon to resort to the only measure which might save a human life The first indication that presents itself in the treatment of an open wound of the peritoneal cavity is to prevent infection by covering the wound with an antiseptic compress, until ample preparations can be made for more effective treatment Whenever practical, the necessary dressing or operation should be done with the least possible delay and at or as near as possible the place where the injury was inflicted Procrastination and transportation are dangerous factors in the treatment of this class of injuries, as both augment the gravity of the case by increasing the danger arising from the two most dangerous conditions—hæmorrhage and fæcal extravasation

The preparation for an abdominal section should be made with the same care as in opening the abdomen for the removal of an ovarian tumor If the operation has to be performed we can never rely on an aseptic atmosphere, hence the minutest details of antiseptic surgery must be followed The wound and especially the prolapsed viscera must be kept protected as much as possible against the air by avoiding unnecessary exposure

As a disinfectant solution corrosive sublimate should be preferred to carbolic acid The temperature of the room should be kept at 80–90° F Until the abdominal cavity is opened the field of operation must be frequently irrigated The intestines when brought out of the wound should be carefully protected with a warm aseptic compress kept moist with a weak solution of corrosive sublimate with a view of preventing abstraction of heat and guarding against infection

The abdominal section has for its object 1 Positive diagnosis 2 Arrest of hæmorrhage 3 Restoration of a breach of continuity 4 Removal of extravasation Exploration of a penetrating wound either with the finger or a probe is never justifiable as it increases the danger from extravasation and hæmorrhage without furnishing any information of a diagnostic value The direction of the wound canal and the anatomical location of the different viscera must be carefully considered before resorting to operative measures

When it becomes necessary to make an exploratory incision of sufficient size to enable the operator to introduce his hand it is preferable to select the median line, as an incision at this point inflicts less additional traumatism, is attended by little or no hæmorrhage, and can be utilized at once for the necessary operative treatment of the visceral lesions, if they exist It is a source of comfort to the surgeon to know that the different operators experienced but little difficulty in detecting the seat of lesion in the bowel, and that usually all the perforations were found in multiple wounds of the intestines It is unnecessary to urge upon you the importance of a careful search for additional injury when one perforation is found, as a failure to detect all of the openings in the intestine would frustrate the object for which the patient was subjected to such a grave procedure

Great stress has been placed upon the importance of carefully arresting all hæmorrhage From the peculiar anatomical relations of the blood vessels in the abdominal cavity it has been found that even very small vessels will continue to bleed unless permanent hæmostatic measures are employed If many bleeding points are encountered a number of hæmostatic forceps can be applied before tying the vessels If any of the large venous trunks have been injured, peripheral venous compression will facilitate the difficult task of securing the bleeding vessel If the wound in the bowel can be approximated without producing too much narrowing of its lumen it should be closed with a Lembert's or a Czerny Lembert's suture

If enterectomy becomes necessary the two ends of the bowel should always be united with a Czerny-Lembert's suture, as this suture secures accurate approximation of an extensive serous surface, and thus furnishes the most favorable condition for rapid union which affords the best possible protection against the danger of subsequent extravasation If fæcal extravasation has taken place it becomes necessary to resort to a careful toilet of the peritoneum, which can be accomplished most efficiently with large flat aseptic sponges wrung out in a weak solution of sublimate When extensive soiling of the peritoneal cavity has taken place it would appear most expedient to resort to thorough irrigation with warm sterilized water, with a view of effecting mechanical removal of all foreign substances When this has been accomplished the peritoneal cavity should be further cleansed and dried with a sponge wrung out of a $\frac{1}{20}$ per cent solution of corrosive sublimate The abdominal incision is closed in the same manner as after abdominal section for other purposes, in all cases where we have reasonable cause to believe that we have succeeded in securing an aseptic condition of the peritoneal cavity, if any doubt remains upon this point, drainage is indicated

The subsequent treatment must be conducted on general principles, rest, absolute diet, and the administration of opium being the most essential conditions in favoring rapid healing of the the intestinal wound In the future shock will not be mentioned as frequently as heretofore as a cause of death in penetrating wounds of the abdomen, as it has only too frequently been mistaken for the symptoms due to acute anæmic from hæmorrhage into the peritoneal cavity Further, when life is threatened from this cause, a fatal termination can often be prevented by resorting promptly to transfusion of blood, or infundation of a saline solution, after the bleeding points have been secured I am satisfied that no modern surgeon would hesitate to endorse the treatment of visceral wounds of the intestines by abdominal section, the opposition to the operation can only be entertained in cases where it is impossible without an exploratory incision to differentiate between a penetrating wound and a visceral wound

It is to be regretted that in perforating wounds of the intestines symptoms are often deceptive, and cannot always be relied upon as an unerring guide in diagnosis Grave symptoms may be almost entirely absent, and yet many perforations exist, while in other instances severe symptoms may be present without visceral injury Until we shall be able to make a differential diagnosis by the simple interpretation of symptoms, we must insist upon the justifiability of explorative laparotomy for diagnostic purposes in all doubtful cases, and upon the importance of treating all visceral wounds of the intestines by abdominal section, as affording the only chance of preventing an otherwise almost certain fatal termination

II *Laparo Colotomy*—In cases of rectal cancer not amenable to extirpation, Madelung advises that the colon should be divided completely across low down, and the peripheral end should be permanently closed by inverting the margins deeply and applying two rows of sutures A preternatural anus is established by stitching the proximal end to the margins of the wound in the same manner as in forming an intestinal fistula in any other locality The advantages of this operation over the ordinary method are twofold 1 The disease in the lower end of the bowel is not aggravated by the coming in contact with the intestinal contents 2 No fecal accumulation takes place below the artificial opening as is so often the case after the ordinary methods of colotomy Pollsson and Letievant advise the same operation

III *Subcutaneous Laceration of Intestines*—One of the darkest chapters in abdominal surgery pertains to subcutaneous traumatic rupture of the intestines That this accident occurs more frequently than has been generally supposed is well substantiated by recent investigations, and as the majority of cases have proved fatal on the expectant treatment, it is proper and important to consider the propriety of abdominal section in all cases where we have reason to suspect its existence

Muguier has called attention to the fact that in some instances, the laceration may be incomplete and give rise to no serious symptoms for days or weeks, until perforation takes place A contusion of the abdomen is received and the patient and surgeon are in the belief that no serious injury has been sustained until symptoms indicative of perforation, and fæcal extravasation announce the gravity of the primary lesion He reports three cases of this kind which came under his own observation, only one of which terminated favorably, and in this case the perforation produced a suppurative perityphlitis He cites four additional cases, of which two terminated in recovery after the formation of a fæcal abscess These cases should at least put us upon our guard to exercise proper care in the treatment of abdominal contusions, so as to prevent, if possible, the disastrous consequences incident to perforation Regulation of diet, rest, and the use of opiates may do a great deal towards the restoration of a partial loss of continuity of the injured bowel

Chavasse observed two cases of laceration of the intestine from contusion of the abdomen which induced him to compile all cases of rupture of the intestines due to the same cause He found a record of 149 such cases A careful study of this material led him to the conclusion, that in almost every case laceration or crushing of the intestine takes place at a point between the place where the external violence is applied and the unyielding resistence offered by the posterior abdominal wall Of these cases only six recovered, while the remaining number usually died within twenty four hours with symptoms of perforative peritonitis He is in favor of treatment by abdominal section, with a view of suturing the torn intestine or making an artificial anus

Berger insists that laparotomy should be performed in all cases where a diagnosis of intestinal rupture can be made In the differential diagnosis injury to the kidney becomes apparent from the character of the urine Injury to the gall bladder can be excluded if the patient throws up large quantities of bile The direction and amount of force which produced the injury as well as the extent of surface which was exposed to the violence, must also enter into consideration in determining the location and extent of the visceral injury In contra distinction to injury of the liver and spleen, rupture of the intestine must be suspected in case the force is applied over the median line, anteriorly, forcing the intestines directly against the spinal column Berger and Verneuil speak against primary resection and suturing in these cases, and advise the formation of an artificial anus The great difficulty which presents itself to the surgeon is the absence of positive diagnostic symptoms

In a recent paper on this subject Dr Weir enumerates as the most prominent symptoms collapse, rapid respiration, frequent wiry pulse, vomiting thoracic respiration, emphysema, and absence of hepatic dulness The last symptom, when present is one of the most certain signs indicative of the existence of perforation, but it is also necessarily absent in all cases where the liver has become fixed and immovable by inflammatory adhesions prior to the accident Emphysema and collapse are the two most constant and reliable symptoms upon which to base a probable diagnosis soon after the accident has occured Extensive extravasation usually does not take place, as the experiments of Jobert upon dogs have shown, that if the intestine is completely divided, the ends may contract by their circular fibres, and thus prevent escape of the intestinal contents Of all the cases so far reported, the rupture was found almost uniformly in the small intestines and in preference in the first portion of the tract, the duodenum and the jejunum, an important hint in searching for the seat of laceration on making abdominal section The shock attendant upon this accident is more apparent than real, and is in no ratio to the gravity of the injury It must also be remembered that hæmorrhage is an important element of danger, and, when considerable, it may simulate the existence of shock So far the only case on record where laparotomy was performed for traumatic laceration of intestines is reported by Mr Owens, of London, who found the laceration, sutured and returned the bowel Unfortunately the patient died Duplay affirms that the rupture, as a rule, is complete, and as such an accident must be uniformly fatal, abdominal section affords the only chance for the recovery of the patient and should always be resorted to whenever the history of the case and the symptoms presented indicate the presence of this lesion As the intestinal coats have undergone no pathological alterations, typical circular resection and suturing of the bowel should be practised in preference to the advise given by Chavasse, Berger, and Verneuil of establishing an intestinal fistula

IV *Intestinal Obstruction* —The treatment of intestinal obstruction by abdominal section is still in its infancy, but in view of the almost hopeless condition of patients suffering from obstruction due to permanent organic changes, the results which have been obtained by operative procedures should stimulate us to abandon the expectant treatment for more positive measures Schramm has collected 190 cases of intestinal strangulation treated by laparotomy, including three cases observed by himself in the practice of Mikulicz He alludes to the difficulties encountered in the diagnosis of these cases and pleads in favor of early operative interference Of this number 64 2 per cent died, the mortality before the antiseptic treatment of wounds being 73 per cent, and since that time 58 per cent The cause of strangulation and mortality attending each kind may be gleaned from the following table

27	times,	Invagination,	8	cured,	19	died
49	"	Bands or intestinal diverticulum,	13	"	36	"
16	"	Adhesions,	7	"	9	"
11	"	Reduction *en masse*,	6	"	5	"
10	"	Torsions,	1	"	9	"
12	"	Knotting of bowel,	4	"	8	"
12	"	Internal strangulation,	4	"	8	"
7	"	Foreign bodies,	4	"	3	"
38	"	Neoplasms,	16	"	22	"
8	"	Unknown causes,	5	"	3	"

The results of operations for internal strangulation will improve as soon as the physician will recognize the inefficiency of the expectant plan of treatment and will resort to timely operative measures, before the strength of the patient has been exhausted, or the cause of strangulation has led to extensive secondary pathological changes in the tissues about the seat of strangulation Recently Kussmaul has introduced irrigation of the stomach as a means of treating intestinal obstruction While this measure does not exert any positive curative effect upon the cause of obstruction, it serves as an efficient palliative by diminishing hydrostatic pressure and subduing increased peristaltic action, conditions which necessarily aggravate the symptoms due to obstruction

a Intussusception —Until recently the operative treatment of invagination has been considered by the majority of the profession almost in the light of a criminal procedure At present the indications are that most surgeons would resort to it in all cases where severe symptoms are present which would indicate the existence of acute or chronic obstruction from this cause and not remediable by medical treatment or local measures In cases where no adhesions have taken place between the *intussusceptum* and the *intussuscipiens*, reposition can frequently be effected by the administration of an anæsthetic for the purpose of relieving abdominal tension, manual or instrumental attempts at reduction, inversion of the patient, forcible rectal injection of water, and massage over the invaginated bowel The injection should be made slowly and uninterruptedly until resistance is overcome, but also with sufficient care to prevent rupture of the bowel.

If these measures fail to effect a reduction no time should be lost in resorting to abdominal section with a view to facilitate disinvagination by direct manipulation. If by traction, direct compression, dilatation of neck of *intussuscipiens*, separation of adhesions, etc., reduction is not accomplished, circular resection of the invaginated bowel, or the formation of an artificial anus above the invagination present themselves as the only means to save life within the range of operative surgery. The formation of a preternatural anus is preferable in cases where a large portion of the bowel has become invaginated, and again where the general condition of the patient is so grave that the more severe operation of enterectomy is contraindicated. In fifty-one cases where laparotomy was done, reduction was successful in twenty-six—eighteen children with four recoveries, and eight adults with five recoveries. So far no child less than six months old has recovered after operation. In the twenty-five cases where reduction failed to be accomplished or where no attempt was made, in four the abdomen was closed without any further attempt being made; in all of them the result was fatal. Of eleven cases of resection only one recovered, and this was Czerny's case where the disinvaginated bowel was resected on acount of malignant disease. In nine cases enterotomy was performed, as reduction was found impossible, and circular resection was deemed impracticable; in all, except one, death occurred a few hours after the operation. In the latter case life was prolonged for two and one half days, the patient being an adult female.

So far success has attended abdominal section for invagination in cases where disinvagination by direct manipulation was accomplished, an experience which argues strongly in favor of an early operation before reduction is rendered impossible by additional pathological conditions. It may be stated as a rule that temporizing measures should not be relied upon for more than two days.

In the case of adults when chronic symptoms of obstruction precede an acute attack, the invagination is often due to the presence of a tumor upon the inner surface of the intestine, a condition so well illustrated by Czerny's cases reported by Fleiner. The first patient was 45 years of age where an adenocarcinoma of the ileo cæcal valve produced invagination of the lower portion of the ileum into the colon. The stenosis was partial and chronic, but when invagination occurred the symptoms of obstruction became sufficiently urgent to justify a resort to laparotomy, which was performed in the median line. The seat of obstruction was readily found and the invagination was corrected, but the patient died on the following day of peritonitis.

In the second case, a man 52 years of age, the symptoms of obstruction appeared suddenly. He recovered partially from this attack and came under Czerny's care six weeks after the acute attack. A tumor, freely movable, was found close under the right costal arch. The diagnosis was narrowed down to either a floating kidney with symptoms of strangulation or intussusception produced by a tumor of the intestine, with the probability in favor of the latter. Abdominal section revealed the correctness of the latter supposition. The ileum had slipped into the colon and had ascended as high as the right flexure of the colon. The invagination was reduced without difficulty. At the apex of the invaginated portion a carcinomatous tumor was found. The growth was excised with a broad healthy strip of the intestinal wall, and the wound sutured. The patient was discharged on the twenty-eighth day, and presented himself four months later in excellent health. That the prognosis would be more favorable if the invagination is caused by a benign tumor of the intestinal wall is apparent. If in such cases disinvagination is possible an incision into the bowel will enable the surgeon to remove the tumor either without or only with partial resection of the intestine, and the operation is finished by closing the wound with a Lembert's or Czerny-Lembert's suture.

b. Enterolithiasis.—The subject of intestinal obstruction by an enterolith has been prominently brought to the attention of the profession by two cases reported during the last year by Dr. Lange and Dr. Beam. Dr. Lange's patient was a woman 60 years of age who had for a year suffered at times from colicky pains which were attributed at the time to the passage of gall stones. She was suddenly attacked with symptoms of acute intestinal obstruction, and when visited by the doctor four days later she was in a condition of collapse. As an operation offered the only possible chance of recovery median laparotomy was performed. On opening the peritoneal cavity a considerable quantity of turbid flocculent serum escaped, and after the omentum had been lifted the small intestine presented itself, moderately distended and matted together by recent adhesions. Tracing the distended bowel, in a few seconds a hard lump was felt in the interior of the intestine, below which the bowel was entirely collapsed. It was evident that the obstruction was caused by this foreign body, which was removed through a longitudinal incision in the bowel. The intestinal wound was closed with a double row of sutures and the abdominal incision united in the usual way. The patient died eight hours after the operation. The mass removed was sufficiently large to occupy the entire lumen of the intestine, and on section showed in its centre a crystalline round nucleus of cholesterin, about the size of a small walnut, around which, in concentric layers, was a brownish crust varying in thickness from one fourth to one-half centimetre. The concretion had undoubtedly formed during the passage of the gall stone.

An enterolith of similar size and structure has been recently shown me by Dr. Ira Manley, of Markesan, Wisconsin, which he removed post mortem from the lower portion of the small intestine in a woman who had suffered a long time from intestinal obstruction which finally proved fatal.

In Dr. Beam's case the enterolith had become arrested in the ileum just above the ileo cæcal valve, where it gave rise to acute obstruction. Laparo-enterotomy was performed and the patient recovered The foreign body was as large as an English walnut and contained a nucleus as large as a buckshot

As in most specimens heretofore examined the nucleus of the enterolith was composed of a gall stone, the previous history of gall stones should be remembered in considering the nature of the cause of the obstruction, and when a probable diagnosis can be made an operation should not be delayed, as the foreign body may also give rise to perforation

c Entero stenosis —Non malignant cicatricial stenosis of the intestine as a cause of intestinal obstruction, if circumscribed and not multiple, offers one of the most favorable conditions for operative interference In cases of this kind the intestine on the proximal side of the stricture will be found enormously dilated, and this condition will greatly facilitate the detection of the seat of obstruction Typical circular resection should be performed, as it is the only measure which promises a permanent recovery Intestinal stenosis due to malignant disease calls for enterectomy or enterotomy according to the extent of the disease, the condition of the adjacent organs, and the general condition of the patient

d Internal Strangulation —The remaining causes of obstruction, included under the common term "internal strangulation," comprising volvulus, torsion, internal hernia, and strangulation by bands of cicatricial tissue, are the cases which have yielded such a large mortality after abdominal section simply because the operation was delayed for too long a time These cases, when treated by timely interference, ought to furnish the most favorable conditions for abdominal section, as many post-mortem examinations have shown that a slight interference might have saved the patients' lives The existence of intestinal obstruction, acute and chronic, is characterized by a familiar complexus of symptoms, so that *the condition is readily recognized*, but the location of the obstruction is frequently surrounded by many difficulties As pain is not always referred to the seat of obstruction, it constitutes an unimportant symptom in localizing the lesion Meteorism begins on the proximal side of the obstruction, consequently when the obstruction is located below the sigmoid flexure it is first observed over the descending colon, when in the transverse colon, over the ascending colon, and when in the small intestines, over the umbilical region Vomiting of intestinal contents will take place early if the obstruction is located high up, if low down it is a late symptom True stercoraceous vomiting indicates that the obstruction is located somewhere in the large intestines Careful palpation of the abdomen and in doubtful cases manual rectal exploration will constitute important aids in determining the location and nature of the obstructing cause Peritonitis is no contraindication to abdominal section, but the operation should be done, if possible, before this complication appears If after a most thorough and careful examination we are unable to ascertain the seat of the obstruction, the abdomen should be opened in the median line for manual exploration A dilated intestine would indicate that the cause of the obstruction is lower down, while a collapsed bowel can only be expected on the peripheral side of the obstruction If the cause of the obstruction is not found by the usual methods of examination, a systematic search should be made by searching for the ilio cæcal region, and exploring the intestine, inch by inch, in both directions When the patient is still in good condition, and the abdomen is sufficiently soft and yielding for making the examination, localization of the obstruction can usually be made without great difficulty When opposite conditions are presented, when the patient is in a condition of collapse, and the abdomen tympanitic and tense, and the seat of the obstruction cannot be readily located, Nélaton's laparo ileotomy should be performed in the right iliac region, as affording the best chance for the relief of the most urgent and dangerous symptoms When gangrene of the bowel is found, typical circular resection should give way to the formation of a fæcal fistula, if the obstruction is situated sufficiently low down so that such a procedure would not interfere with the maintenance of nutrition should the patient recover from the operation Roser has made the observation that after correcting a volvulus of the sigmoid flexure the torsion of the bowel is liable to return To prevent such an accident he advises that the loop of intestine, when placed in proper position, should be stitched to the abdominal wall by passing a few sutures through the mesentery of the bowel and the parietal peritoneum of the left abdominal wall After disinvagination the same precaution is suggested to prevent reinvagination, the sutures in this instance must fix the lower portion of the *intussusceptum* In conclusion it is appropriate to allude to the following concise and practical rules laid down by J Grey Smith for treating intestinal obstruction by abdominal section

1 Make the incision in the middle line below the umbilicus

2 Fix upon the most dilated or the most congested part of the bowel that lies near the surface, and follow it with the finger as a guide to the seat of obstruction

3 If this fail, draw the intestine out of the wound, carefully covering it, until increase of distension or congestion or both in one of the coils gives an indication that the stricture lies near

4 If there be considerable distension of the intestines, evacuate their contents by incision, and suture the wound Never consider an operation for intestinal obstruction inside the abdomen complete until the bowels are relieved from over distension

5 Be expeditious, for such cases suffer seriously from shock The whole operation ought to be concluded in half an hour

V *Enterectomy* —Circular resection of the intestine has been on trial for a number of years and has been performed for different pathological conditions The results obtained thus far have shown that success depends largely upon the condition of the tissues through which the incisions are made It may be stated as a rule that the healing process progresses most favorably when the resected ends have not undergone inflammatory changes by extension of the pathological conditions which have necessitated the operation. Thus Jaffe has collected 121 cases of enterectomy reported since 1876, of this number thirty six were done for gangrene of the bowel, with 70 per cent of deaths or formation of fæcal fistula, while of the remaining cases done for intestinal wounds, artificial anus, stenosis and tumors, only 44 per cent terminated unfavorably. A study of these cases induced him to decide against the advisability of primary enterectomy for gangrene of the intestines. The same opinion is entertained by von Bergmann. The experience of Billroth also corroborates the opinion, which is now generally accepted, that primary typical enterectomy and enterorrhaphy should not be performed in cases of gangrene resulting from strangulated hernia and internal strangulation.

Of six cases of enterectomy for gangrene operated upon by Billroth only one recovered, and in this case a fæcal fistula formed, which, however, closed without further interference in three weeks. In contrast with these cases were five enterectomies combined with extirpation of tumors affecting the bowel primarily or by extension, of this number three recovered. Clinical experience appears to have definitely settled the course to pursue in cases of gangrene of the bowel, viz. to establish a preternatural anus, and, if this fails to close by more conservative means, to resort to circular resection and suturing after the intestine has been restored to its normal condition. That resection of a large portion of the intestinal canal is not always compatible with health is well illustrated by a case reported by Baum in which he removed 137 ctm. of the small intestines in a woman 40 years of age. The patient was suffering from strangulated femoral hernia. Taxis was only partially successful. On opening the sac an offensive fluid escaped, and a portion of the omentum was removed. Peritonitis followed and a swelling formed in the abdomen above the crural ring, which broke and a fæcal fistula was established. Rapid emaciation ensued, symptoms of strangulation made a laparotomy necessary. A mass of intestines was found twisted into a bunch which could not be unravelled, and as it was surrounded by an abscess it was resected and the ends of the intestine were united with sutures. Patient recovered from operation and improved for several weeks. Six months later progressive emaciation resulted in death.

At the autopsy the seat of resection could not be found, showing how completely and perfectly the intestinal wound had healed. The reporter was of the opinion that death was caused by the great shortening of the intestinal tract.

In 1881 Koeberle resected 2.05 m. of the small intestines in a girl 22 years of age on account of multiple stenoses of the bowel. The patient made a favorable recovery. Kocher has quite recently removed by resection 160 ctm. of small intestine for gangrene in a case of strangulated hernia. The patient recovered and at the time the report was made remained in good health.

Notwithstanding the favorable results obtained by Koeberle and Kocher, Baum's case should indicate to us that there must be a limit to the extent with which resection can be practised with immunity, and that in multiple lesions of the intestines with intervening healthy portions of the bowel it would be preferable to make multiple resections rather than to include a too extensive tract of healthy intestine with the injured or diseased portions. Nearly all operators emphasize the importance of not interfering unnecessarily with the vascular supply of the bowel for fear of causing gangrene of the resected ends. Lauenstein is so strongly convinced of the importance of this precaution that he claims the portion of intestine deprived of its mesentery always becomes gangrenous, consequently in such cases he advises resection of that portion of the intestine rather than trust to the doubtful restoration of the vascular supply by collateral circulation. That it is important to interfere as little as possible with the blood-supply of the resected ends of the bowel no one will doubt, but that in the case of the small intestines this fear has been overestimated, I am convinced. During my experiments on the pancreas last year I often detached the mesentery from the duodenum and upper portion of jejunum in dogs and cats to the extent of from two to twelve inches, and yet gangrene of the bowel occurred only in exceptional cases. The vascular supply was restored either by the denuded surface of the bowel coming in contact and forming adhesions, the detached portion of the intestine assuming the shape of a horse shoe, the open portion corresponding to the cicatrix between the denuded surfaces, or the circulation was restored by the growth of new vessels of large size along the detached portion of the bowel, thus restoring to perfection the mesenteric circulation.

The apprehension of causing gangrene by even a slight interruption of the circulation appears to be well founded in resection of the large intestine. Czerny lost two cases of resection of the colon from gangrene produced by this cause. Lauenstein has found three similar cases recorded where, during operations on the stomach, the transverse colon was detached more or less from the meso colon. We should *a priori* expect a greater liability of gangrene to occur from a limited interruption of the circulation in operations upon the large intestines, from the larger size of the tube, the more scanty blood-supply, and more particularly from the greater difficulties encountered with in the formation of the collateral circulation.

Appended to the report of a successful case of resection of the large intestine for malignant disease, Weir gives the statistics of thirty five cases in which excision of a cancerous intestine was resorted to, and in all cases save one (Schede's) the disease had involved the large intestine. Of this number it is to be noted that of the five cases in which the operation was done during the exhaustion attendant upon the acute obstruction of the bowel, all died from the the shock of the operation, hence this condition is considered by Schede to contra indicate the operation. Of these thirty-three cases there was a mortality of seventeen, or 51.5 per cent, only a little greater than that which results from resection of the large intestine from other causes, and which is given by Maydl at 50 per cent. Aside from the shock ten died within forty-eight hours, in a number of cases the progress was complicated by perforative peritonitis and intestinal fistula. When the latter occurred in the course of an otherwise favorably progressing case, it, as a rule, closed later spontaneously. The perforation was due either to faulty suturing or gangrene of the margin of the wound from detachment of the meso colon. In cases in which the disease returned it took place in three cases in less than one year, in four others between one and two years, in one case over two years, and in Gussenbauer-Martini's case the patient was free from the disease four years after the operation.

The propriety of excision of the colon for malignant disease can therefore not be questioned, the more so if it is found on exploration that the diseased tissue cannot be removed an artificial anus can be established at once with or without excision, which will at any rate remove the symptoms due to obstruction. In two of Billroth's cases, in which the cancer affected the descending colon in one instance, and the sigmoid flexure in the other, so much of the bowel was removed that the ends could not be united, an artificial anus was established, but in both instances a fatal termination followed, in one from collapse, and in the other from septic peritonitis.

VI. *Rupture of Diaphragm.*—Rupture of the diaphragm with escape of the abdominal organs into the cavity of the chest, is a rare accident, but when it does occur it is so uniformly fatal when treated on the expectant plan that in these days of heroic surgery it would appear only reasonable to make an effort to save life by abdominal section, or by an opening into the chest. Either procedure would enable the surgeon to replace the dislocated organs and to close the rupture by suturing. A number of traumatic ruptures of the diaphragm, with protrusion of the abdominal organs into the cavity of the chest, have been reported where, during life, at least a probable diagnosis could be made. All of the cases reported by Butlin and Brinton occurred on the left side. The physical signs on which the diagnosis was based consisted of tympanitic resonance over the side of the chest which contained the prolapsed intestines, with diminution of vocal fremitus and respiratory sounds over an area corresponding to the displacement of the lung. In pneumothorax respiration is abdominal, in traumatic diaphragmatic hernia the respiratory movements are costal, and the abdomen is flattened, conditions which are suggestive of the escape of gas containing intestines into the cavity of the chest. Symptoms of intestinal obstruction indicate strangulation of the protruded bowel. Guttmann regards displacement of the heart, in the absence of other causes, the most reliable diagnostic symptom.

An interesting case of traumatic diaphragmatic hernia which came into Albert's Clinic has been described by von Horoch. The patient received a stab wound immediately under the left scapula. He died two days later with symptoms of asphyxia. The post mortem examination showed that the left lung and diaphragm were punctured by the knife. Through the wound in the diaphragm a portion of the stomach, which had also been opened had escaped into the left pleural cavity. The reporter found three similar cases in literature. He suggested that, in a diaphragmatic hernia, new or old, presenting symptoms of strangulation the chest should be opened sufficiently by rib resection to permit reduction, and to close the wound in the diaphragm in such a manner that the sutures should embrace the serous coat of the stomach. That the recognition of a diaphragmatic hernia is not always an easy task, even after opening the abdominal cavity, is illustrated by Ferran's case. This surgeon performed laparotomy on a young woman who had suffered from symptoms of intestinal obstruction for seven days. The small intestines having been turned out from the abdominal cavity, a careful examination of their whole length and of the cæcum, sigmoid flexure, and rectum was made without the discovery of any cause for the obstruction. The wound was closed and the patient rallied well and showed signs of improvement until next morning, when sudden collapse manifested itself, with speedy death. Post mortem examination showed the existence of a diaphragmatic hernia from laceration, almost the entire transverse colon had escaped into the left pleural cavity, the distended loop of the intestine displacing the heart and the left lung. In the space near the diaphragmatic ring it was noticed that the constriction of the bowel was such as to hardly admit the tip of the index finger. Upon trying to reduce the hernia the ascending gut slipped back into the abdominal cavity without offering any resistance.

The establishment of a route to the diaphragm through the chest is not practicable on account of the frequency with which pleuritic adhesions are found and the greater amount of additional traumatism as compared with abdominal section, hence the latter should be preferred for the relief of diaphragmatic hernia in all cases where a probable diagnosis can be made, and where symptoms of strangulation dictate the propriety and justifiability of the operation. If the injury is produced by a penetrating wound of the chest, the method of operation suggested by von Horoch would be applicable, and in case the symptoms pointed also to visceral injury of the abdominal organs it should be combined with abdominal section.

VII. *The Treatment of Peritonitis by Abdominal Section and Drainage.*—The great fatality of acute diffuse peritonitis under the old or expectant method of treatment gives some support to the recently proposed treatment by incision and drainage. This now common and general surgical procedure has been already applied with great success for the relief of inflammatory lesions of all of the other serous cavities. The first record of an operation performed deliberately on account of acute peritonitis was proposed and executed by Dr. Wiltshire in 1868. About thirteen years ago Mr. Lawson Tait followed Wiltshire's example. Since that time he affirms he has never allowed a patient to die of peritonitis without opening the abdomen whenever he was permitted to perform the operation. He has performed abdominal section forty four times on account of the presence of peritonitis and the operation has been completely successful in forty-one cases

As peritonitis is usually only a secondary manifestation of an antecedent primary cause, it appears plain that the treatment by surgical interference will be most successful in cases where the disease has not become diffuse, and where the original cause can be removed Cases of this kind are represented by

1 *Perforative Peritonitis* —In order to recognize this condition early when most amenable to surgical treatment, it is important to allude to some of the most prominent early symptoms Observation of a number of cases of peritonitis following perforation has satisfied Ebstein that the abdominal walls usually remain tense and rigid without distension, the abdomen may be flat and even depressed The contracted condition of the abdominal muscles remains for a variable length of time, when it is followed by distension with or without rigidity The contraction of the muscles diminish as the paralytic symptoms increase Ebstein asserts that the absence of the normal liver dulness cannot be depended upon as a pathognomonic symptom of perforative peritonitis He mentions a case of perforation of the stomach in which no gas had escaped into the peritoneal cavity to produce displacement of the liver The liver also remains in its normal position in cases where fluid escapes into the peritoneal cavity, and where the organ has formed adhesions by previous attacks of perihepatitis The absence of vomiting in a case of peritonitis or its sudden cessation in the beginning of an acute attack indicates, when the patient is conscious, that either perforation of the stomach has followed peritonitis Vomiting is not present when perforation has taken place into the peritoneal cavity or the bursa omentalis

A case reported by Ebstein appears to prove that vomiting again may take place in cases of perforation of the stomach as soon as the opening in the stomach has become closed by adhesions to neighboring organs Perforation of the appendix vermiformis, bursting of a pyo salpinx or pelvic abscess furnish familiar illustrations of perforative peritonitis, where a timely laparotomy would hold out encouraging prospects for a favorable recovery by operative treatment Mr Treves has also shown that nearly all abscesses about the cæcum are in reality intraperitoneal, so that in opening these abscesses the surgeon always has to deal with the peritoneal cavity As these abscesses are generally circumscribed by adhesions, a failure to open them in time may result again in perforation and secondary diffuse peritonitis

Mr Howard Marsh relates a successful case of abdominal section for suppurative peritonitis produced by the bursting of an abscess in the mesentery around old tubercular glands into the peritoneal cavity The patient was a young man 19 years of age, who had suffered some time with symptoms of diffuse peritonitis The abdomen was found exceedingly tender and distended The incision was made over the most prominent portion of the swelling on the outside of the linea semilunaris and gave exit to two or three pints of fœtid pus The distended coils of small intestines could be felt through the wound The cavity was washed out with a weak solution of carbolic acid and drained The patient made a slow but good recovery

J W Taylor reports an interesting case of acute hydronephrosis where rupture of the cyst into the peritoneal cavity produced great collapse, and where a timely laparotomy prevented a fatal peritonitis The patient was a girl 15 years of age, who was attacked suddenly with pain in the left lumbar region, and vomiting, followed by the appearance of a fluctuating tumor in the same side, which was at the time diagnosticated as acute hydrops of the left kidney She suddenly became collapsed, which with other grave symptoms indicated rupture of the cyst and extravasation of its contents into the peritoneal cavity The abdomen was opened at once through the median line The abdominal cavity was thoroughly cleansed and the remaining portions of the cyst contents were removed by puncturing with the trocar The cyst wall was sewed to the abdominal wound, and against all expectations the patient rallied and improved In a few days the cyst refilled, which necessitated a second incision and drainage by means of a glass drain Urine was discharged through the wound, but the patient improved As no calculus could be found by an exploration of the interior of the cyst, it was believed that the left ureter had become completely obliterated, which would necessitate a nephrectomy at some future time

That even perforation of a large pelvic abscess into the peritoneal cavity may terminate in recovery by timely and well applied surgical treatment is well illustrated by a case reported by Mr Treves, in a paper read before the Royal Medico-Chirurgical Society, March 10, 1885 The patient was a female 21 years of age, who had suffered for three months from chronic pelvic peritonitis, following severe gonorrhœa During this time a large purulent collection, containing very offensive matter, had formed near the pelvic brim The acute symptoms were due to the bursting of the abscess and extravasation of its contents into the general peritoneal cavity On the following day the abdomen was opened under antiseptic precautions, the patient at the time being in a very critical condition The peritoneum and intestines showed signs of diffuse recent inflammation The peritoneal cavity contained a quantity of semi-opaque fluid, mixed with flakes of lymph and pus The whole peritoneal cavity was washed out with many quarts of water, and a drain introduced The symptoms improved promptly, and the patient recovered

These cases furnish abundant proof that in cases of perforative peritonitis, irrespective of the nature of the material which has been extravasated, our only resource which affords any encouragement whatever, is abdominal section In cases of this kind it is important to search for the cause of the peritonitis, and to treat the conditions, if necessary, by operative measures, the toilet of the peritoneal cavity can be most effectively accomplished by copiously flushing with warm sterilized water rendered slightly alkaline by the addition of chloride of sodium As in these cases we can never be certain that the peritoneal cavity has been rendered perfectly aseptic, it is always *advisable to resort to drainage.* We have every reason to hope that in the future perforation of the stomach or intestines will be treated by abdominal section, as it holds out the only possibility of preventing death from the consecutive peritonitis by removing the extravasation and preventing further escape by closing the rupture. In such instances it is essential to search for the perforation, which must be treated in the same manner as intestinal wounds, after which the peritoneal cavity is cleansed, drained, and the wound closed.

The successful local treatment of tuberculosis has recently been extended to

2. *Tubercular Peritonitis.*—Koenig has called attention to the difficulty met with in the diagnosis of circumscribed ascites following tuberculosis of the peritoneum, and other fluctuating tumors of the abdominal cavity. He refers particularly to the peculiar kind of fluctuation found in these cases as an almost pathognomonic evidence. The fluctuating waves are large and are conveyed from one wall to the other, and the undulations are imparted to the abdominal wall.

Von Holst reports a case of tuberculosis of the peritoneum which was remarkable from the fact that on palpation over the abdomen dulness and fluctuation were felt as distinctly as in ascites, which on post-mortem was not found to exist. The deception was due to firm adhesions which had formed between the omentum and intestines.

Not infrequently one or more smaller swellings are felt in the vicinity of the large one. Clinically it has been shown that the swelling may decrease in size for a time or that it may remain stationary for a considerable length of time. Tuberculosis of the peritoneum is most frequently found as a complication of tuberculosis of other organs, but sometimes it occurs as a primary lesion in persons without any hereditary taint.

Bucquoy observed a case which had its origin in a cheesy tubercular degeneration of the ovaries. Koenig reports four cases of abdominal section performed for tuberculosis of the peritoneum. The patients were all females. One of them remained well two years after the operation. The exudation was usually found immediately beneath the anterior abdominal wall, the intestines, uterus and ovaries being pushed backward. The cyst wall was always found lined with a thick fibrinous wall which presented all the microscopical appearances characteristic of tuberculosis. After incision the fluid was evacuated, the sac washed out with carbolized water, and the inner surface of the cyst wall dusted with iodoform. In the case which remained well after two years the cavity was drained, and the patient left the hospital with the drainage tube. The fistulous opening healed subsequently. Koenig is of the opinion that in some cases of primary tuberculosis of the peritoneum a radical cure can be effected by laparotomy and local treatment.

3. *Chronic Peritonitis with effusion.*—The most favorable pathological condition of the peritoneum for surgical treatment is chronic inflammation with serous effusion. Abdominal section with drainage relieves the pressure promptly, and thus favors reabsorption and the restoration of the physiological balance between secretion and absorption. Savage reports that he has performed laparotomy in six cases of subacute peritonitis attended by more or less effusion, and all of his patients recovered.

4. *Ascites.*—Dr. A. G. Caille, of New York, has recently called the attention of the Academy of Medicine to the value of permanent drainage in ascites. He related two cases of cirrhosis of the liver with marked ascites, in which he had inserted a drainage tube into the peritoneal cavity at the linea alba, with the result of affording great relief of all the distressing and dangerous symptoms, and probably prolonging life for a considerable period. In one case an autopsy could not be secured, but in the other one was made, when it was found that there was not the slightest indication of peritonitis at the point where the fistula was made. If permanent drainage of the peritoneal cavity is possible without causing inflammation, it is obvious that the treatment of ascites by drastic cathartics, diuretics, and other debilitating measures should be abandoned in favor of this surgical procedure.

(*To be concluded.*)

MEDICAL PROGRESS

A HYPODERMIC SOLUTION OF CAFFEINE.—TANRET (*Repert. de Pharm.*, March, 1886), recommends this formula:

Caffeine	37 grains.
Sodium benzoate	45 "
Distilled water	10 c. c.

Mix the benzoate and the caffeine in a mortar, add the water, and filter.

—*Am. Journ. of Pharm.*, May, 1886.

THE INCOMPATIBILITY OF CALOMEL AND BROMIDE OF POTASSIUM.—VIGIER (*Gaz. Hebdom. de Med. et de Chir.*, May 6, 1886), remarks that calomel is decomposed on the addition of potassium bromide, although more slowly than when the iodide is added. Nobody he thinks, would give the two drugs within five or six hours of each other, but it might happen, for example, in a case of infantile convulsions, that, two practitioners being called in quick succession, the second one might order one of these drugs after the other had been given by the advice of the first one. He gives the caution, therefore, that in such cases their incompatibility should be borne in mind. —*New York Medical Journal*, May 22, 1886.

THE INJECTION OF ANATOMICAL PREPARATIONS.—A. K. BJELOUSSOW recommends (*Archiv f. Anatomie*, November, 1885) for this purpose a mixture of borax and gum arabic. The mass is injected cold, and is then fixed by immersion in spirits. By treating the preparation with glycerine the injection is rendered transparent, and it can be removed at any time by acting upon it with dilute acetic acid.—*The American Journal of the Medical Sciences*, April, 1886.

CORRECT LIST OF THE OFFICERS OF THE PRELIMINARY ORGANIZATION OF THE NINTH INTERNATIONAL MEDICAL CONGRESS

As several of the leading medical journals have recently attempted to give their readers a list of the general officers of the Congress and the Presidents of the Sections without taking the trouble to secure correctness, we think it proper to reproduce the general officers of the Congress, the members of the Executive Committee and of the Local Committee of Arrangements at Washington, and the Presidents of the Sections, as arranged by the Executive Committee at its meeting, on the 3d and 4th inst It will correct the errors published by others, and will be useful for reference by correspondents

FOR GENERAL OFFICERS OF THE CONGRESS

PRESIDENT

N S Davis, M D , LL D , Chicago, Ill

VICE PRESIDENTS

W O Baldwin, M D , Montgomery, Ala
Wm Brodie, M D , Detroit, Mich
W W Dawson, M D , Cincinnati, O
J A Grant, M D , Ottawa, Canada
E M Moore, M D , Rochester, N Y
Tobias G Richardson, M D , New Orleans, La
Lewis A Sayre, M D , New York, N Y
J M Toner, M D , Washington, D C
The President of the American Medical Association
The Surgeon General of the United States Army
The Surgeon General of the United States Navy
The Supervising Surgeon General of the United States Marine Hospital Service

SECRETARY GENERAL

John B Hamilton, M D , Washington, D C

TREASURER

E S F Arnold, M D , New York, N Y

CHAIRMAN OF THE FINANCE COMMITTEE

Richard J Dunglison, M D , Philadelphia, Pa

CHAIRMAN OF THE EXECUTIVE COMMITTEE

Henry H Smith, M D , Philadelphia Pa

CHAIRMAN OF THE LOCAL COMMITTEE OF ARRANGEMENTS

A Y P Garnett, M D , Washington, D C

EXECUTIVE COMMITTEE OF THE CONGRESS

Henry H Smith, M D , Chairman, Philadelphia, Pa
N S Davis, M D , LL D , Chicago, Ill
John B Hamilton, M D , Washington, D C
E S F Arnold, M D , New York, N Y
Richard J Dunglison, M D , Philadelphia, Pa
A Y P Garnett, M D , Washington, D C
F S Dennis, M D , New York, N Y
Abram B Arnold, M D , Baltimore, Md
Wm T Briggs, M D , Nashville, Tenn
DeLaskie Miller, M D , Chicago, Ill
James F Harrison, M D , University Virginia, Va
F H Terrill, M D , San Francisco, Cal
Wm H Pancoast, M D , Philadelphia, Pa
J H Callender, M D , Nashville, Tenn
A B Palmer, M D , LL D , Ann Arbor, Mich
J Lewis Smith, M D , New York, N Y
E Williams, M D , Cincinnati, Ohio
S J Jones, M D , LL D , Chicago, Ill
Wm H Daly, M D , Pittsburgh, Pa
A R Robinson, M D , New York, N Y
Joseph Jones, M D , New Orleans, La
Albert L Gihon, M D , U S N , Washington, D C
John P Gray, M D , LL D , Utica, N Y
Jonathan Taft, M D , Cincinnati, O

LOCAL COMMITTEE OF RECEPTION AND ARRANGEMENT

A Y P Garnett, M D , Washington, D C , Ch'n
The Surgeon General of the U S Army
The Surgeon General of the U S Navy
The Supervising Surgeon General of the U S Marine Hospital Service
J H Baxter, M D , U S Army
J M Toner, M D , Washington, D C
N S Lincoln, M D , Washington, D C
C H A Kleinschmidt, M D , Washington, D C , and forty other members in the District of Columbia

PRESIDENTS OF THE SECTIONS

General Medicine —Abram B Arnold, M D , Professor of Clinical Medicine, Baltimore, Md

General Surgery—William T Briggs, M D, Professor of Surgery, Nashville, Tenn

Military and Naval Medicine and Surgery—Henry H Smith, M D, formerly Professor of Surgery and Surgeon-General of Pennsylvania, Philadelphia, Pa

Obstetrics—DeLaskie Miller, Ph D, M D, Professor of Obstetrics, Chicago, Ill

Gynæcology—James F Harrison, M D, Professor of Medicine, Obstetrics and Medical Jurisprudence, University of Virginia

Therapeutics and Materia Medica—F H Terrill, M D, Professor of Therapeutics, San Francisco, Cal

Anatomy—William H Pancoast, M D, Professor of General, Descriptive, and Surgical Anatomy, Philadelphia, Pa

Physiology—J H Callender, M D, Professor of Physiology, Nashville, Tenn

Pathology—A B Palmer, M D, LL D, Professor of Pathology and Practice of Medicine, Ann Arbor, Michigan

Diseases of Children—J Lewis Smith, M D, Professor of Diseases of Children, New York, N Y

Ophthalmology—E Williams, M D, Professor of Ophthalmology and Otology, Cincinnati, Ohio

Otology—S J Jones, M D, LL D, Professor of Ophthalmology and Otology, Chicago, Ill

Laryngology—William H Daly, M D, Pittsburgh, Pa

Dermatology and Syphilis—A R Robinson, M D, Lecturer on Dermatology and Syphilis, New York, N Y

Public and International Hygiene—Joseph Jones, M D, Professor of Chemistry and Clinical Medicine, New Orleans, La

Collective Investigation, Vital Statistics and Climatology—Albert L Gihon, U S N, Washington, D C

Psychological Medicine and Nervous Diseases—John P Gray, M D, LL D, Professor of Psychological Medicine and Medical Jurisprudence, Utica, N Y

Dental and Oral Surgery—Jonathan Taft, M D, Professor of Dental and Oral Surgery, Cincinnati, O

MILITARY DRILL IN PHYSICAL TRAINING

At the meeting of the Section for Clinical Medicine of the Suffolk District Medical Society on April 14, Dr Charles F Withington read a paper on "Military Drill as a means of Physical Training for Boys" For some years the military drill has been the only physical exercise provided for the boys of the public schools of Boston, and the result seems to have been in every way satisfactory All boys over 13 years of age are required, to drill except when furnished with a physician's certificate of disability With those familiar with the military drill there can be no question as to its value as a physical exercise, and of its good effects, unless too severe, in giving symmetry to the muscular and osseous systems Even the drill without arms has a marked effect upon limb and chest measurement, as shown by Fetzer several years ago Dr Withington's paper only partially covers the ground of the subject, and he concludes, on insufficient data it seems, that the drill is not beneficial, but prejudicial The overwhelming mass of testimony is on the other side Dr Withington goes so far as to claim that the drill will cause asymmetry, but a vast amount of positive evidence must be brought forward before a verdict of "guilty" can be reasonably rendered On the other side, in favor of the drill in school, is the testimony of the Boston Committee, given in the report of 1868, signed by J Baxter Upham, Calvin Page, S A Green, and Ezra Palmer, the report of the same Committee in 1873, signed by Upham, Edson, Shattuck, and Woods, the report of Mr Philbrick in 1874, the report of the Boston Committee in 1875, of the Head-Master of the Roxbury School in 1875, of the Head-Master of the Dorchester School, of General W T Sherman, in writing of the Michigan Military Academy, of General J M Schofield, and of Drs John Moran and Henry P Bowditch, who wrote, in 1880, in the Annual Report of the School Board of Boston "The establishment of Military Drill is one of the few provisions made by the School Board for the physical training of the pupils under its charge, and no one who has observed the soldierly bearing of the members of our school battalion, can have any doubt of its value as a means of securing a full and symmetrical development of the physique"

Of course it would not be a difficult matter to select from a school or army regiment perhaps one person who has some asymmetry But this, so far from showing that the drill caused the asymmetry, only seems to show that the asymmetry was produced in spite of the drill, or that is was probably present to a larger extent before drill exercise was commenced Professor Sargent is of the opinion that lateral curvature is often caused by the drill His opinion is based on the examination of Havard students and members of the Young Men's Christian Union Before receiving this opinion as one of value, however, it is necessary to ask whether those young men were in the habit of playing tenpins, which, of all games, is probably most productive of asymmetry It is doubtless true, also, that in some schools the guns are too heavy for the pupils, an evil which is very easily avoided or remedied

It seems that if the small amount of drill used in schools will cause curvature and asymmetry, the very great amount in use at West Point and Military Schools generally, and in regiments at army posts would bring about such a state of asymmetry that the whole United States Army would be one sided, and present a uniform lateral curvature And if the normal effect of the drill is to cause asymmetry it seems that the care with which cadets are selected is not only useless but absurd But as, on the suggestion of Dr Henry I Bowditch, the discussion on this subject was adjourned for a future meeting of the Section, we may leave the matter for the present, and hope to present the subject more fully in a future issue of THE JOURNAL

NOTICE TO NEW MEMBERS OF THE AMERICAN MEDICAL ASSOCIATION —We have received letters from several who became members of the Association for the first time at the meeting in St Louis, expressing disappointment that they have not begun to receive THE JOURNAL immediately after the adjournment We would remind all such that we cannot know at this office what new members are entitled to THE JOURNAL until the Treasurer has had time to go over the entire registration list and to furnish us with the names and addresses of all new members, which usually requires from one to two weeks As soon as we receive the list from the Treasurer, the names are added to the mail list, and the journals are sent

AMERICAN MEDICAL ASSOCIATION

Thirty-seventh Annual Meeting, held at St Louis, May 4, 5, 6 and 7, 1886

OFFICIAL REPORT

The Association assembled in the Exposition Building at 11 A M, May 4, 1886, and was called to order by DR LEGRAND ATWOOD, Chairman of the Committee of Arrangements The President, Wm Brodie, M D, of Detroit, Vice Presidents, Drs S Logan, La, A Y P Garnett, D C, Chas Alexander, Wis, the Permanent Secretary, Dr Wm B Atkinson, Philadelphia, the Assistant Secretary, Dr Wm C Glasgow, Mo, the Treasurer, Dr R J Dunglison, Philadelphia, and the Librarian, Dr C H A Kleinschmidt, D C, occupied their respective positions

Prayer was offered by Rev M Schuyler, D D, of Missouri

The CHAIRMAN, DR ATWOOD, introduced HON D R FRANCIS, Mayor of St Louis, who welcomed the Association as follows

THE MAYOR'S ADDRESS

"It is highly appropriate that the American Medical Association should hold its annual Convention in the healthiest City upon the American Continent As the official representative of the city, I extend to you a cordial greeting The Municipal Government bids you welcome, and says to you, 'If you seek a healthy city, look around you' Our people have anticipated your coming with pleasure, and, with their characteristic hospitality, have prepared for your entertainment Your brethren of the Association have heralded your advent with pride and exultation, and have made every provision for your pleasure and enjoyment The home of McDowell, Pope, Hodgen, and many other honored members of your profession, welcomes you for your own sake The calling which you have selected is a noble one The science of medicine has been revered from all ages, and its expounders have been highly and worthily esteemed The art of curing disease is co ordinate with the accidents and infirmities to which mankind is liable, and some rude forms of applying the art of healing were practiced by the most barbarous of people The early history of medicine is so mixed up with mythology that it is difficult to distinguish truth from fiction The idea was prevalent in the early ages that disease was a punishment inflicted by a high power, and consequently its treatment was relegated to priests, and was attended with superstitious rites To what extent that idea prevails at the present day, and how far those practices have been handed down from the past, it is difficult to say, but it is none the less true that he who ministers to the physical wants of man is by many held in as high esteem as he who ministers to his spiritual wants The history of medicine is the history of science, religion, society, progress No science is more worthy the attention of mankind, and no nobler study can be engaged in No brighter intellects have adorned history than those which grace the rolls of your profession 'Peace hath her victories not less renowned than war' Many of the discoveries of your predecessors have been in advance of the age in which they lived, and have proved of untold value to the human race Chiron, with his pupil Æsculapius, Hypocrates the father of rational medicine, Praxagoras, the discoverer of the relations between the pulse and the general condition of the system, the great Galen, whose doctrines were implicitly accepted for twelve centuries, and until Esalius, the anatomist, joined issue with them, Harvey, the discoverer of the circulation of the blood, Haller, the physiologist, Jenner, with his discovery of vaccine virus, are a few of the immortal names which have honored your profession, and which you delight to honor For the sake of your profession, its achievements, and its objects do we welcome you, and not alone for that That is reflected light, and although soft, pleasant, and to a high degree illuminating, it can not long keep step with the rapid march of the present day To have done is to hang out of fashion As your brethren have in the past kept pace with the spirit of their times, so in the progressive age of to day is your profession abreast with the vanguard of science The world is almost daily electrified by the discovery of some important principle or its application in some new branch, and in no profession have these occurred more frequently than in yours. In no age of civilization or society have the principles of your science been so generally and so successfully taught, and put into effective practice as in the present. Hygiene is to-day more intelligently observed than ever before, and, thanks to your thoughtfulness and advice, it is being enforced in the construction of our abodes, and practiced in the routine of our daily life. You are continually discovering and disseminating information which preserves health, prevents suffering and prolongs life. For your own sakes, therefore, are you thrice welcome. We recognize among you many whose names are already prominent in the world of science, and we trust that this Convention may result in bringing forward many others. These annual assemblages of the medical profession can not but be productive of much good. Besides promoting acquaintanceship and cultivating friendship, it opens up new fields of research and diverts thought into new channels. The ramifications of medicine are so extensive, and its possibilities are so great that specialties are daily becoming more numerous. Occasions like this are valuable to you, and of course are appreciated and taken advantage of. I cordially welcome you here and trust that your deliberations may be harmonious and satisfactory, beneficent to your association, promotive of science and conducive to the good of the community."

Dr. Atwood on behalf of the profession, delivered an address of

WELCOME FROM THE PROFESSION

Dr. Atwood said, after the excellent speech of the Mayor he felt it difficult to add anything on behalf of the medical men of St. Louis, His Worship having practically covered the whole ground. The local profession had made public in every way the fact that the association intended honoring the city by meeting in it, and the citizens had united with them in a desire to make their guests as comfortable as possible. There was something exceedingly appropriate in the association visiting St. Louis during the presidency of Dr. Brodie, seeing that just thirty-two years ago that doctor was admitted to membership at that city. It It was also highly apropriate because St. Louis had witnessed the life labor of men distinguished in the medical profession, whose reputation had become national, and in some instances cosmopolitan. Here had labored Beaumont, whose profound physiological researches had resulted in so much, and also Joseph Nash McDowell, nephew of the great Ephriam McDowell, whose name was inscribed in the annals of medicine never to be erased, by his illustrious discovery and performance of ovariotomy, a man who had saved the lives of thousands of women by demonstrating the propriety of this operation. Too much was given to the pæan of those who destroyed life, but a man who had made a discovery such as this had done more toward ameliorating the condition of mankind than any General whose glories were sung. J. N. McDowell opened the first medical school west of the Mississippi, and he (Dr. Atwood), although he did not look as old as he was, was present on that occasion. Here also lived and labored John S. Moore, once Vice-President of the Association, and the first to deliver a lecture west of the Mississippi, Charles A. Pope, who during his life was first surgeon and first gentleman of the Mississippi Valley, and others who had conferred unmeasurable benefits on the profession and the public. If the spirits of the illustrious dead are permitted to revisit the scenes loved by them on earth, there were present in their midst the spirits of these and of other illustrous surgeons who had joined them on the other shore. If so, he had no doubt their advice to members of the association would be to preserve the National Code of Ethics as the Palladium of their honor and to regard the open enemy of it as a Pandora with her box open, and the secret enemy as a serpent which, with its deadly wiles, had crept into Paradise. There was nothing left for him to do but to extend ten thousand welcomes to the members of the Association.

Ex-Presidents Drs. N. S. Davis, J. M. Toner, D. W. Yandell, T. G. Richardson, H. F. Campbell, and P. O. Hooper, by invitation, were seated upon the platform.

The programme and other arrangements for the session were read and approved.

It was announced that protests had been entered against the delegates from the Philadelphia County Medical Society, the New York Academy of Medicine, the Tri-State Medical Society, the Mississippi Valley Medical Association, and the Davidson County Medical Society.

DR. D. J. ROBERTS, of Tenn., protested against the Tennessee State Medical Society.

THE CHAIRMAN offered a list of *Members by Invitation*, who were, on motion, elected.

VICE-PRESIDENT DR. S. LOGAN then took the Chair, and THE PRESIDENT, DR. WM. BRODIE, delivered the *Annual Address*. (See p. 505, JOURNAL of May 8.)

On motion of DR. J. H. MURPHY, of Minnesota, the thanks of the Association were tendered the President for his able address, and the special points in it were referred to a committee to be appointed by the Chair.

A memorial from the Women's Christian Temperance Union was offered, and on motion referred to the Section on State Medicine.

DR. J. S. LYNCH, of Baltimore, presented and read the report of the Committee on

PRELIMINARY ORGANIZATION OF THE INTERNATIONAL MEDICAL CONGRESS OF 1887

Your committee on the preliminary organization of the Ninth International Medical Congress, to be held in Washington, D. C., in 1887, have the honor to respectfully report

That your committee, in accordance with your instructions, after mature deliberation, adopted the necessary rules for the organization, nominated general officers for the Congress and its Sections and a local committee of arrangements at Washington, with power to increase its membership, and in accordance with Rule 10, as heretofore published in THE JOURNAL of the Association, they have constituted the proposed officers of the Congress, and the Presidents of its Sections, as an Executive Committee, for the further prosecution of the work of organization, and your committee herewith submit a list of the members of the organization

OFFICERS OF THE CONGRESS

President—Nathan S Davis, of Chicago

Vice-Presidents—Wm O Baldwin, of Alabama, William Brodie, of Michigan, W W Dawson, of Ohio, J A Grant, of Ottawa, Canada, E M Moore, of New York, Tobias G Richardson, of Louisiana, Lewis A Sayre, of New York, J M Toner, of Washington, D C, The President of the American Medical Association, The Surgeon-General U S Army, The Surgeon General U S Navy, The Supervising Surgeon-General U S Marine Hospital Service

Secretary General—John B Hamilton, of Washington, D C

Treasurer—E S F Arnold, of New York

Chairman of the Finance Committee—Richard J Dunglison, of Philadelphia, Pa

PRESIDENTS OF SECTIONS

General Medicine—A B Arnold, of Baltimore, Md

General Surgery—Wm T Briggs, of Nashville, Tenn

Military and Naval Surgery—Henry F Smith, of Philadelphia, Pa.

Obstetrics—De Laskie Miller, of Chicago, Ill

Gynæcology—James F Harrison, of the University of Virginia.

Therapeutics and Materia Medica—F H Terrill, of San Francisco, Cal

Anatomy—Wm H Pancoast, of Philadelphia, Pa

Physiology—J H Callender, of Nashville, Tenn

Pathology—A B Palmer, of the University of Michigan

Diseases of Children—J Lewis Smith, of New York, N Y

Ophthalmology—E Williams, of Cincinnati, Ohio

Otology—S J Jones, of Chicago, Ill

Laryngology—W H Daly, of Pittsburgh, Pa

Dermatology and Syphilis—A R Robinson, of New York City

Public and International Hygiene—Joseph Jones, of New Orleans, La

Collective Investigation, Vital Statistics and Climatology—Albert L Gihon, U S Navy, Washington, D C

Psychological Medicine and Nervous Diseases—John P Gray, of Utica, N Y

Dental and Oral Surgery—Jonathan Taft, of Cincinnati, O

On motion of Dr A L Gihon, U S N, it was *unanimously* accepted and adopted

Dr Henry H Smith, Pa, offered a motion to reconsider this vote

On motion of Dr A L Gihon, this motion was laid on the table

AMENDMENTS TO THE CONSTITUTION

being in order, Dr N S Davis brought up that relating to Officers of Sections

Dr D J Roberts moved to amend it by substituting "first day of the session, at 3 P M"

A motion by Dr E Smith, of Mich, to lay it on the table, was lost

A motion by Dr W Bishop, of Pa, to postpone it until after the report of the Committee on the President's Address, was declared out of order, the point of order being raised by Dr I N Quimby, of N J, that it was not germane to the subject

A number of other amendments to the amendment were proposed and discussed by Drs E Smith, Dudley S Reynolds, F Staples, J H Murphy, J B Murdoch, W Allport, and others, when the amendment was adopted as follows, by a large majority

Amendment—"Strike out the whole of the third paragraph of Section 2 of the By-laws, and substitute the following On the second day of each annual meeting each Section shall nominate its own officers to serve for the next ensuing year, their duties to commence with the close of the annual meeting at which they are nominated and to continue until their successors are appointed"

A division being called for, a vote was again had, and the President decided that it had been adopted

The various delegates were requested to select their representatives for the Committee on Nominations, and to report to the Permanent Secretary in the morning On motion the Association adjourned until Wednesday at 10 A M

WEDNESDAY, MAY 5—SECOND DAY

THE PRESIDENT, DR WM BRODIE, called the Association to order at 10 A M He announced as the

SPECIAL COMMITTEE ON THE PRESIDENT'S ADDRESS,

Drs J H Murphy, of Minn, A L Gihon, U S N, and Alonzo Garcelon, of Maine

The Chairman of the Committee of Arrangements offered the names of some members by invitation, who were on motion elected

The Permanent Secretary then read the names of the

NOMINATING COMMITTEE

Ark, P O Hooper, Col, J W Graham, Conn, W C Wile, D of C, J W Bulkley, Fla, T O Summers, Ga, J W Bailey, Ill, J E Owens, Ind, T B Harvey, Iowa, W Watson, Kan, C V Mottram, Ky, W H Wathen, La., Jos Jones, Me, Chas E Webster, Mass, E W Cushing, Md, G H Rohe, Minn, H H Kimball, Mich, H O Walker, Miss, P W Rowland, Mo, J F Dudley, Neb, W M Knapp, N J, E L B Godfrey, N Y, E S F Arnold, N Ca, C J O'Hagan, Ohio, H J Sharp, Pa, J C Lange, R I, H R Storer, S Ca, R A Kinloch, Tenn, Duncan Eve, Texas, J F Y Paine, Ver, A T Woodward, Va, G B McCorkle, W Va, G W Baird, Wis, W T Galloway, U S A, Ely McClellan, U S N, J C Speir, U S M Hosp, •W Wyman, Dakota Ter, J B Van-Velsor, New Mexico, W R Tipton

It was announced that they would meet at 11 A M

Dr Nicholas Senn, Chairman of the Section on Anatomy and Surgery, then delivered the *Address in Surgery* (See p 589)

A protest was made by a delegate from Tennessee against Dr Eve serving on the Nominating Committee from Tennessee, as the Society from which he came had been protested against

Dr S C Gordon, of Portland, Me, Chairman of the Section on Obstetrics and Diseases of Women, then delivered the *Address in Obstetrics* (See p 561, Journal of May 22)

Vice-President A Y P Garnett then took the Chair, and Dr A L Gihon, Chairman of the

RUSH MONUMENT COMMITTEE,

read the report

Your Committee begs to report that in obedience to your resolutions on the 30th of April, 1885, at the thirty-sixth annual meeting of the Association at New Orleans, La, the Rush Monument Committee has been instituted by the appointment of one member from each of the States, Territories and National services represented in the Association, and the Standing Committee thus organized will forthwith proceed upon the duty intrusted to it by the Association, to wit the collection of funds, etc, for the erection of a statue to Dr Benjamin Rush, in the City of Washington, by the members of the profession of medicine in the United States

Your Committee, appointed at Washington, in 1884, by the lamented Dr Austin Flint, in its report presented at New Orleans, enumerated the monuments which have already been erected at the National Capital in commemoration of the men who have contributed to the National renown, and stated that appropriations had also been made by Congress for statues to Lafayette and Garfield Since that report, and doubtless in consequence of it, various public bodies have proposed similar memorials to their great leaders The Church, already represented in the person of Martin Luther, is to have its statue to Wesley The deaf mutes have taken action toward the erection of a monument on their beautiful Kendal Green to their eminent teacher, Gallaudet Philanthropy is to have its marbly effigy of Peabody, and the intrepid explorers, who have lifted the curtains of dense jungle and rugged mountains upon new lands, are to be personated in him who, greatest of them all, led the way to this New World, while Grant and McClellan, Hancock and Shields, McDonough and Barry, are to be added to the already long array of Presidents and military and naval heroes

With statesmen, rulers, soldiers and sailors, the scientist and the philanthropist, the discoverer and the teacher, the jurist and the divine, all given prominence among the adornments of this beautiful Capital City, no further time should be lost by the medical profession in completing its enduring testimonial of one who was not only a great physician and teacher of medicine, philosopher, philanthropist, and accomplished writer, but a fearless patriot and founder of the Republic, a signer of the Declaration of Independence, an officer of the army of the Revolution, and one of the authors of that Federal Constitution under which we now happily live

With this announcement, the Rush Monument Committee will at once undertake the work of obtaining subscriptions, which have been limited by resolution of the Association to one dollar from each member of the profession of medicine in the United States, and receiving such voluntary donations as may be made by persons interested in this great undertaking

All of which is respectfully submitted

For the Committee
Albert L Gihon, M D, Ch'n
George H Rohe, M D, Sec'y
J M Toner, M D, Treasurer

I am directed by the Rush Monument Committee to report to the Association the election of Dr Geo H Rohé, of Maryland, to be Secretary, and of Dr Joseph M Toner, of the District of Columbia, to be Treasurer

In accordance with the instituting resolution the following members, resident in and near Washington, constitute, with the Chairman, an Executive Committee

Albert L Gihon, U S N, Chairman, George H Rohe, Baltimore, Md, Joseph M Toner, Washington, D C, Henry H Smith, Philadelphia, Pa, Chas Smart, U S A, Washington, Preston H Bailhache, U S M H Service, Baltimore, Samuel J Jones, Chicago, Ill

I am also directed to report that the Committee has adopted rules for the collection and responsible expenditure of the funds collected for the purpose of the monument, and has determined upon Riggs' Bank, at Washington, as the depository of said funds

Respectfully submitted

Albert L Gihon, Chairman

On motion, the report was accepted

Dr I N Quimby called up the amendment to the amendment to the By laws creating a

SECTION ON MEDICAL JURISPRUDENCE,

and offered a motion that it be adopted

After some debate it was adopted

The Committee of Arrangements presented a number of invitations, which were read and accepted

A communication from the Texas State Medical Association was received and ordered on file

Dr W Bishop, of Pa, moved that the President be requested to announce, with the title of a paper and the name of its author, the time allowed for its reading Rejected

An invitation to meet the American Climatological Association next week in Philadelphia was read

On motion of Dr N S Davis the Association adjourned until Thursday morning

---

Thursday, May 6 —Third Day

The President called the Association to order at 10 A M, prayer being offered by Rev R G Brank, D D

The Committee of Arrangements reported invitations to visit places of interest

The Committee on Nominations then nominated the following

OFFICERS FOR 1887

President—Dr E H Gregory, St Louis, Mo

1st Vice President—Dr E H Miller, of Stillwater, Minn

2d Vice President—Dr W B Welch, of Boonesboro, Ark

3d Vice President—Dr William H Pancoast, of Philadelphia

4th Vice President—Dr William C Wile, of New London, Conn

Permanent Secretary—Dr William B Atkinson, of Philadelphia

Assistant Secretary—Dr J Nevins Hyde, of Chicago, Ill

Treasurer—Dr R J Dunglison, of Philadelphia

Librarian—Dr C H A Kleinschmidt, of Washington, D C

Committee on Necrology—Dr J M Toner, of District of Columbia, Chairman, Ala, Jerome Cochran, Ark, C Watkins, Cal, Beverley Cole, Col, T H Hawkins, Conn, Frank H Whittemore, D Columbia, C H A Kleinschmidt, Del, Lewis P Bush, Fla, R B Burrows, Ga, R Battey, Ill, L H Montgomery, Ind, J F Hibberd, Iowa, J Williamson, Kan, C V Mottram, Ky, R M Farleigh, La, J W Duprè, Me, A J Fuller, Mass, M G Parker, Md, T B Evans, Mich, S S H French, Miss, B F Kittrell, Mo, L Bremer, Minn, W W Mayo, Neb, E M Whitten, N H, J J Berry, N J, I N Quimby, N Y, John Shrady, N C, Eugene Grissom, Ohio, J F Baldwin, Pa, D G Brinton, R I, C W Parsons, S C, R A Kinloch, Tenn, J Y Crawford, Tex, J W McLaughlin, Ver, E F Upham, Va, George B McCorkle, W Va, J H Pipes, Wis, S S Riddell, U S Navy, J C Speir, U S Army, M K Taylor, U S Mar Hosp Service, H S Austin, Dak Ter, J B Van Velsor, N M, G W Hansom

Committee on State Medicine—Ala, G A Kitchen, Ark, J A Dibrell, Jr, Cal, F H Terrill, Col, P R Thomas, Conn, Geo B Porter, D Columbia, J D Patterson, Fla, E T Sabal, Ga, J A McGaston, Ill, J H Hollister, Ind, J H Beasley, Iowa, P W Lewellyn, Kan, S Schenck, Ky, Wm Bailey, La, C W Day, Mass, M C Ledwood, Ira Russell, Md, John Morris, Mich, H B Baker, Miss, M S Grafft, Mo, J M Allen, Minn, W A Stenchfield, Neb, A R Mitchell, N H, G P Conn, N J, E I B Godfrey, N Y, E S F Arnold, N C, C J O Hagan, Ohio, H J Sharp, Pa, W Sniveley, R I, W T Parker, S C, C Kolbrock, Tenn, J B Nowling, Tex, C H Wilkinson, Ver, H D Holton, Va, J E Chancellor, W Va, S D Wilson, Wis, C Alexander, U S N, A L Gihon, U S A, E McClellan, U S M H Service, W H Long, Dak, J B Van Velsor, N M, W R Tipton

Members of Judicial Council—N S Davis, Ill, H Brown, Ky, William Brodie, Mich, D J Roberts, Tenn, R C Moore, Neb, T A Foster, Me, James A Gray, Ga

Trustees of THE JOURNAL—P O Hooper, Ark, A Garcelon, Me, L S McMurtry, Ky

Place of next meeting, Chicago, Ill, the first Tuesday in June, 1887, Chairman of the Committee of Arrangements, Charles Gilman Smith, M D, of Chicago, Ill

On motion the report was unanimously adopted

OFFICERS OF SECTIONS

Surgery and Anatomy—Chairman, H H Mudd, St Louis, Secretary, John B Roberts, Philadelphia

Practice of Medicine—Chairman, J S Lynch, Md, Secretary, J B Marvin, Ky

Obstetrics and Diseases of Women—Chairman, F M Johnson, Mo, Secretary, W W Jaggard, Ill

Ophthalmology, Otology, and Laryngology—Chairman, X C Scott, Ohio, Secretary, J H Thompson, Mo

Diseases of Children—Chairman, DeLaskie Miller, Ill, Secretary, W B Lawrence, Ark

Oral and Dental Surgery—Chairman, J S Marshall, Ill, Secretary, E S Talbot, Ill

State Medicine—Chairman, G H Rohé, Md, Secretary, Walter Wyman, U S M H S

Vice-President Logan took the Chair, and Dr A L Gihon read the following

REPORT ON THE PRESIDENT S ADDRESS

Your Committee to whom was referred those portions of the address of the President of the Association embodying suggestions of action on your part beg to report

1 That in their opinion it is proper and desirable that this Association shall without delay memorialize Congress in behalf of the pending resolution to appoint a scientific commission of three members of the profession of medicine to visit the habitats of yellow fever in Cuba, Mexico and Brazil, with a view to determine the validity of the claims of Drs Carmona and Freire to have discovered a means of preventing or modifying attacks of that disease

2 That your committee are not agreed among themselves as to the suggested recession from the recommendation of the use of the metric system in medicine

3 That they heartily approve of the suggestion of the President that the Association having created a Section on Medical Jurisprudence, shall further establish a Section on Dermatology and Syphilis

4 That they concur with the President as to the wisdom of the provision that the several Sections shall elect their own officers from among the men of recognized authority and experience in the special work of such Sections, and they are further of the opinion that the efficiency of these Sections will be enhanced by the continuance in office from year to year of the Secretaries of said Sections

5 That they endorse the views of the President respecting THE JOURNAL OF THE ASSOCIATION, and the exclusive proprietary interest of this Association in the papers and reports which are made part of its transactions

6 That the Association should emphatically denounce the endorsement by certificate, advertisement, testimonial or indirect approval in any form, of proprietary remedies and appliances, and should instruct the Judicial Council to take action in all such cases without formal presentation of charges, that, in the words of the President "The stigma of professional disgrace shall rest upon any regularly educated physician who allows his name to be advertised as the endorser of any patent, secret or proprietary medicine

7 That it is desirable that the Association shall appoint a Committee at this meeting to consider the advisability of amending the organic law of the Association by the establishment of Branches or in whatever other way may be deemed best, and to report thereon at the next annual meeting of the Association

8 That they earnestly re echo the wish of the President that the members of the profession will cordially cooperate in the effort to make the American session of the International Congress creditable to the country and attractive and instructive to the foreign visitors, sacrificing their personal and private piques and disappointments in generous emulation to contribute to that success, which had been unconditionally pledged in the invitation tendered the foreign members of the Congress to meet in the United States

All which is respectfully submitted

John H Murphy, Minnesota,
Albert L Gihon, U S Navy,
Alonzo Garcelon, Maine,
Committee

Dr Gihon moved its adoption

Dr J F Hibberd, Ind, objected to its adoption, and Dr J B Murdoch moved that it be read in sections

Dr W T Bishop, Penn, moved that it be postponed, and made the first special order under new business

After some further discussion Dr E Smith called the previous question, which was sustained The question, "Shall the main question now be put," was adopted by a large majority, and the vote being taken the report was adopted as a whole

The President then resumed the Chair

Dr Edward Jackson, of Philadelphia, called for the report of the Judicial Council on the Philadelphia County Medical Society The President announced that it was now in the hands of the Council

Dr N S Davis, Chairman, then read the Report of the Standing Committee on Meteorological Conditions and their Relations to the Prevalence of Diseases, also Concerning the Subject of Collective Investigation of Disease in Cooperation with the Committee of the British Medical Association

In behalf of the Standing Committee on Meteorological Conditions and their Relations to the Prevalence of Diseases, the undersigned would respectfully report progress The Signal Service of the General Government has kindly continued to furnish the reports from the several stations originally selected, and as far as practicable all the other elements of the investigation have been continued Sufficient materials have been accumulated for a valuable and interesting report, but on account of the apparent tendency of epidemic cholera to extend westward over Europe and perhaps reach this country, it has been thought desirable to continue the observations and records undertaken until the apparent cholera season has passed by A full report may be expected at the next annual meeting of the Association

In relation to Collective Investigations of Disease in connection with the Committee of the British Association, it is proper to state that your Committee acting in harmony with both the Committee of the British Association and the Committee of the Eighth International Medical Congress appointed at Copenhagen, have had a large number of convenient blanks with necessary instructions, asking for observations and records concerning the more important diseases, selected jointly by the Committee of the British Association and that of the International Congress, distributed to members of the profession in this country, asking them to fill the blanks as far as possible and return the same to the Chairman or Secretary of the Committee on or before January, 1887, for the purpose of enabling the Committee to tabulate and analyze the results for both the next meeting of this Association and for the Ninth International Congress at Washington, September, 1887 The foregoing statement of progress is respectfully submitted

By N S Davis,
Chairman of Committee

On motion the report was adopted

Dr James M Keller, of Arkansas, Chairman of the Committee, read the

REPORT ON CREMATION

It will be remembered, Mr President, that at the meeting held at St Paul four years ago, I first brought the subject of cremation before the Association in the shape of a resolution, asking its reference to the Committee on State Medicine Each year since it has been called up and purposely referred back without discussion, until at New Orleans it was referred to a special Committee to report to day, and your Committee respectfully submit this paper Since the subject was first mentioned it has become one upon which much thought and deliberation have been given, not only in this, but in other countries, and much has been written in advocacy of it, not only by the medical profession, but by people in all the walks of life Secular and religious journals, as well as medical, have all discussed it Indeed, so much has been written about it, and all in its favor, that your Committee deem it unnecessary to do more than offer one or two reasons why fire should be substituted for earth burial—why immediate and complete destruction of disease germs should supplant their dangerous planting and propagation We believe that the horrid practice of earth burial does more to propagate the germs of disease and death, and to spread desolation and pestilence over the human race, than does all man's ingenuity and ignorance in every other custom or habit

Not satisfied with doing all the evil we can in life, custom up to the present time makes us do a thousand fold more after death

From the moment the heart ceases to beat and vitality leaves the body of man or brute, decomposition, inexorable in its laws and hideous and horrible to contemplate, begins—in every phase of its decay, slow, repugnant and dangerous even to beasts of the field, and in no way does earth burial check or impede, but on the contrary, under certain atmospheric and climatic conditions rapidly aid and nourish the death dealing germ It only hides from sight the danger that sooner or later we take into our stomachs with each draught of spring or well water, or into our lungs with each inspiration Mr Darwin, in a paper written on the formation of mold, proved that in many places the whole superficial layer of earth has passed through the intestines of worms In some cases more than three inches of it had been deposited in fifteen years, and in another the depth in eighty years had reached thirteen inches

Strongly confirmatory of these conclusions are the investigations of Pasteur on the Etiology of Chorbon, in which he shows that this earth mold, brought up by worms over the graves of its dead, abounded with the same specific germ which propagated the disease, and these same organisms filled the intestines of the worms Who dares deny the assertion that the earth burial of any body, dead of a zymotic disease, is simply the planting of the seeds of such disease, sooner or later to grow and reproduce itself and other pestilential troubles among survivors? Dr Friere in his investigations of the cause of yellow fever in Rio de Janeiro found the soil of cemeteries in which its victims had been interred, absolutely filled with microbism organisms, identical with those found in the vomit and blood of his patients who had died with it Mother earth a foot below the surface, indeed from the surface to the body, swarmed with the characteristic germ Hence his justification in characterizing those cemeteries as the nurseries of the disease

The fatal delusion that the earth renders harmless and innocuous the corpse must be dispelled Incontrovertible proof of the fact that the vicinity of graveyards is unhealthy is superabundant That the dead do kill the living is equally true, and that cholera, yellow fever and the whole list of zymotic and infectious diseases are propagated by contaminating the earth and air and water supplies, is as true as that sewer gas or sewage water do propagate disease Point to a city if you can, whose growth has demanded the removal of the dead from its cemetery, that will not attest the truth of the rapid production of disease and death in all neighboring localities God's half-acre must become a thing of the past The graveyard must be adandoned The time has come for us to face squarely the problem, how to dispose of our dead with safety to the living And your Committee has an abiding faith that you will earnestly and at once say, that the "earth was made for the living, not for the dead," and that "pure air, pure water and pure soil" are absolutely necessary for perfect health Only skeptics deny that the dead do poison these three essentials of human life

Embalming and mummifying are equally as unsafe, and surely far more disgusting than earth burial, and equally as repulsive was the ancient German custom of "fire burial" Modern cremation alone is stripped of all objectionable features At an early day only a few minutes of time will be necessary to give back to loving survivors all that is worth preserving—a few pounds of harmless pure, clean, white ashes A process (the only safe one) the quickest, simplest and cheapest, leaving no vestige that is repugnant, offensive or injurious—strictly in conformity to nature's laws—accomplishing in a few moments what putrefaction after burial never does

In conclusion your Committee begs to amend the original resolution so that it may read

Resolved, That cremation or incineration of the dead has become a sanitary necessity in all populous cities, and that this Association advise its adoption as far as practicable

J M Keller,
S Logan

A motion having been made to adopt the report, Dr A Y P Garnett moved to lay it on the table, which was negatived

Dr I N Quimby called for the previous question, which was sustained, and having been agreed to the report was adopted by a majority of 159 to 106

Dr T A Reamy, of Ohio, moved a reconsideration in order that the report, which was in some sense objectionable, might be more fully discussed The motion for reconsideration was carried by 198 to 70

On motion of Dr John Morris, of Md, the report with its conclusions was referred to the Section on State Medicine

Dr J B Roberts, of Penn, offered a motion that the Permanent Secretary be instructed to give official information why the report of the Judicial Council was not given on Wednesday The motion was declared out of order

Dr Roberts then appealed from this decision, and the vote being taken the Chair was sustained by a vote of 191 to 25

Dr James T Whittaker, Chairman of the Section on Practical Medicine Materia Medica, and Physiology, then delivered the *Address in Medicine* (See Journal of May 15, p 533)

On motion of Dr J M Toner it was resolved that the Association be requested to return to the Judicial Council the report in the case of the Philadelphia County Medical Society, for the purpose of hearing additional testimony, and all interested were invited to appear before the Judicial Council then in session

Dr John H Rauch, of Illinois, Chairman of the Section, then delivered the *Address in State Medicine*, which was referred for publication

ENTERTAIMENT OF THE INTERNATIONAL CONGRESS IN 1887

On motion of Dr A Y P Garnett, seconded by Dr D W Yandell, it was

Resolved, That the delegates to this Association be requested upon their return to their homes to adopt such means as may to them seem best to call the attention of their respective delegates to the Congress of the United States to the desirability of making an appropriation to assist the medical profession of this country in properly receiving and entertaining the International Medical Congress in Washington in 1887 such cases without formal presentation of charges, that, in the words of the President "The stigma of professional disgrace shall rest upon any regularly educated physician who allows his name to be advertised as the endorser of any patent, secret or proprietary medicine

7 That it is desirable that the Association shall appoint a Committee at this meeting to consider the advisability of amending the organic law of the Association by the establishment of Branches or in whatever other way may be deemed best, and to report thereon at the next annual meeting of the Association

8 That they earnestly re echo the wish of the President that the members of the profession will cordially cooperate in the effort to make the American session of the International Congress creditable to the country and attractive and instructive to the foreign visitors, sacrificing their personal and private piques and disappointments in generous emulation to contribute to that success, which had been unconditionally pledged in the invitation tendered the foreign members of the Congress to meet in the United States

All which is respectfully submitted

John H Murphy, Minnesota
Albert L Gihon, U S Navy,
Alonzo Garcelon, Maine,
Committee

Dr Gihon moved its adoption

Dr J F Hibberd, Ind, objected to its adoption, and Dr J B Murdoch moved that it be read in sections

Dr W T Bishop, Penn, moved that it be postponed, and made the first special order under new business

After some further discussion Dr E Smith called the previous question, which was sustained The question, "Shall the main question now be put," was adopted by a large majority, and the vote being taken the report was adopted as a whole

The President then resumed the Chair

Dr Edward Jackson, of Philadelphia, called for the report of the Judicial Council on the Philadelphia County Medical Society The President announced that it was now in the hands of the Council

Dr N S Davis, Chairman, then read the Report of the Standing Committee on Meteorological Conditions and their Relations to the Prevalence of Diseases, also Concerning the Subject of Collective Investigation of Disease in Cooperation with the Committee of the British Medical Association

In behalf of the Standing Committee on Meteorological Conditions and their Relations to the Prevalence of Diseases, the undersigned would respectfully report progress The Signal Service of the General Government has kindly continued to furnish the reports from the several stations originally selected, and as far as practicable all the other elements of the investigation have been continued Sufficient materials have been accumulated for a valuable and interesting report, but on account of the apparent tendency of epidemic cholera to extend westward over Europe and perhaps reach this country, it has been thought desirable to continue the observations and records undertaken until the apparent cholera season has passed by A full report may be expected at the next annual meeting of the Association

In relation to Collective Investigations of Disease in connection with the Committee of the British Association, it is proper to state that your Committee acting in harmony with both the Committee of the British Association and the Committee of the Eighth International Medical Congress appointed at Copenhagen, have had a large number of convenient blanks with necessary instructions, asking for observations and records concerning the more important diseases, selected jointly by the Committee of the British Association and that of the International Congress, distributed to members of the profession in this country, asking them to fill the blanks as far as possible and return the same to the Chairman or Secretary of the Committee on or before January, 1887, for the purpose of enabling the Committee to tabulate and analyze the results for both the next meeting of this Association and for the Ninth International Congress at Washington, September, 1887 The foregoing statement of progress is respectfully submitted

By N S Davis,
Chairman of Committee

On motion the report was adopted

Dr James M Keller, of Arkansas, Chairman of the Committee, read the

REPORT ON CREMATION

It will be remembered, Mr President, that at the meeting held at St Paul four years ago, I first brought the subject of cremation before the Association in the shape of a resolution, asking its reference to the Committee on State Medicine Each year since it has been called up and purposely referred back without discussion, until at New Orleans it was referred to a special Committee to report to day, and your Committee respectfully submit this paper Since the subject was first mentioned it has become one upon which much thought and deliberation have been given, not only in this, but in other countries, and much has been written in advocacy of it, not only by the medical profession, but by people in all the walks of life Secular and religious journals, as well as medical, have all discussed it Indeed, so much has been written about it, and all in its favor, that your Committee deem it unnecessary to do more than offer one or two reasons why fire should be substituted for earth burial—why immediate and complete destruction of disease germs should supplant their dangerous planting and propagation We believe that the horrid practice of earth burial does more to propagate the germs of disease and death, and to spread desolation and pestilence over the human race, than does all man's ingenuity and ignorance in every other custom or habit

Not satisfied with doing all the evil we can in life, custom up to the present time makes us do a thousand fold more after death

From the moment the heart ceases to beat and vitality leaves the body of man or brute, decomposition, inexorable in its laws and hideous and horrible to contemplate, begins—in every phase of its decay, slow, repugnant and dangerous even to beasts of the field, and in no way does earth burial check or impede, but on the contrary, under certain atmospheric and climatic conditions rapidly aid and nourish the death dealing germ It only hides from sight the danger that sooner or later we take into our stomachs with each draught of spring or well water, or into our lungs with each inspiration Mr Darwin, in a paper written on the formation of mold, proved that in many places the whole superficial layer of earth has passed through the intestines of worms In some cases more than three inches of it had been deposited in fifteen years, and in another the depth in eighty years had reached thirteen inches

Strongly confirmatory of these conclusions are the investigations of Pasteur on the Etiology of Chorbon, in which he shows that this earth mold, brought up by worms over the graves of its dead, abounded with the same specific germ which propagated the disease, and these same organisms filled the intestines of the worms Who dares deny the assertion that the earth burial of any body, dead of a zymotic disease, is simply the planting of the seeds of such disease, sooner or later to grow and reproduce itself and other pestilential troubles among survivors? Dr Friere in his investigations of the cause of yellow fever in Rio de Janeiro found the soil of cemeteries in which its victims had been interred, absolutely filled with microbism organisms, identical with those found in the vomit and blood of his patients who had died with it Mother earth a foot below the surface, indeed from the surface to the body, swarmed with the characteristic germ Hence his justification in characterizing those cemeteries as the nurseries of the disease

The fatal delusion that the earth renders harmless and innocuous the corpse must be dispelled Incontrovertible proof of the fact that the vicinity of graveyards is unhealthy is superabundant That the dead do kill the living is equally true, and that cholera, yellow fever and the whole list of zymotic and infectious diseases are propagated by contaminating the earth and air and water supplies, is as true as that sewer gas or sewage water do propagate disease Point to a city if you can, whose growth has demanded the removal of the dead from its cemetery, that will not attest the truth of the rapid production of disease and death in all neighboring localities God's half-acre must become a thing of the past The graveyard must be adandoned The time has come for us to face squarely the problem, how to dispose of our dead with safety to the living And your Committee has an abiding faith that you will earnestly and at once say, that the "earth was made for the living, not for the dead," and that "pure air, pure water and pure soil" are absolutely necessary for perfect health Only skeptics deny that the dead do poison these three essentials of human life

Embalming and mummifying are equally as unsafe, and surely far more disgusting than earth burial, and equally as repulsive was the ancient German custom of "fire burial" Modern cremation alone is stripped of all objectionable features At an early day only a few minutes of time will be necessary to give back to loving survivors all that is worth preserving—a few pounds of harmless pure, clean, white ashes A process (the only safe one) the quickest, simplest and cheapest, leaving no vestige that is repugnant, offensive or injurious—strictly in conformity to nature's laws—accomplishing in a few moments what putrefaction after burial never does

In conclusion your Committee begs to amend the original resolution so that it may read

Resolved, That cremation or incineration of the dead has become a sanitary necessity in all populous cities, and that this Association advise its adoption as far as practicable

J M KELLER,
S LOGAN

A motion having been made to adopt the report, Dr A Y P Garnett moved to lay it on the table, which was negatived

Dr I N Quimby called for the previous question, which was sustained, and having been agreed to the report was adopted by a majority of 159 to 106

Dr T A Reamy, of Ohio, moved a reconsideration in order that the report, which was in some sense objectionable, might be more fully discussed The motion for reconsideration was carried by 198 to 70

On motion of Dr John Morris, of Md , the report with its conclusions was referred to the Section on State Medicine

Dr J B Roberts, of Penn , offered a motion that the Permanent Secretary be instructed to give official information why the report of the Judicial Council was not given on Wednesday The motion was declared out of order

Dr Roberts then appealed from this decision, and the vote being taken the Chair was sustained by a vote of 191 to 25

Dr James T Whittaker, Chairman of the Section on Practical Medicine, Materia Medica, and Physiology, then delivered the *Address in Medicine* (See JOURNAL of May 15, p 533)

On motion of Dr J M Toner it was resolved that the Association be requested to return to the Judicial Council the report in the case of the Philadelphia County Medical Society, for the purpose of hearing additional testimony, and all interested were invited to appear before the Judicial Council then in session

Dr John H Rauch, of Illinois, Chairman of the Section, then delivered the *Address in State Medicine*, which was referred for publication

ENTERTAIMENT OF THE INTERNATIONAL CONGRESS IN 1887

On motion of Dr A Y P Garnett, seconded by Dr D W Yandell, it was

Resolved, That the delegates to this Association be requested upon their return to their homes to adopt such means as may to them seem best to call the attention of their respective delegates to the Congress of the United States to the desirability of making an appropriation to assist the medical profession of this country in properly receiving and entertaining the International Medical Congress in Washington in 1887

Dr R J Dunglison then read the

(Copy) May 7, 1886

This certifies that we have examined the accounts of receipts and expenditures of R J Dunglison, Treasurer of the Association and find the same correct.

Alonzo Garcelon } Auditing
L S McMurtry } Committee

Dr C H A Kleinschmidt read the

LIBRARIAN'S REPORT,

which was adopted, including its recommendation of an appropriation of $10 for the *Index Medicus*

By request the report of the Committee on Publication was made the first special order of business for Friday

Dr A L Gihon offered an amendment to the By-laws to create a Section on Dermatology and Venereal Diseases This must lay over until 1887

On motion of Dr Gihon it was

Resolved, That a committee of nine members, including the President elect and the four Vice-Presidents elect, shall be appointed by the Chair to consider the various propositions looking to the amendment of the organic law of the Association by the establishment of Branches, or in any other way, said Committee to report at the next annual meeting what measures of reorganization, if any, may be desirable

On motion the Association adjourned until Friday at 10 A M

Friday, May 7—Fourth Day

The President called the Association to order at 10 A M , and prayer was offered by Rev W V Tudor, D D

General W T Sherman having entered the room was invited to a seat on the platform, in accepting which he made a few appropriate remarks

The President announced the following as the

COMMITTEE ON BRANCHES

The President-elect, the four Vice-Presidents elect, Drs N S Davis, J M Toner, and A L Gihon

The Permanent Secretary read the following on behalf of J McF Gaston, of Atlanta, Georgia

Whereas, Authentic reports have been published, indicating that inoculation with the attenuated virus of yellow fever has afforded protection from this disease in more than 6,000 persons, residing in the same localities with others not inoculated who died during an epidemic of yellow fever in Rio de Janeiro, Brazil, and

Whereas, Other evidence of the efficacy of yellow fever inoculation is corroborated by the statements of Dr Horace M Lane, a member of this Association now present, to the effect that he was inoculated by Dr Domingos Freire in Rio de Janeiro and remained in that city without contracting the disease, while many others who were not thus inoculated were attacked and died , and further, that he had the opportunity of verifying the protective influence of inoculation against yellow fever in numerous other cases under his observation, and

Whereas, The facts in regard to the results of this prophylactic against yellow fever warrant the conviction that it is trustworthy and safe in practice, therefore

Resolved, That the American Medical Association recommends prompt action by the United States Government for the investigation of the claims of inoculation against yellow fever, and the appropriation of the means requisite for the expenses of the same, with the appointment of a medical and scientific commission to undertake this inquiry

Resolved, That a committee of three be appointed by the President to memorialize Congress in accordance with this recommendation at the earliest day practicable

The President announced the following as the Committee Drs J McF Gaston, of Atlanta, Ga , P O Hooper, of Little Rock, Ark , and T G Richardson, of New Orleans, La

THE SECTION ON MEDICAL JURISPRUDENCE,

as organized under the amendment adopted at this session, announced that they had chosen the following officers President, I N Quimby, of New Jersey, Secretary, H H Kimball, of Minnesota

Dr Chas K Mills, of Philadelphia, moved that the order of business be suspended to allow the Judicial Council to report, and for other business On motion of Dr J B Hamilton this was laid on the table

Dr J M Toner, Chairman, then read the

REPORT OF THE TRUSTEES OF THE JOURNAL

The Board of Trustees for the publication of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION respectfully submit the following as their Annual Report for the year ending March 31, 1886

For reasons fully stated in the last report the financial year is made to include the receipts and expenditures of THE JOURNAL for the fourth quarter of the second year and the first three quarters of the *third* year of its publication

At the earnest solicitation of the Trustees, Prof Davis consented to continue his labors as editor in-chief during the last year, and under his general supervision THE JOURNAL has been issued regularly and without a single exception either at or before the date of its publication has been mailed to members At the last annual meeting the Trustees instructed the Business Committee to commence the publication of THE JOURNAL upon the account of the Association when the then existing contracts should expire Accordingly for the last nine months THE JOURNAL has been so published The details of this work were committed to the editor, and are so fully set forth in his annual report to the Trustees that we desire to incorporate it in our report to the Association It is as follows

The undersigned respectfully submits the following statements in regard to the progress of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION and its present status, financially and otherwise

Weekly Circulation —At the date of my last annual report, March 31st, 1885, the total regular weekly circulation of THE JOURNAL was 4,020, of which 3,050 were members of the Association as reported to this office by the Treasurer, 850 were subscribers, and 120 to exchanges and advertisers

At this date, March 31st, 1886, the total weekly circulation is 4,271, of which 3,374 are members of the Association as returned by the Treasurer, 645 subscribers, and 252 to foreign and domestic exchanges and advertisers The net increase in the membership during the year has been 324, the net decrease in subscribers 205, and the increase of exchanges, chiefly foreign, and foreign correspondents, 132, thereby giving a net increase in the regular weekly mail list of 251 during the year The number of JOURNALS printed each week during the year has been 4500, being 300 in excess of the previous year, and 229 in excess of the regular mail list Part of these have been required for use as sample copies and extras to contributors, leaving on hand about 75 copies of complete files The decrease in the number of subscribers is occasioned almost entirely by deaths and the change to members by application Regarding it preferable to increase the permanent membership rather than the list of simple subscribers, we have uniformly encouraged the change

Receipts —The receipts at the office of publication relate only to receipts from subscriptions, advertisements, reprints, and extra JOURNALS, all membership dues being sent directly to the Treasurer, and will be accounted for in his annual report From the sources indicated there has been received at this office during the year ending March 31st, 1886, the sum of $5,330 46, of which $2,738 29 were from subscribers, $2,165 07 from advertisers, and $427 10 from those ordering reprints and extras, all of which has been paid to the Treasurer

Assets —During the three past years there has accumulated unpaid subscriptions amounting, at the date of this report, to the sum of $5,435 00 One-half of this will be paid with reasonable certainty by the end of the present JOURNAL year The remaining half, however, is due from parties who became subscribers by signing and returning the original pledges that were sent out before the commencement of the publication, and who, in answer to the many bills sent, have made many fair promises and yet paid nothing thus far I had intended to erase all the names of those who had paid nothing at the commencement of this year But during the last quarter a number have remitted $15 for the whole three years, and it encouraged me to let the list remain to the end of the present volume, in hopes that many more of them might succeed in fulfilling their promises in the same manner None of the receipts for advertisements during the third quarter of the present JOURNAL year, ending March 31st amounting to about $700, is included in this report, for though all good, it is not all paid until after the close of the quarter

Expenses —The total cost of publishing THE JOURNAL, 4,500 copies weekly, during the year ending March 31st, 1886, not including editorial salary and expenses, is $11,410 77, of which $2,906 76 was for the fourth quarter of the second year of publication, leaving $8,504 01 for the first three quarters of the third year of publication But it should be stated that in this amount, for the three quarters of the current year, is included the paper and press-work of reprints, amounting to $427 10, which was returned to the treasury in full by those for whom the reprints were made Deducting the sum received for the reprints, it makes the cost of publication of THE JOURNAL for the first three quarters of the current year, $8,076 91, and a total for the year ending March 31st, 1886, $10,983 67, which is $1,136 51 less than the cost of publication the preceding year, and yet the weekly issue this year is 300 more than last year The saving, however, belongs entirely to the last three quarters of the year, and is owing to two causes First, the reduction of postage on second class mail matter has reduced the aggregate of postage during the last nine months about $300, or at the rate of $400 per annum Second, the change from the publication by contract, to the publication in our own printing office, which was commenced last June, effected a saving of $836 51 since the first of July, 1885, or at the rate of $1,115 34 for the year ending June 30th, 1886 If we make the proper allowance for the 300 additional copies weekly printed this year, it increases the amount of actual saving for the year to $1,500

The total amount drawn from the treasury for the payment of editorial work, which includes foreign and domestic correspondence, reports of medical society proceedings, clinical lectures, etc , and for assistant editorial work proper, during the year ending March 31st, 1886, is $3,115 10, making the total expenses for The Journal for the year ending March 31st, 1886, $14,098 77, and the total receipts, as shown by the report of the Treasurer, $18,567 39

At the last annual meeting of the Board of Trustess I was authorized, on the expiration of the then existing contracts for printing The Journal, to purchase the necessary amount of type and fixtures and establish a printing office owned and conducted exclusively in the interest of The Journal, and superintended by a competent foreman Accordingly, in June, 1885, I purchased of the Illinois Type Foundry Co type and fixtures for direct use in printing The Journal to the amount of $668 87, and paid for carpenter work and labor in fitting up the office and placing the printing material in position, $101 15 In August it became necessary to reprint the whole mail list for directing wrappers, and I purchased of Marder, Luse & Co , Chicago, plain, cheap type, so that the whole mail list, when set up, could be kept permanently on the galleys and permit all changes and additions to be made with the same facility as in correcting proof This cost $274 86, and will serve the purpose for several years at little cost The aggregate amount thus expended to fully equip the printing office for good work was $1,044 88, which is not included in the foregoing figures in regard to the cost of publication of The Journal during the past year, because these materials constitute permanent property, and with trifling additions from time to time will serve their purpose for several years

An accurate inventory of the value of the property now on hand in good order is as follows

Printing material in use for The Journal	$722 42
Printing material in use for the mail list	253 52
Office fixtures and gas fitting	108 00
Total	$1,083 94

I hold an insurance policy on this property for $800 00

In an earlier part of this report it has been shown that by the establishment of The Journal's own printing office, the publication expenses of The Journal during the year ending March 3 st, 1886, have been $1,136 51 less than under the contract system of the previous year, being a saving of $52 57 more than the entire cost of the printing materials now on hand and in good order for future use

During the last nine months that The Journal office has been in operation and under the care of Mr J Harrison White, our foreman, every number issued has been committed to the United States mail on or before the date of its publication, and in much better order than formerly

About $350 more has been expended for editorial labor the year just closed than during the preceding, owing to the employment of more writers, both in the office and in more regular and extensive foreign and domestic correspondence

The only department of The Journal work which has disappointed us during the past year has been in the receipts from advertising We committed this department to the management of a general agent who was familiar with medical advertising, and who agreed to pay The Journal a uniform price for each page that he could fill, and make all his own collections He was confident that he could much increase our revenue from that source But such has not been the result, and a better arrangement must be effected for the future

Some may be disappointed at the moderate increase in the aggregate of members and subscribers receiving The Journal the past year But if it is remembered that since The Journal was established less than three years since, The Journal and the Association have encountered first the defection of the New York New Code party, followed during the last year by the extensive opposition on account of the controversy about the International Medical Congress, it will rather be a matter of surprise that we have had any increase whatever But the figures show that the aggregate increase of members and subscribers has considerably exceeded the discontinuances, and with the disappearance of these temporary subjects of controversy the increase will be much greater annually

Respectfully submitted N S Davis,
Editor of Journal of American Medical Association

In reviewing this report and the enterprise it is of interest to note that contrary to what might have been expected, owing to differences among our professional brethren, the circulation of The Journal has not fallen off, but has increased so that the list has increased 251 The weekly issue of The Journal during last year was 4,200 During the present year it is 4,500 The cost of publication, not including Editor's salary, for the former year was $ 2,120 18, for the present year it is $11,410 77, showing a net decrease of expenses of $709 41 To this should be added amounts received during the present year from the sale of reprints, etc , which give a *net* saving to the Association, by its publication of The Journal of $1136 51, although 300 more copies were published The entire cost of the *plant* for publishing The Journal and all expenses on its account to this date have been $1,044 88, so that in the savings of the last nine months, the entire outlay has been paid, leaving a balance of $91 63 as compared with last year With regard to editoral salary, your Trustees are authorized to expend a sum annually not exceeding $6,000 But they have been unanimous in the opinion that no debts should be incurred on account of the publication of The Journal, which its receipts would not warrant Much to their regret, they have been compelled to limit the amount paid for all editorial work, including foreign and domestic correspondence to the sum of $3,115 10 for the past year

We are not unmindful of what The Journal *should be*, or of what it *will be*, whenever its receipts will warrant such outlay as is made in the development of medical journals published in the interest of private parties The Trustees are confident that the success of the experiment of publishing THE JOURNAL on the account of the Association fully warrants the continuance of the same general policy, and while they will summon to his *aid* all the editoral help which the finances of the Association will warrant, they have solicited Dr Davis to continue his present relations with THE JOURNAL, and we are happy to state that he has consented to remain its Editor

Dr A Garcelon announced that the accounts had been audited and found correct

DR J M Toner then read the

REPORT OF THE JUDICIAL COUNCIL

ST LOUIS, MAY 6, 1886

In the case of Protest against the admission of delegates from Tri State Medical Societies, the Council would state that our constitution recognizes only State Societies, and County, District and local Societies which are affiliated with the State Society Delegates from Tri State Societies are therefore not entitled to admission

In the case of Protest against the registration of delegates from the Davidson County Medical Society, of Tennessee, after careful examination of printed, written and oral testimony and thorough consideration of the same, the Council decide that sufficient evidence has not been presented to warrant denying registration to said delegates, but it also hereby admonishes the Davidson County Medical Society, as soon as practicable, to place itself in more explicit affiliation with the Tennessee State Medical Society

The Protest against the registration of delegates from the Mississippi Valley Medical Association is accompanied by no charges or specifications, and therefore the Council, in accordance with its rules, can take no action upon it

A protest against admission to membership of Dr W Dixon, of Henderson, Ky , is also presented without any evidence accompanying it, and its treatment must be the same

In the case of Protest against the registration of delegates from the Philadelphia County Medical Society, which upon petition was reopened to admit new testimony, after a long and careful re examination, including evidence not before presented, the Judicial Council decide that, notwithstanding the fact that said delegates hold documents usually entitling to registration, it also appears, in evidence, that the methods employed at their election were of such an irregular character as to compel their rejection as delegates by the Council

The Council would also suggest the return of any dues which may have been paid to the Treasurer by said delegates

The Council also refers the Protest and all the papers accompanying it to the Philadelphia County Medical Society for adjudication

J K BARTLETT,
Secretary of Judicial Council

Dr Edward Jackson, of Philadelphia, as a question of privilege, asked the President to rule as to the present status of the Philadelphia County Medical Society The President decided this to be out of order

A communication from the California State Medical Society was received and ordered on file

Dr Eugene Smith, of Michigan, Chairman of the Section, then delivered the *Address on Ophthalmology, Otology and Laryngology* Referred

Dr W D Haggard, of Tenn , Chairman, delivered in brief the *Address on Diseases of Children* Referred

Dr John S Marshall, of Chicago, Chairman, read by title the *Address on Oral and Dental Surgery* Referred

The Committee on Necrology reported that as usual most of the necrological notices had been published in THE JOURNAL, as others would be

The Section on State Medicine sent in the following resolutions

The memorial of the West End Woman's National Christian Temperance Union having been referred to the Section for consideration, the following resolution offered by Dr John Morris, of Baltimore, Md , was adopted and directed to be reported to the Association

Resolved, That we reaffirm the utterances of the American Medical Association concerning the use and abuse of alcohol and its effects upon the body, and recommend the study of hygiene in all our public schools To facilitate this study we urge the speedy passage by the House of Representatives of the Senate Bill now before it, requiring instruction in the effects of stimulants and narcotics in schools under Federal control

The report of the Chairman of the Committee on Cremation, Dr James M Keller, of Arkansas, having been referred by the Association to the Section for consideration, the following resolution offered by Dr G S Franklin, of Ohio, was adopted and directed to be reported to the Association

Resolved, That a committee of this Section be appointed to further consider the subject of cremation, with instructions to report their conclusions to the Section at the next annual meeting of the Association

The address of Dr John H Rauch, of Illinois, Chairman of the Section, before the Association in general session Thursday, May 6, having been referred to the Section for consideration, the following resolution offered by Dr Albert L Gihon, U S Navy, was adopted and directed to be reported to the Association

Resolved, That in accordance with the suggestions of the Chairman in his address before the Association, the American Medical Association direct the Section on State Medicine to prepare and report at the next annual meeting, a form of law regulating the conditions requisite as preliminary to the study of Medicine, the requirements for graduation, and for the license to practice medicine, to be urged upon the several States in order to secure uniformity in methods and results throughout the United States

These resolutions were adopted

The President announced as the

SPECIAL COMMITTEE ON CREMATION

Drs J M Keller, Ark , John Morris, Md , F Formento, La , Samuel Logan, La , and G S Franklin

On motion it was

Resolved, That hereafter the Committee of Arrangements be requested to place the report of the Publication Committee in the order of the first day's proceedings

Dr John B Roberts having offered a series of questions, on motion of Dr A Octerlony, of Ky , they were laid upon the table with but one dissenting voice A motion by Dr J B Hamilton to reconsider was also voted down

The Permanent Secretary read the following list of

DELEGATES TO FOREIGN SOCIETIES

To medical organizations of Europe, Drs N S Davis, Ill , W W Dawson, Ohio, Donald McLean, Eugene Smith, and Wm Brodie, of Mich , B A Watson, of N J , W T Briggs, Tenn , W H Pancoast, James C Wilson and John V Shoemaker, of Penn , L H Montgomery and J L Gray, Ill , E H M Sell and E Cutter, N Y , S C Gordon, Me , and G C Catlett, Mo

Ontario Medical Association, H O Walker, Mich

Canadian Medical Association, Wm Brodie, Mich

Dr John B Roberts then offered his resignation as Secretary of the Section on Surgery, accepted

On motion of Dr W B Atkinson the Chairman of the Section was authorized to fill the vacancy

On motion of Dr A E Baldwin, Ill , that as the resolution introduced by Dr Roberts are a reflection upon our excellent President and Secretary all reference to them be expunged from the minutes

Dr Edward Jackson, Penn , having offered a protest, it was objected by Dr Brinton, Penn , that he was not a regularly accredited delegate, and the protest was unanimously laid upon the table

Dr N S Davis offered a resolution of cordial thanks to the Chairman of the Committee of Arangements, the local officers, and the people of St Louis from whom the Association had received such kind treatment By the suggestion of Dr Octerlony the vote was taken standing, and was unanimous

On motion of Dr A Garcelon seconded by Dr I B Todd, Ky , it was

Resolved, That the thanks of the Association is hereby tendered the medical profession and citizens of St Louis for the cordial and generous reception we, as members, have received at their hands, and we take this occasion to assure them that we take our departure with regret, bearing with us the highest estimation of the generosity and liberality of its citizens, the beauty and healthfulness of its location, at the junction of the two longest and largest navigable rivers of our continent, in the centre of one of the most extensive and fertile agricultural regions of the world, rendering it one of the great commercial and manufacturing centres of the nation, as well as a seat of education, refinement, and the fine arts

Resolved, That our especial thanks are extended to the ladies of St Louis for the elegant social entertainments we have enjoyed at their hands, and as *an acknowledgement we can only say*, God bless the ladies of St Louis

Dr J M Keller offered an

AMENDMENT TO THE BY-LAWS,

making the officers of the Sections again nominative by the Committee on Nominations To lay over until 1887

Drs N S Davis, Ill , and J B Johnson, Mo , having been appointed for the purpose, conducted the President elect, Dr E S Gregory, of St Louis, to the Chair He was introduced by the President, and in taking his place returned thanks to the Association for the honor conferred upon him

The President then bade the members farewell in a felicitous manner, and declared the Association adjourned W B Atkinson, M D ,

Permanent Secretary

Bad Effects of Cocaine in Glaucoma—Societe Française d'Ophthalmologie—Henri Legrand du Saulle

Like most good things in this world, cocaine, which has been so enthusiastically adopted in ocular therapeutics, has proved to have had its reverses, as pointed out by Dr Javal, at a recent meeting of the Academy of Medicine It is known in ophthalmic practice that the instillation of atropine into an eye affected with glaucoma, or even predisposed to that affection, produces a most disastrous effect, and often brings on paroxysms of violent pain in the eye Although this fact is known, yet atropine continues to be applied in glaucomatous affections, but it is presumed only in cases where there has been an error in diagnosis According to Dr Javal, cocaine produces the same deplorable results, for in many cases that came under his own observation the condition of glaucomatous eyes had become aggravated by the use of this agent, and that in certain cases in which the symptoms of glaucoma were scarcely perceptible, cocaine rendered them more marked These symptoms, however, may be successfully combated by the employment of eserine Dr Javal prefers the latter in the form of gelatine discs to that of solution, as being more convenient These remarks offer a very great interest in ophthalmic practice, and also as regards the pathogenesis of a malady concerning the nature of which there is still such a diversity of opinions Divers theories have been proposed to explain the action of cocaine, and while certain authors, as Pfluger, attribute the anæsthetic effect to direct action of the drug on the terminal fibres of the fifth pair of nerves, others, like Eversbusch, think that the contraction of the smaller arteries and the capillary anemia which results are probably the essential cause of the loss of sensibility

The practical fact on which attention should be directed, is that the nutritive activity of the parts af fected is for some time diminished, and that when this nutrition is already weakened, as in persons old and debilitated, the free use of cocaine exposes the patient to certain risks as regards the vitality of his tissues. Hence, it would be imprudent to permit old and enfeebled persons to employ solutions of cocaine except under the direct control of a medical man.

I have taken these remarks from *La France Medicale*, which were published in that journal by Dr. Chevallereau, a rising ophthalmologist, who also gave one or two examples that came under his own observation, of the danger attending the indiscriminate use of cocaine. Among others I may cite the case of a young man aged 20 years, who had been treated for syphilis contracted at Senegal. The patient had a very severe attack of exudative iritis accompanied with increased intra ocular tension, and the most intense pain, which induced the doctor to practise paracentesis of the cornea. A two per cent solution of cocaine had been instilled into the eye four times at intervals of five minutes before the operation. After the paracentesis, a compressive bandage was applied which was removed only the next morning. The patient went on well, he passed a good night, but during the last fortnight the pains were so intense that they prevented sleep. The wound in the cornea healed, but there was in its immediate vicinity a slight cloudy infiltration of the cornea. The doctor prescribed the renewal of the instillations of atropine, but the nurse who was attending the patient dropped into the eye by mistake a solution of cocaine, which she repeated five times during the day. The next morning the cornea became opalescent for about two thirds of its extent. Fortunately the error was discovered in time, when the atropine was resorted to, and in two days after all was right again.

The "Société Francaise d' Ophthalmologie" held its annual meeting at Paris from the 27th to the 29th of April, under the Presidency of Professor Gunning, of Amsterdam, when many interesting papers were read before the Congress. The first subject brought to notice was that of Dr. Dianoux, of Nantes, on "The Treatment of Sympathetic Ophthalmia," and submitted for consideration three methods of treatment in a surgical point of view, viz. Exenteration, enucleation, enervation. Of the three methods Dr. Dianoux gives the preference to enervation, on the following grounds. In the first place, it is less dangerous than the other two operations. In an esthetic point of view, it is interesting to know that after enervation the eye does not become atrophied, and that in consequence it preserves the satisfactory appearance of a normal organ. Moreover, it should not be forgotten that enucleation is often rejected by patients with horror, who on the contrary readily accept an operation like enervation. This operation consists in dividing all the nerves which go to the globe of the eye, the optic nerve being included.

Enucleation, Dr. Dianoux states, does not act in any other way than as a preservative against sympathetic ophthalmia, and it is by the division of all the nerves of the eye that this operation is efficacious. If, then, the effect of the two operations is identical, enervation should certainly be preferred, because in producing the same effect the organ of vision is preserved in its place, which is of course of inestimable value, even though the function be destroyed. As for exenteration, he rejects it in toto on the grounds that the ciliary nerves might become painful and serve as conductors to sympathetic phenomena, and the lymphatic sheaths would remain open to all sorts of infection. From the debate that followed some prefer enucleation (Abadie and Galezowski), others exenteration (de Wecker). Galezowski stated that of 600 enucleations, he had only two cases which proved fatal, one of which was caused by hæmorrhage, which it was impossible to stop.

I have just received a notice to attend the funeral of Dr. Henri LeGrand du Saulle, who died on the 5th inst. at the early age of 56 years, from cerebral congestion. He was a very distinguished member of the profession, and besides being physician to the Salpetriére Asylum, he held many official appointments appertaining to his specialty as an alienist, in which capacity he was one of the leaders. (FROM OUR OWN CORRESPONDENT.)

Extra uterine Fœtation — The Etiology of Potts' Disease—Foreign Bodies in the Œsophagus—Alumni Association of the Woman's Hospital—New York Academy of Medicine.

At the last meeting of the New York County Medical Association, held May 17, Professor Wm. T. Lusk made a very impressive address on the subject of *Extra uterine Fœtation*, his remarks being based on a case which presented many points of unusual interest. The patient was a lady of Wisconsin who ceased to menstruate in September, 1883, and about a month afterward had several attacks of acute paroxysmal pain, one of which was of intense severity. After that pregnancy apparently progressed in a perfectly normal manner until the middle of June, when the fœtal movements stopped. A month later, believing herself to be in labor, she sent for her physician, who found that the uterus was empty, and that a tumor had developed outside of it.

Although the possibility of the existence of abdominal pregnancy was discussed, the diagnosis of this condition was not made by any of a number of physicians who saw her until she came to this city in February, 1885, and consulted Dr. Fordyce Barker. Drs. Thomas and Lusk also saw the case in consultation, and they concurring in the opinion of Dr. Barker, the patient was advised to return to New York in the following June or September, for the purpose of having laparotomy performed. This advice was not followed, however, and after her return she suffered from what was supposed to be remittent fever, but which Dr. Lusk had no doubt, from the conditions found at the autopsy, was in reality septicæmia from putrid absorption.

In the following autumn her health appreciably

The President announced as the

SPECIAL COMMITTEE ON CREMATION

Drs J M Keller, Ark , John Morris, Md , F Formento, La , Samuel Logan, La , and G S Franklin

On motion it was

Resolved, That hereafter the Committee of Arrangements be requested to place the report of the Publication Committee in the order of the first day's proceedings

Dr John B Roberts having offered a series of questions, on motion of Dr A Octerlony, of Ky , they were laid upon the table with but one dissenting voice A motion by Dr J B Hamilton to reconsider was also voted down

The Permanent Secretary read the following list of

DELEGATES TO FOREIGN SOCIETIES

To medical organizations of Europe, Drs N S Davis, Ill , W W Dawson, Ohio, Donald McLean, Eugene Smith, and Wm Brodie, of Mich , B A Watson, of N J , W T Briggs, Tenn , W H Pancoast, James C Wilson and John V Shoemaker, of Penn , L H Montgomery and J L Gray, Ill , E H M Sell and E Cutter, N Y , S C Gordon, Me , and G C Catlett, Mo

Ontario Medical Association, H O Walker, Mich

Canadian Medical Association, Wm Brodie, Mich

Dr John B Roberts then offered his resignation as Secretary of the Section on Surgery, accepted

On motion of Dr W B Atkinson the Chairman of the Section was authorized to fill the vacancy

On motion of Dr A E Baldwin, Ill , that as the resolution introduced by Dr Roberts are a reflection upon our excellent President and Secretary all reference to them be expunged from the minutes

Dr Edward Jackson, Penn , having offered a protest, it was objected by Dr Brinton, Penn , that he was not a regularly accredited delegate, and the protest was unanimously laid upon the table

Dr N S Davis offered a resolution of cordial thanks to the Chairman of the Committee of Arangements, the local officers, and the people of St Louis from whom the Association had received such kind treatment By the suggestion of Dr Octerlony the vote was taken standing, and was unanimous

On motion of Dr A Garcelon seconded by Dr I B Todd, Ky , it was

Resolved, That the thanks of the Association is hereby tendered the medical profession and citizens of St Louis for the cordial and generous reception we, as members, have received at their hands, and we take this occasion to assure them that we take our departure with regret, bearing with us the highest estimation of the generosity and liberality of its citizens, the beauty and healthfulness of its location, at the junction of the two longest and largest navigable rivers of our continent, in the centre of one of the most extensive and fertile agricultural regions of the world, rendering it one of the great commercial and manufacturing centres of the nation, as well as a seat of education, refinement, and the fine arts

Resolved, That our especial thanks are extended to the ladies of St Louis for the elegant social entertainments we have enjoyed at their hands, and as an acknowledgement we can only say, God bless the ladies of St Louis

Dr J M Keller offered an

DOMESTIC CORRESPONDENCE.

LETTER FROM NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Extra-uterine Fœtation—The Etiology of Potts' Disease—Foreign Bodies in the Œsophagus—Alumni Association of the Woman's Hospital—New York Academy of Medicine.

At the last meeting of the New York County Medical Association, held May 17, Professor Wm. T. Lusk made a very impressive address on the subject of *Extra-uterine Fœtation*, his remarks being based on a case which presented many points of unusual interest. The patient was a lady of Wisconsin who ceased to menstruate in September, 1883, and about a month afterward had several attacks of acute paroxysmal pain, one of which was of intense severity. After that pregnancy apparently progressed in a perfectly normal manner until the middle of June, when the fœtal movements stopped. A month later, believing herself to be in labor, she sent for her physician, who found that the uterus was empty, and that a tumor had developed outside of it.

Although the possibility of the existence of abdominal pregnancy was discussed, the diagnosis of this condition was not made by any of a number of physicians who saw her until she came to this city in February, 1885, and consulted Dr. Fordyce Barker. Drs. Thomas and Lusk also saw the case in consultation, and they concurring in the opinion of Dr. Barker, the patient was advised to return to New York in the following June or September, for the purpose of having laparotomy performed. This advice was not followed, however, and after her return she suffered from what was supposed to be remittent fever, but which Dr. Lusk had no doubt, from the conditions found at the autopsy, was in reality septicæmia from putrid absorption.

In the following autumn her health appreciably failed The pulse became very full and rapid, and she had a good deal of diarrhœa, as well as nervous disturbance In December she was advised to go South and live out of doors as much as possible, but by the time she arrived at Atlanta she was unable to leave her room, and remained thus confined for three months She grew worse all the time, but in the early spring succeeded in reaching New York alive Dr Lusk was called to attend her, and was at once struck with the marked change which had taken place in her condition She had a pinched appearance, and was extremely anæmic The pulse was quick, and there was a rise of temperature every evening There was also constant diarrhœa, or else diarrhœa alternating with constipation Very shortly a menstrual period came on, and this was attended with the most marked constitutional disturbance The temperature ranged from 103° to 104°, the pulse was extremely feeble, and there was enormous distension of the abdomen The husband, however, assured Dr Lusk that there was no occasion for being alarmed, as the same disturbances had been noticed at previous menstrual periods, and had been successfully rallied from It was agreed, therefore, that she should be removed to St Elizabeth's Hospital, and that one week before the expected time of the next menstrual period an operation should be performed, this time being decided on in order to allow her to recuperate as far as possible from the exhaustion incident to the serious febrile condition mentioned

Unfortunately, however, the husband's predictions were not verified, and from this time she declined steadily in health and strength Drs Thomas and Barker were called in consultation, and agreed with Dr Lusk that, on account of the exhausted condition of the patient, an operation offered no hope of recovery—the chances in its favor being about one in a thousand The idea of operating was, therefore, abandoned, but later the husband, having learned from Dr Lusk that it was impossible that his wife, in her present condition, could survive another menstrual period, insisted that the operation should be undertaken, as offering the only possible chance (however remote) of recovery

Accordingly, on the 19th of March, much against his will, he performed laparotomy The incision was made in the median line, below the umbilicus, and it was noticed that the severed tissues were entirely bloodless The abdominal walls being then cut through, the tumor was observed, with portions of the fœtus shining through It was found to be entirely free from adhesions to the abdominal walls, and on this account the question arose whether it would not be advisable to remove the tumor entire Fortunately, as the sequel proved, this was not attempted, and when an incision was made into the sac, a quantity of exceedingly fetid gas escaped There was no fluid present, with the exception of about half an ounce of pus The tumor was stitched to the abdominal walls, and the greatest possible care taken to prevent the escape of any portion of the contents of the sac into the cavity of the abdomen The back of the fœtus was turned uppermost and in the process of extraction both the parietal bones dropped off The cutaneous and muscular tissues were almost entirely destroyed, and all the internal organs were found to be shrivelled up Hypodermic injections of whisky were constantly kept up, and the patient was alive at the conclusion of the operation, which lasted about half an hour, as it was performed with the most careful attention to every detail that would tend to bring about a successful result The patient was placed in bed, and rallied fairly well The sac was kept perfectly clean, and the temperature was normal now for the first time For the first twenty four hours there seemed a slight hope that she might recover, but after that time she grew rapidly worse, and died thirty-six hours after the operation

At the autopsy it was found that the uterus, which was in the rear of the tumor, was about the size of an ordinary virgin uterus The Fallopian tube of the left side extended over to the sac, and its fibres were lost in the walls of the latter, showing that the case was, no doubt, originally one of tubal pregnancy, the tube bursting at the time of the attacks of paroxysmal pain There was not the slightest sign of peritonitis, but the sac was so strongly adherent to the intestines that it took Dr Biggs, who made the autopsy, about half an hour to separate the adhesions It was therefore evident that it would have been practically impossible to remove the tumor entire from the abdominal cavity

This case, Dr Lusk remarked, was chiefly interesting from the fact that the patient fell a victim to what he believed to be wholly erroneous teaching All the authorities say that these tumors should not be removed until the health begins to decline The danger was, that if the evidences of septicæmia were not distinctly recognized, operative interference was apt to be delayed until it was too late The reason often given for delaying to operate was, that in the course of time the fœtus would probably be converted into a lithopœdion, but statistics showed that the number of cases in which this occurs is relatively very small The presence of the fœtal tumor in the abdomen was always a source of constant pain and distress As a matter of humanity, therefore, the child ought to be removed soon after it has ceased to live, instead of being allowed to remain until the appearance of symptoms indicating that the constitution of the mother is already undermined The cases which Dr Lusk had investigated showed that nearly all the patients recover when the operation is undertaken at an early period In itself it was not a dangerous procedure, and the bad results which had been noted in so many instances were due simply to the fact that operative measures were adopted only as a last resort The development of the symptoms denoting putrid absorption was almost always insidious, and there were very few cases in which marked symptoms were presented until quite late in the history The effect of the vicious process going on in the system was primarily in the blood, and afterwards resulted in the degeneration of all the parenchymatous organs

Dr Lewis Hall Sayre read a paper entitled *A Contribution to the Etiology of Potts' Disease*, in which he stated that he was among those who look upon traumatism as the exciting and necessary cause, which in a constitution already vitiated need be much less severe to produce spinal or other lesions than in a person of vigorous health A considerable portion of the paper was devoted to the class of cases in which the disease commences on the sides of the bodies of the vertebræ, at the point of their articulation with the ribs, and not in their anterior portion, as is commonly the case They were usually caused by some violence applied to the rib, which originated an inflammatory process at its articulating facet on the spinal column These cases were more than ordinarily obscure in the beginning, and were difficult of diagnosis, as pressure on the head and crowding the vertebræ together seldom caused pain, and the child could run, and even sometimes jump, without pain, and could often bend the body without inconvenience In conclusion, he related a case of this kind of great interest, and his father, Prof Lewis A Sayre, also made some remarks in regard to it

Dr J W S Gouley then exhibited a peach pit which he said constituted a contribution to the subject of *Foreign Bodies in the Alimentary Canal* A gentleman, 71 years of age, had removed it from his rectum three months after it had been swallowed It was an inch and a quarter in length, seven eighths of an inch in breadth, and eleven sixteenths of an inch in thickness The case was interesting from the fact that this large and sharp pointed body caused no pain or distress whatever in passing through the intestinal canal Dr Gouley then related a case which occurred in his service at Bellevue Hospital The patient was a man suffering from delirium tremens who died soon after admission, and at the autopsy the pericardium was found filled with flaky lymph When the heart was lifted up a metallic substance was felt, and on opening the œsophagus, this proved to be a plate with two teeth attached Dr Gouley also mentioned a number of instances, mostly taken from Eve's Surgical Cases, in which enormous objects such as forks, spoons, and egg-cups, were swallowed, and in some instances passed successfully through the body One of these was a case occurring in 1807, in which a patient swallowed a teaspoon, which was successfully extracted one month afterward by Dr Samuel White, of Hudson, New York, who performed laparotomy, made an incision in the ileum, and, after removing the spoon, sewed up the intestine and the external abdominal wound

Dr John H Hinton said that a negro in his employ once swallowed a peach pit, and having taken a dose of castor oil passed it by the anus the next day, thus affording a remarkable example of an extremely rapid passage of a large foreign body through the alimentary canal

Dr Lewis A Sayre referred to a number of interesting cases occurring in his own experience, some of which illustrated the use of the bristle or umbrella probang, and the President, Dr C A Leale, told of the successful passage of a two cent piece through the intestinal canal of an infant 9 months old Dr Sayre said that for a considerable time he had supposed that the bristle probang was original with him, but had afterwards learned that the same device had previously been used by a medical officer in the British East India Service

The Secretary, Dr Porter, related a case recently reported by Dr C B Hutchings, of California, in which an open penknife passed successfully through the alimentary canal, the patient, a young man of 20, being advised to eat principally of such food as mush and buckwheat cakes, in order to distend the bowels and prevent their being injured in the passage of the knife through them He also referred to the case reported recently to the New York Surgical Society by Dr A G Gerster, in which a metallic button three quarters of an inch in diameter was swallowed by an infant 6 months old, and became imbedded between the trachea and œsophagus

Dr E S F Arnold referred to the celebrated case of Stephenson, Jr, the famous engineer, who swallowed a half sovereign, which passed into the trachea, and finally lodged at the bifurcation of the latter Sir Benjamin Brodie and others tried in vain to remove it, but at length it occurred to Sir Charles Aston Key to place the patient on an inclined plane, with his head down A sharp blow was then given upon the soles of the feet, and the plan proved so efficacious that the coin was jerked completely out of his mouth Dr Arnold also told of a case full of jack knives in every stage of decomposition and absorption, all of which came from a sailor who was ambitious to emulate the feats of a juggler whom he once saw at Liverpool He lived for nearly two years after commencing the practice of swallowing jack knives, and at the autopsy the knives and parts of knives were found in various portions of the intestinal canal

At the meeting of the Academy of Medicine, held May 20, Dr Edward G Janeway read a memoir of the late Dr Gaspar Griswold, and also a paper on the diagnosis of diseases of the heart

On the 19th the Alumni Association of the Woman's Hospital held its second meeting, when a number of interesting papers were read, and in the evening Dr T Gaillard Thomas tendered the Association a reception at his new and beautiful residence on Madison Avenue, just completed, which proved to be a most delightful house warming

The statement made in the New York letter published in THE JOURNAL of May 1st, that a Fellow of the New York Academy of Medicine who was interviewed by a certain member of the Council told that gentleman to "go to h—ll," proves, after all, to be incorrect It is learned on the highest authority that the Fellow referred to was perfectly courteous in all that he said, and that no language in any way approaching the character of that reported was used during the interview Your correspondent would not, of course, have mentioned the matter at all had he not secured the alleged facts in a direct manner, and from, as he supposed, an absolutely reliable source It is now evident, however, that the latter was misinformed, and as it is his aim to present only the simple truth, and that no injustice should be done any one by him, he makes this correction with pleasure

The proposed amendment to the constitution providing that the Academy may suspend or expel a Fellow for "the commission of any act which unfavorably affects the character of the medical profession or the interests of the Academy," will probably be acted on at the first meeting in June

P B P

NECROLOGY

GREENBURY R HENRY, M D

Dr Greensbury Ridgely Henry, of Burlington, Iowa, died on May 14, 1885, of disease of heart and lungs Dr Henry was the son of Dr John Flournoy and Lucy S (Ridgely) Henry, and was born at Hopkinsville, Christian County, Ky, on September 28, 1828

He obtained his education at Jacksonville, Ill, studied medicine with the late Prof Gross, and graduated at the Medical College of Louisville on March 5, 1849 He entered upon the practice of his profession in Burlington in 1850, and soon established an enviable reputation for learning and skill in his profession, a reputation that increased with his years He was well known throughout the State as a leading member of the profession For several years he was a member of the School Board of Burlington, re elected again and again, giving evidence of the public estimation of his peculiar fitness for the place The State also honored him with the appointment as trustee of the Hospital for the Insane—this position he held at the time of his death

Aside from his superior professional qualification and attainments, and his great worth as a healer of the ills of his fellow men, he was a liberal and energetic citizen, ready at all times to invest his earnings in public enterprises, and thus aid and promote the growth of the City of which he was a most valuable citizen

Dr Henry was a man of bright intellect, a high sense of honor, and undoubted integrity He was a physician of learning and skill, always thoughtful and kind, particularly to the younger members of the profession He was a warm and steadfast friend, a thoroughly good man In 1850 he was married to Catherine Chambers, of Jacksonville, Ill She survives him with several children The Board of Trade, the Des Moines Medical Society, the School Board and several other organizations held special meetings and passed resolutions of respect for the memory of Dr Henry, and attended his funeral

MISCELLANEOUS

Wisconsin State Medical Society —This Society will hold its annual session of 1886 in Madison on June 1st and 2d Many papers of interest are announced The railroad rates are full fare going and one fifth returning, on presentation of certificates of attendance from the Secretary

Prevention of the Introduction of Contagious Diseases —In order to assist local authorities in the maintenance of quarantine against the introduction of infectious diseases, as provided in Section 4792, Revised Statutes, the act of April 29, 1878, and appropriation acts authorizing the President to maintain quarantine at points of danger, the President has determined to establish, by means of the vessels of the Revenue Marine, a National patrol of the coast of the United States, so far as it may be practicable under existing law and consistent with the performance of the other duties confided to that service

The following regulations will be observed relative to the inspection of vessels If a vessel be found with sickness on board, or in a foul condition, she will be directed to proceed to quarantine station herein before indicated, and the revenue marine officer will immediately notify the proper quarantine officer In such case no person will be permitted to board the vessel until the medical officers in charge of the quarantine shall have given the usual permit Should the pilot or master of a vessel, when hailed, report cases of recent or present sickness on board the revenue officer will not board, but will send her immediately to quarantine

Quarantine officers will be recognized as follows, viz Medical officers are acting assistant surgeons of the Marine Hospital Service in charge of Gulf, South Atlantic, Cape Charles, or Delaware Breakwater quarantines, or any officer of said service on duty at any port on the interior rivers, the Great Lakes, or Pacific coast, and all quarantine officers acting under proper State or local authority

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY FROM MAY 15 1886 TO MAY 21 1886

Capt F W Elbrey, Asst Surgeon, sick leave of absence still further extended one year on surgeon's certificate of disability (S O 115, A G O, May 17, 1886)

Capt Wm F Carter, Asst Surgeon, granted leave of absence for one month, to take effect about June 1, with permission to apply for an extension of one month (S O 55, Dept Tex, May 11, 1886,)

Capt John M Banister, Asst Surgeon, assigned to duty as Post Surgeon, Ft Canby, W T (S O 75, Dept Col, May 8, 1886

First Lieut C B Ewing, Asst Surgeon, relieved from duty at Ft Leavenworth, Kan, and ordered for duty as Post Surgeon, Ft Supply, Ind Ter (S O 48, Dept Mo, May 13, 1886)

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U S NAVY DURING THE WEEK ENDING MAY 27 1886

Law, H L, Surgeon, ordered to the U S R S "Wabash,"

Hawke, J A, Surgeon, detached from U S R S "Wabash" and await orders to sea

Ogden, F N, Asst Surgeon, detached from U S S 'New Hampshire" and wait orders

Baker, J W,, Asst Surgeon, ordered for examination preliminary to promotion

Woodruff, Charles E, commissioned Asst Surgeon in the Navy May 17

Henry, Charles P, commissioned Asst Surgeon in the Navy May 18

ADDRESS IN SURGERY

THE PRESENT STATUS OF ABDOMINAL SURGERY

BY N SENN, M D,
OF MILWAUKEE, WIS,
ATTENDING SURGEON TO THE MILWAUKEE HOSPITAL PROFESSOR OF THE PRINCIPLES AND PRACTICE OF SURGERY AND CLINICAL SURGERY IN THE COLLEGE OF PHYSICIANS AND SURGEONS CHICAGO, ILL CHAIRMAN OF THE SURGICAL SECTION OF THE AMERICAN MEDICAL ASSOCIATION FOR 1886

(Concluded from page 598)

VIII *Gastrotomy* —The indications for gastrotomy have multiplied with the advances of modern aggressive surgery The following are conditions for which the operation has been performed

1 Extraction of foreign bodies 2 Malignant disease of œsophagus 3 Non malignant stricture of œsophagus 4 Cicatricial stenosis of pylorus Alsberg has collected 107 cases in which the operation was done with a view to establish a permanent gastric fistula for the following conditions Carcinoma 72, syphilitic stricture 2, cicatricial stenosis 16 Of this number, 24 patients survived the operation for more than thirty days Of 22 cases proving fatal soon after the operation, 12 died of diffuse peritonitis, and 3 of phlegmonous inflammation of the abdominal walls

Gastric Fistula —When the operation has for its object the formation of a gastric fistula, it is of some importance to know at what point the stomach can be opened most advantageously by interfering least with its functional capacity The majority of operators have had recourse to Fenger's incision, about two inches below and parallel to the left costal arch Sédillot recommends an incision which should correspond to a point over the middle of the anterior surface of the stomach, claiming that the subsequent traction upon the cicatricial band in this locality would be reduced to a minimum, at the same time there would be no risk of injury to any important blood-vessels Larger argues in favor of making the fistula as near the cardiac end of the stomach as possible, and nearer the lesser than the greater curvature of the organ Berger and Championniere assert that clinical experience and post mortem examinations have shown that the opening is usually made near the pyloric orifice of the stomach, irrespective of the particular method of operation selected by the surgeon They also believe that a fistula in this locality does not impair the functional result When a gastric fistula is to be established, the operation should be done in two sittings The preliminary operation consists in making abdominal section stitching the parietal peritoneum to the skin, thus protecting the soft tissues against phlegmonous inflammation by contact with infectious substances, and fastening the anterior surface of the stomach with Lembert's sutures to the margin of the wound, so as to secure adhesions between the visceral and parietal peritoneum before the organ is opened After two or three days firm adhesions have formed, when the operation is completed, by making a small incision through the wall of the stomach Experience has shown that when the incision is large, it is difficult to prevent the escape of the contents of the stomach through the fistula even by ingenious contrivances, while a small opening is readily kept closed by a well fitting compress

1 *Extraction of Foreign Bodies* —When a foreign body has become lodged in the stomach, and its presence can be ascertained by a well defined complexus of symptoms, or by physical examination, no time should be lost in removing it by gastrotomy, as the foreign body may produce death by interfering with gastric digestion or by producing perforation Under these circumstances the operation is completed by suturing the wound in the stomach after the extraction of the foreign body, in the same manner as an intestinal wound, using the precaution to apply a double row of sutures to secure more efficient and perfect coaptation of the margins of the wound and serous surfaces Absolute and complete physiological rest of the organ is an essential condition for obtaining primary union in the shortest space of time Gussenbauer removed, by gastrotomy, a sword blade 27 ctm in length and 2 ctm in breadth The patient, unfortunately died of septic peritonitis, due to a perforation of the posterior wall of the œsophagus 14 ctm above the cardiac orifice of the stomach, and another perforation in the fundus of the stomach 1 ctm in width Billroth removed successfully a set of false teeth in the same manner, and the patient recovered without any untoward symptoms That the stomach may become the receptacle of strange and most disgusting substances is well illustrated by the cases recently reported by Schœnborn and Thornton, where gastrotomy was successfully performed for the removal of large masses of hair Both patients were hysterical females In Schœnborn's case the mass of hair weighed 281 grammes That these cases are not so exceedingly rare is shown by Thornton, who has collected eight recorded cases

where post-mortem examination revealed that the presence of hair in the stomach produced death without a correct diagnosis having been made or surgical relief attempted

Malignant Disease of Œsophagus —The results obtained by gastrotomy for the purpose of prolonging life in cases of carcinomatous stenosis of the œsophagus are not such as to entitle the operation to the dignity of a justifiable procedure, and yet it must be a source of comfort to the surgeons who continue to perform it to know that the mortality which attends it has greatly decreased since the antiseptic treatment of wounds has been introduced Zesas, for instance, has collected all cases of gastrotomy before and since the antiseptic treatment of wounds was practised During the preantiseptic period, thirty one operations were performed, with the result that only in one case was life prolonged by the operation (Jones)

Of 131 cases operated upon under antiseptic precautions, 28 terminated favorably as far as the operation was concerned In 104 cases carcinoma of the œsophagus furnished the indication for the operation, of which only 17 recovered from the immediate effects of the operation With such a fearful mortality, it becomes a serious question whether the operation is ever justified under the circumstances Zesas, as the result of his investigations, advises that the operation should be performed early, before the patient has been prostrated from the effects of the disease It behooves the conscientious surgeon to ask himself the question Am I justified in submitting a patient suffering from an incurable affection to an operation of such gravity, which at best can prolong life only for a short time? Science, statistics and humanity answer with a positive and unqualified "*No*"

2 *Non Malignant Stricture of Œsophagus* –In non-malignant stricture of the œsophagus, not amenable to more conservative treatment, gastrotomy should be performed, with a view of securing a new inlet for food into the stomach, and for the purpose of affording a more direct route of treating the stricture So far, the operation has been performed by Caponotto, Fagan, Schede, Cérenville, MacNamara, Davies Colley, and Bryant Fagan's two cases died In Schede's and Cérenville's cases, the principal and direct object of the operation—dilatation of the stricture—was not realized The same applies to MacNamara's case Davies Colley's and Bryant's cases were successful in every respect, as the dilatation of the stricture was accomplished and the permeability of the œsophagus was restored, so as to warrant the closure of the fistula

Caponotto's case deserves special mention as it illustrates in an admirable manner the indications for the operation, the method of performing it, and its results The operation was performed at Turin, September 19, 1884 The patient was a boy, five years of age, who had swallowed by mistake sulphuric acid, five months before the operation Soon after the accident, symptoms of stricture appeared He ate and drank with a good appetite, but vomited everything a few minutes after, and in consequence had become greatly emaciated The finest olive pointed bougie could not be passed through the stricture The abdomen was opened at the usual place for a gastrotomy, and the parietal peritoneum united with the skin, and a continued catgut suture that caught only the serous and muscular coat of the stomach, was made to fix the stomach to the wound An antiseptic dressing was applied On the fifth day the stomach was opened and food introduced directly into the stomach The patient improved rapidly The next step was to dilate the stricture, which was done by combined dilatation by means of sounds introduced both through the stomach and œsophagus After one month's treatment, the œsophagus was permeable to food, and the opening in the stomach was closed by another operation Four months subsequently the boy died of tubercular meningitis The autopsy showed that the stomach was slightly adherent to the abdominal wall at the site of the operation The stricture had its location about two ctm above the cardiac orifice, as was shown by a white circular cicatrix

Loreta's method of digital dilatation in non malignant pyloric strictures is deserving of confidence, and the results so far obtained merit imitation of the procedure

3 *Cicatricial Stenosis of the Pylorus* —In the operative treatment of cicatricial stenosis of the pylorus, the surgeon can resort to gastrotomy with subsequent gradual or forcible dilatation of the stricture, pylorectomy, or gastro enterostomy According to Zesas, gastrotomy for pyloric stenosis has been performed twenty seven times with eleven recoveries In these cases, the object of the operation is limited to the direct treatment of the stricture through the gastric wound or fistula If, after opening the stomach, the stricture can be efficiently overcome by rapid digital dilatation, the visceral and abdominal wounds can be closed If, however, this object is not obtained, a permanent gastric fistula must be established for subsequent gradual dilatation, until the permeability of the organ has been restored, when the fistula is closed by another operation It is only proper to remark that the operative treatment of cicatricial pyloric stenosis should be limited to extreme cases of narrow strictures with great dilatation of the stomach, where simpler measures, as a carefully regulated diet, irrigation of the stomach, etc , have proved ineffective in affording relief and maintaining nutrition

IX *Pylorectomy* —It is only a few years ago since Billroth announced to the world the feasibility of partial excision of the stomach for malignant disease by a successful operation upon a human being The members of the medical profession throughout the entire civilized world were unanimous in their admiration of the man who had achieved what appeared to be the greatest triumph of modern surgery The method of operating was modified and improved by other operators, and in a short time the medical journals teemed with accounts of new cases from different sources At the present time we are in a position to decide upon the *justifiability* of the operation In studying the statistics of the cases so far reported, even the most enthusiastic advocate of the operation must feel that the expectations which had been anticipated have not been realized. The science and art of surgery have both been enriched through the labors of many a bold and enthusiastic operator who have demonstrated the feasibility of pylorectomy, but the results obtained must also satisfy every conscientious surgeon that the time has come when the operation should be at least temporarily abandoned until improved methods of diagnosis will enable us to recognize cancer of the stomach early enough to be amenable to surgical treatment.

1. *Malignant Disease.*—Fourteen cases of pylorectomy for cancer operated upon by Billroth were analyzed by von Hacker as to the pathological conditions and the results which were obtained. He divided them into three classes: 1. No adhesions, disease limited to the coats of the stomach. 2. Slight adhesions which were readily separated. 3. Extensive adhesions and metastatic tumors in adjacent organs. Only two of the patients belonged to the first class, one remained well one and three fourths of a year and the other three and one-half years after the operation. In the latter case a tumor returned in the abdominal wall and another in the inguinal region which were removed. The second class embraced seven cases, three died soon after the operation, of the remaining four three died four, ten and twelve months after operation from return of the disease, the fourth suffered from return of the disease six months after operation. The five cases represented by the third class died from the immediate effects of the operation. It can be therefore seen that a favorable result can only be hoped for in cases coming within the limitation of the first class where the disease is circumscribed and has not passed beyond the limits of the stomach. Every one must admit the difficulties which surround the diagnosis at this early stage of the disease, and the unwillingness of the patient to submit to such a grave operation when he is comparatively free from suffering, elements which in accordance with Billroth's own experience would limit operations to exceptional cases. Such statistics in the practice of the most eminent surgeon should definitely settle the question in the mind of any surgeon whose humanity has not succumbed to his morbid desire for transient fame.

Statistics from other sources can show no better results. In sixty-one cases of pylorectomy collected by Dr. Winslow, of Baltimore, 50 per cent. have died of shock within twenty six hours, and of the cases which have recovered not one has lived for three years without recurrence of the disease at the site of the operation. Kramer has collected eighty-two pylorectomies with sixty one deaths. In seventy-two cases the operation was done for carcinoma, fifty five died soon after the operation, of the remaining seventeen only one proved a complete success. It is a source of congratulation to the surgeons of this country that the statistics above quoted are made up almost exclusively of foreign material. While the American surgeon is anxious and ready to adopt all modern innovations and improvements, in this particular instance he has shown a degree of conservatism worthy of his reputation in that direction. When the time has arrived when we shall be able to make an early positive diagnosis of malignant disease of the stomach, pylorectomy will be resuscitated and will find a ready adoption and a hearty welcome on American soil.

2. *Ulcer of the Stomach.*—Rydygier was the first to apply pylorectomy to the treatment of gastric ulcer. He excised a simple ulcer of the pyloric extremity of the stomach with a portion of the head of the pancreas, which was intimately adherent to the posterior surface of the stomach. The ulcer had given rise to stenosis and dilatation of the stomach for which the operation was undertaken. He affirms that resection of a portion of the stomach is a justifiable procedure in arresting hæmorrhage from a perforating ulcer of this organ. Czerny treated successfully a case of perforating ulcer of the stomach by making an incision through the anterior wall through which the ulcer was made accessible to direct operative treatment. The ulcer was excised and the visceral wounds closed. Recovery was complete and permanent. According to the statistics of Kramer pylorectomy has been performed ten times for contracting ulcer of the stomach with four recoveries and six deaths. Cicatricial contraction at the site of operation necessitated a second operation in one case in less than a year after the excision. The danger of secondary cicatricial stenosis would rather tend to indicate the superiority of gastro-enterostomy as a primary operation in these cases, and more particularly so if the ulcer or cicatrix is situated in the narrowest portion of the stomach, the pyloric orifice.

X. *Gastro enterostomy.*—This operation was devised by Wolffler as a substitute for pylorectomy in that class of cases where after an exploratory incision it is found impossible to extirpate the diseased pylorus. The operation is performed with a view to re-establish the permeability of the digestive tract by securing a new outlet to the stomach through the medium of a fistulous communication between it and an adjacent loop of the duodenum or upper portion of the jejunum. An incision is made through the anterior wall of the stomach, the margins of which are accurately stitched to a corresponding incision in the intestine by two rows of sutures applied in the same manner as in cases of enterectomy. As compared with pylorectomy this operation is easier of execution, affords a wider range of application, and implies the infliction of less traumatism, while, on the other hand, it has the disadvantage that the pathological conditions which necessitated the operation are left unchanged.

1. *Malignant disease.*—The mortality following this operation is much less than after pylorectomy. According to von Haeker, Billroth has performed gastroenterostomy nine times in cases of cancer of the pylorus where extirpation could not be practised, of this number five died from the immediate effects of the operation, and four survived the operation and were improved for a short time. Kramer gives an account of sixteen gastroenterostomies for malignant disease of the stomach with ten deaths soon after the operation, one patient died four weeks after from the effects of secondary tumors, the remaining five

onths In one case Billroth and gastroenterostomy simul patient After the excision of the intestines and stomach es and a new outlet for the d by gastroenterostomy The five weeks after the operation nts of the operation it will be t disease of the stomach it has in those grave and desperate was found impossible, hence we nanent results, and although the after pylorectomy, it is question lts that can be obtained by it—ths of alleviation—will compen ate risks of life incident to the

nt stricture of the pylorus.—The ly assign the proper sphere of to the treatment of grave cases of loric stenosis The exclusion of a estine from the digestive tract by of a new pylorus by gastroenteros erfere with the proper maintenance the operation in these cases must be only as a palliative but also as a e The results obtained in this class eed encouraging Kramer has col s, of which three recovered In one ases, a man 20 years of age, the diag e of *ulcus pylori* with cicatricial ste the abdomen was opened the stomach rmously dilated Nothing further was lominal incision was closed As the he patient continued he begged that ation should be performed The abdo ned again and a communication between and duodenum was established by Wolf on, and at the time the case was reported was doing well From the results already must be conceded that gastroenterostomy ecognized as an established and legitimate n the surgical treatment of non malignant nosis

odenostomy.—This operation was devised nbuch in 1880 for cases of inoperable ste he pylorus As the name indicates, it con e formation of an external permanent duo stula for the purpose of introducing food into the intestinal canal It was intended s where the general debility of the patient preclude the propriety of the more grave oper f pylorectomy The operation has been per by Southam and Robertson, but both patients n the day of operation It is not probable e operation will be again repeated

Jejunostomy.—In view of the great mortality lorectomy and gastroenterostomy for malignant e, Pearce Gould planned and executed the ation known as jejunostomy The object for n the operation is performed is the same as in enostomy, only that the intestinal fistula is made lower portion of the intestinal tract at a point re the mesentery is of sufficient length to permit the bowel to be easily drawn forward and stitched to the wound The patient was 43 years of age, whose vital powers were near to fatal exhaustion An incision was made in the median line from an inch below the xiphoid cartilage to within an inch of the umbilicus The disease was found to implicate the pyloric end of the stomach the commencement of the duodenum and mesenteric glands The great omentum was pushed upwards and the upper end of the jejunum was drawn forward and stitched to the margin of the wound with a double row of silk sutures The remaining portion of the wound was closed in the usual manner The patient was nourished by rectal enemata and Slinger's nutrient suppositories On the second day a small incision was made into the bowel through which an ounce each of cream and peptonized beef tea was injected The patient continued very restless and became worse and died of exhaustion sixty six hours after the operation The necropsy showed that the intestine had formed firm adhesions to the wound throughout and that no inflammation had followed the operation

From the experience furnished by this case he believes an incision through the left linea semilunaris would be preferable to the median incision The suture should be so placed that the part of the intestine [illegible] in the wound is that portion exactly opposite the mesentery The opening in the bowel should be across the axis of the intestine, and only long enough to admit the nozzle of a syringe The food should be administered through the fistula in only small quantities at a time and gradually increased When larger quantities are injected they should be given very slowly, so as to allow of their being mixed with the biliary, pancreatic, and intestinal secretions and to prevent distension of the bowel The food should be fluid and acid in reaction, the best articles being cream and peptonized milk and beef tea

Golding Bird performed a similar operation for the same indications some two months later without being aware of Gould's operation The bowel was opened on the third day, when food was administered solely through the fistula When the meal exceeded ten ounces it produced indigestion, in smaller quantities digestion and absorption appeared to be performed in a satisfactory manner The patient improved considerably in health until the ninth day, when through an error of feeding him some food passed into the abdominal cavity, and he died in twelve hours The reporter pointed out that by this operation duodenal digestion could be assured, and there was, for physical reasons, less chance of regurgitation than after gastrotomy, and that the procedure required less interference, in its performance, with other viscera than gastroenterostomy

Interesting as these operations may be from a surgical and physiological standpoint, it is to be hoped that in the future their application will be limited to experiments on the lower animals I have alluded to the different forms of "ostomies" for malignant disease to show how extensively the principles of abdominal surgery have been applied in laudable attempts to afford relief after the disease had passed

beyond the reach of radical measures As a matter of course the results have been so unsatisfactory that future attempts in the same direction should be abandoned as incompatible with the true aim and advancement of abdominal surgery

XIII *Splenectomy* —Accumulated experience appears to have definitely settled the indications for this operation As the result of a study of thirty cases of splenectomy, Credé has come to the following conclusions

1 Adults tolerate removal of spleen without permanent ill results 2 Extirpation of the spleen produces a temporary disturbance in blood production 3 The diminution in blood production is corrected by a vicarious action of other blood producing organs, the thyroid gland and the medullary tissue in bone 4 The physiological function of the spleen consists in effecting a transformation of the white into red blood-corpuscles

During the past year a new case of splenectomy for leukæmia has been reported by Rydygier The extirpated organ weighed six pounds The patient, a woman 31 years of age, died on the following day of hæmorrhage from the abdominal wound The ligature on the main blood vessels involved held perfectly, and Rydygier ascribed the hæmorrhage to imperfect coagulation dependent upon the altered condition of the blood This case brings the total number of deaths from the operation up to eighteen, of which sixteen were of hæmorrhage and two from shock Thus far the only successful case of splenectomy for leukæmia is that performed by Franzolini

As the pathology of splenic leukæmia remains to be explained and the mortality after extirpation has been so fearful, it would appear almost criminal to increase the sad statistics by adding new cases to the number of failures

Splenectomy for visceral injury of the organ can show a splendid record, as of twenty cases collected by Zesas of partial or complete removal of a prolapsed spleen all recovered

Credé extirpated the spleen successfully for cystic disease The incision was made along the outer margin of the rectus muscle on the left side from the costal arch to the crista ilii The pedicle was ligated and the stump dropped into the abdominal cavity The patient, a female, became more and more anæmic for a number of weeks Four weeks after the operation the thyroid gland became swollen and tender The gland returned to its normal condition with the general improvement of the patient a few weeks later Five years after the operation Crede reported his patient as remaining well The temporary change in the blood had passed away and no abnormal tumefaction of any of the blood producing organs could be found

Billroth extirpated a sarcomatous spleen with four ctm of the tail of the pancreas in a woman 43 years of age who had noticed the tumor for seven years The growth had been rapid for the last two years The tumor was firmly adherent to the omentum, small intestines and pancreas, the latter organ was divided with Paquelin's cautery The operation was not followed by any serious symptoms During the third week a microscopical examination of the blood showed a slight increase of the white blood corpuscles The patient was feeling well four weeks after the operation The numerous extirpations of the spleen made by Zesas on animals have demonstrated that it is not an essential organ and that its physiological function in the production of blood-corpuscles is adequately performed by vicarious organs, so that we can safely include splenectomy for visceral injuries and local diseases of the spleen among the well established legitimate surgical procedures

XIV *Surgery of the Gall Bladder* —Recently the gall bladder has been made a favorite object of operative treatment As patients suffering from affections of this organ usually come under the treatment of the physician at first, a brief consideration of the improvements in the surgical treatment of affections of this organ will be of great interest to every physician It requires no argument to show that surgical treatment should not be resorted to as an *ultimum refugium*, but to secure a good result the operation when required should be done before the patient's strength is too much reduced An early operation is the more justifiable as statistics have shown that operations upon the gall bladder are among the safest and most satisfactory within the domain of abdominal surgery

Although the feasibility of the surgical treatment of affections of the gall bladder was indicated by J L Petit and Thudichum, it was applied in practice almost simultaneously by Sims and Kocher in 1878 Sims completed the operation at one sitting, the patient died on the eighth day Kocher made a preliminary operation by stitching the gall bladder to the margins of the wound so as to secure adhesions between it and the peritoneum before resorting to incision and drainage The patient recovered In the absence of positive signs and symptoms, indicative of biliary obstruction, it is exceedingly important to resort to a most careful examination in determining the existence of an over distended gall bladder The anatomical location of the tumor, its relation to surrounding organs, and its connection with the under-surface of the liver are important elements in the differential diagnosis Mr Taylor, of Birmingham, who has had ample opportunity to examine cases of enlargement of the gall bladder with Mr Tait, describes a diagnostic line which appears to be of great value in determining the existence or absence of a distended gall-bladder "This line is to be traced from the normal position of the larger end of the gall bladder near the tip of the cartilage of the 10th rib on the right side, to the opposite side of the abdomen, crossing the middle line slightly below the umbilicus In the direction of this line a distended gall bladder will naturally lie" In view of the comparative safety of an exploratory operation this should be preferred to the more doubtful expedients of exploratory puncture and sounding of the gall-bladder, in all cases where a positive diagnosis cannot be made without resorting to these latter diagnostic measures, which cannot be said to be free from danger or to furnish sufficient information upon which to base a positive diagnosis

beyond the reach of radical measures As a matter of course the results have been so unsatisfactory that future attempts in the same direction should be abandoned as incompatible with the true aim and advancement of abdominal surgery

XIII *Splenectomy*—Accumulated experience appears to have definitely settled the indications for this operation As the result of a study of thirty cases of splenectomy, Credé has come to the following conclusions

1 Adults tolerate removal of spleen without permanent ill results 2 Extirpation of the spleen produces a temporary disturbance in blood production 3 The diminution in blood production is corrected by a vicarious action of other blood producing organs, the thyroid gland and the medullary tissue in bone 4 The physiological function of the spleen consists in effecting a transformation of the white into red blood-corpuscles

During the past year a new case of splenectomy for leukæmia has been reported by Rydygier The extirpated organ weighed six pounds The patient, a woman 31 years of age, died on the following day of hæmorrhage from the abdominal wound The ligature on the main blood vessels involved held perfectly, and Rydygier ascribed the hæmorrhage to imperfect coagulation dependent upon the altered condition of the blood This case brings the total number of deaths from the operation up to eighteen, of which sixteen were of hæmorrhage and two from shock Thus far the only successful case of splenectomy for leukæmia is that performed by Franzolini

As the pathology of splenic leukæmia remains to be explained and the mortality after extirpation has been so fearful, it would appear almost criminal to increase the sad statistics by adding new cases to the number of failures

Splenectomy for visceral injury of the organ can show a splendid record, as of twenty cases collected by Zesas of partial or complete removal of a prolapsed spleen all recovered.

Credé extirpated the spleen successfully for cystic disease The incision was made along the outer margin of the rectus muscle on the left side from the costal arch to the crista ilii The pedicle was ligated and the stump dropped into the abdominal cavity The patient, a female, became more and more anæmic for a number of weeks Four weeks after the operation the thyroid gland became swollen and tender The gland returned to its normal condition with the general improvement of the patient a few weeks later Five years after the operation Crede reported his patient as remaining well The temporary change in the blood had passed away and no abnormal tumefaction of any of the blood producing organs could be found

Billroth extirpated a sarcomatous spleen with four ctm of the tail of the pancreas in a woman 43 years of age who had noticed the tumor for seven years The growth had been rapid for the last two years The tumor was firmly adherent to the omentum, small intestines and pancreas, the latter organ was divided with Paquelin's cautery The operation was not followed by any serious symptoms During the third week a microscopical examination of the blood showed a slight increase of the white blood corpuscles The patient was feeling well four weeks after the operation The numerous extirpations of the spleen made by Zesas on animals have demonstrated that it is not an essential organ and that its physiological function in the production of blood-corpuscles is adequately performed by vicarious organs, so that we can safely include splenectomy for visceral injuries and local diseases of the spleen among the well established legitimate surgical procedures

XIV *Surgery of the Gall Bladder*—Recently the gall bladder has been made a favorite object of operative treatment As patients suffering from affections of this organ usually come under the treatment of the physician at first, a brief consideration of the improvements in the surgical treatment of affections of this organ will be of great interest to every physician It requires no argument to show that surgical treatment should not be resorted to as an *ultimum refugium*, but to secure a good result the operation when required should be done before the patient's strength is too much reduced An early operation is the more justifiable as statistics have shown that operations upon the gall bladder are among the safest and most satisfactory within the domain of abdominal surgery

Although the feasibility of the surgical treatment of affections of the gall bladder was indicated by J L Petit and Thudichum, it was applied in practice almost simultaneously by Sims and Kocher in 1878 Sims completed the operation at one sitting, the patient died on the eighth day Kocher made a preliminary operation by stitching the gall bladder to the margins of the wound so as to secure adhesions between it and the peritoneum before resorting to incision and drainage The patient recovered In the absence of positive signs and symptoms, indicative of biliary obstruction, it is exceedingly important to resort to a most careful examination in determining the existence of an over distended gall bladder The anatomical location of the tumor, its relation to surrounding organs, and its connection with the under-surface of the liver are important elements in the differential diagnosis Mr Taylor, of Birmingham, who has had ample opportunity to examine cases of enlargement of the gall bladder with Mr Tait, describes a diagnostic line which appears to be of great value in determining the existence or absence of a distended gall-bladder "This line is to be traced from the normal position of the larger end of the gall bladder near the tip of the cartilage of the 10th rib on the right side, to the opposite side of the abdomen, crossing the middle line slightly below the umbilicus In the direction of this line a distended gall bladder will naturally lie" In view of the comparative safety of an exploratory operation this should be preferred to the more doubtful expedients of exploratory puncture and sounding of the gall-bladder, in all cases where a positive diagnosis cannot be made without resorting to these latter diagnostic measures, which cannot be said to be free from danger or to furnish sufficient information upon which to base a positive diagnosis cases lived for several months. In one case Billroth performed pylorectomy and gastroenterostomy simultaneously upon the same patient. After the excision of the pylorus the end of the intestines and stomach were closed with sutures and a new outlet for the stomach was established by gastroenterostomy. The patient was doing well five weeks after the operation. From the above accounts of the operation it will be seen that for malignant disease of the stomach it has been resorted to only in those grave and desperate cases where excision was found impossible, hence we cannot speak of permanent results, and although the mortality is less than after pylorectomy, it is questionable if the best results that can be obtained by it—a few weeks or months of alleviation—will compensate for the immediate risks of life incident to the procedure.

2. *Non-malignant stricture of the pylorus.*—The future will probably assign the proper sphere of gastroenterostomy to the treatment of grave cases of non-malignant pyloric stenosis. The exclusion of a short space of intestine from the digestive tract by the establishment of a new pylorus by gastroenterostomy will not interfere with the proper maintenance of health, hence the operation in these cases must be looked upon not only as a palliative but also as a curative measure. The results obtained in this class of cases are indeed encouraging. Kramer has collected four cases, of which three recovered. In one of Rydygier's cases, a man 20 years of age, the diagnosis was made of *ulcus pylori* with cicatricial stenosis. When the abdomen was opened the stomach was found enormously dilated. Nothing further was done, the abdominal incision was closed. As the sufferings of the patient continued he begged that another operation should be performed. The abdomen was opened again and a communication between the stomach and duodenum was established by Wolfler's operation, and at the time the case was reported the patient was doing well. From the results already obtained it must be conceded that gastroenterostomy should be recognized as an established and legitimate operation in the surgical treatment of non-malignant pyloric stenosis.

XI. *Duodenostomy.*—This operation was devised by Langenbuch in 1880 for cases of inoperable stenosis of the pylorus. As the name indicates, it consists in the formation of an external permanent duodenal fistula for the purpose of introducing food directly into the intestinal canal. It was intended for cases where the general debility of the patient would preclude the propriety of the more grave operation of pylorectomy. The operation has been performed by Southam and Robertson, but both patients died on the day of operation. It is not probable that the operation will be again repeated.

XII. *Jejunostomy.*—In view of the great mortality of pylorectomy and gastroenterostomy for malignant disease, Pearce Gould planned and executed the operation known as jejunostomy. The object for which the operation is performed is the same as in duodenostomy, only that the intestinal fistula is made in a lower portion of the intestinal tract at a point where the mesentery is of sufficient length to permit the bowel to be easily drawn forward and stitched to the wound. The patient was 43 years of age, whose vital powers were near to fatal exhaustion. An incision was made in the median line from an inch below the xiphoid cartilage to within an inch of the umbilicus. The disease was found to implicate the pyloric end of the stomach, the commencement of the duodenum and mesenteric glands. The great omentum was pushed upwards and the upper end of the jejunum was drawn forward and stitched to the margin of the wound with a double row of silk sutures. The remaining portion of the wound was closed in the usual manner. The patient was nourished by rectal enemata and Slinger's nutrient suppositories. On the second day a small incision was made into the bowel through which an ounce each of cream and peptonized beef tea was injected. The patient continued very restless and became worse and died of exhaustion sixty-six hours after the operation. The autopsy showed that the intestine had formed firm adhesions to the wound throughout and that no inflammation had followed the operation.

From the experience furnished by this case he believes an incision through the left linea semilunaris would be preferable to the median incision. The sutures should be so placed that the part of the intestine presenting in the wound is that portion exactly opposite the mesentery. The opening in the bowel should be across the axis of the intestine, and only long enough to admit the nozzle of a syringe. The food should be administered through the fistula in only small quantities at a time and gradually increased. When larger quantities are injected they should be given very slowly, so as to allow of their being mixed with the biliary, pancreatic, and intestinal secretions, and to prevent distension of the bowel. The food should be fluid and acid in reaction, the best articles being cream and peptonized milk and beef-tea.

Golding Bird performed a similar operation for the same indications some two months later without being aware of Gould's operation. The bowel was opened on the third day, when food was administered solely through the fistula. When the meal exceeded ten ounces it produced indigestion, in smaller quantities digestion and absorption appeared to be performed in a satisfactory manner. The patient improved considerably in health until the ninth day, when through an error of feeding him some food passed into the abdominal cavity, and he died in twelve hours. The reporter pointed out that by this operation duodenal digestion could be assured, and there was, for physical reasons, less chance of regurgitation than after gastrotomy, and that the procedure required less interference, in its performance, with other viscera than gastroenterostomy.

Interesting as these operations may be from a surgical and physiological standpoint, it is to be hoped that in the future their application will be limited to experiments on the lower animals. I have alluded to the different forms of "ostomies" for malignant disease to show how extensively the principles of abdominal surgery have been applied in laudable attempts to afford relief after the disease had passed

beyond the reach of radical measures As a matter of course the results have been so unsatisfactory that future attempts in the same direction should be abandoned as incompatible with the true aim and advancement of abdominal surgery

XIII *Splenectomy*—Accumulated experience appears to have definitely settled the indications for this operation As the result of a study of thirty cases of splenectomy, Credé has come to the following conclusions

1 Adults tolerate removal of spleen without permanent ill results 2 Extirpation of the spleen produces a temporary disturbance in blood production 3 The diminution in blood production is corrected by a vicarious action of other blood producing organs, the thyroid gland and the medullary tissue in bone 4 The physiological function of the spleen consists in effecting a transformation of the white into red blood corpuscles

During the past year a new case of splenectomy for leukæmia has been reported by Rydygier The extirpated organ weighed six pounds The patient, a woman 31 years of age, died on the following day of hæmorrhage from the abdominal wound The ligature on the main blood vessels involved held perfectly, and Rydygier ascribed the hæmorrhage to imperfect coagulation dependent upon the altered condition of the blood This case brings the total number of deaths from the operation up to eighteen, of which sixteen were of hæmorrhage and two from shock Thus far the only successful case of splenectomy for leukæmia is that performed by Franzolini

As the pathology of splenic leukæmia remains to be explained and the mortality after extirpation has been so fearful, it would appear almost criminal to increase the sad statistics by adding new cases to the number of failures

Splenectomy for visceral injury of the organ can show a splendid record, as of twenty cases collected by Zesas of partial or complete removal of a prolapsed spleen all recovered

Credé extirpated the spleen successfully for cystic disease The incision was made along the outer margin of the rectus muscle on the left side from the costal arch to the crista ilii The pedicle was ligated and the stump dropped into the abdominal cavity The patient a female, became more and more anæmic for a number of weeks Four weeks after the operation the thyroid gland became swollen and tender The gland returned to its normal condition with the general improvement of the patient a few weeks later Five years after the operation Credé reported his patient as remaining well The temporary change in the blood had passed away and no abnormal tumefaction of any of the blood producing organs could be found

Billroth extirpated a sarcomatous spleen with four ctm of the tail of the pancreas in a woman 43 years of age who had noticed the tumor for seven years The growth had been rapid for the last two years The tumor was firmly adherent to the omentum, small intestines and pancreas, the latter organ was divided with Paquelin's cautery The operation was not followed by any serious symptoms During the third week a microscopical examination of the blood showed a slight increase of the white blood-corpuscles The patient was feeling well four weeks after the operation The numerous extirpations of the spleen made by Zesas on animals have demonstrated that it is not an essential organ and that its physiological function in the production of blood-corpuscles is adequately performed by vicarious organs, so that we can safely include splenectomy for visceral injuries and local diseases of the spleen among the well established legitimate surgical procedures

XIV *Surgery of the Gall Bladder*—Recently the gall bladder has been made a favorite object of operative treatment As patients suffering from affections of this organ usually come under the treatment of the physician at first, a brief consideration of the improvements in the surgical treatment of affections of this organ will be of great interest to every physician It requires no argument to show that surgical treatment should not be resorted to as an *ultimum refugium*, but to secure a good result the operation when required should be done before the patient's strength is too much reduced An early operation is the more justifiable as statistics have shown that operations upon the gall bladder are among the safest and most satisfactory within the domain of abdominal surgery

Although the feasibility of the surgical treatment of affections of the gall bladder was indicated by J L Petit and Thudichum, it was applied in practice almost simultaneously by Sims and Kocher in 1878 Sims completed the operation at one sitting, the patient died on the eighth day Kocher made a preliminary operation by stitching the gall bladder to the margins of the wound so as to secure adhesions between it and the peritoneum before resorting to incision and drainage The patient recovered In the absence of positive signs and symptoms, indicative of biliary obstruction, it is exceedingly important to resort to a most careful examination in determining the existence of an over distended gall bladder The anatomical location of the tumor, its relation to surrounding organs, and its connection with the undersurface of the liver are important elements in the differential diagnosis Mr Taylor, of Birmingham, who has had ample opportunity to examine cases of enlargement of the gall bladder with Mr Tait, describes a diagnostic line which appears to be of great value in determining the existence or absence of a distended gall-bladder "This line is to be traced from the normal position of the larger end of the gall bladder near the tip of the cartilage of the 10th rib on the right side, to the opposite side of the abdomen, crossing the middle line slightly below the umbilicus In the direction of this line a distended gall bladder will naturally lie" In view of the comparative safety of an exploratory operation this should be preferred to the more doubtful expedients of exploratory puncture and sounding of the gall bladder, in all cases where a positive diagnosis cannot be made without resorting to these latter diagnostic measures, which cannot be said to be free from danger or to furnish sufficient information upon which to base a positive diagnosis

The surgical treatment of the diseases of the gall bladder at present includes three distinct and well defined methods of operation, viz

1 Cholecystotomy with or without the formation of an external biliary fistula

2 Cholecystectomy or excision of the gall bladder

3 Duodeno cholecystotomy or the formation of a new communication between the gall bladder and the duodenum

1 *Cholecystotomy* —At the present time the majority of operators are in favor of finishing the operation at one sitting According to Keen the incision should be made, as a rule, over the centre of the tumor and parallel to the costal arch It should be at least three inches in length and enlarged, if need be, afterward All hæmorrhage must be carefully arrested before opening the peritoneum Through this opening the gall-bladder and common duct are explored by the introduction of two fingers, or if necessary, the whole hand to ascertain the condition of the swelling, its relations to surrounding organs, and so far as possible, the character of its contents If a calculus is found in the common duct an attempt should be made to push it into the duodenum, if this cannot be accomplished it should be forced back into the gall-bladder If no stone is found present, a distended gall-bladder alone is a sufficient indication for incision and drainage The evacuation of the gall bladder is done by aspiration and its wall is subsequently cut to the extent of an inch or more After incision care must be exercised to prevent escape of bile into the peritoneal cavity The margins of the visceral wound are carefully stitched to the abdominal wound and the cavity of the gall bladder, and its duct emptied of their contents

Immediate closure of the gall bladder after removal of its contents, was first suggested by Spencer Wells as appropriate in cases where the surgeon can satisfy himself of the patency of the biliary passages This suggestion was carried out by Mr Meredith, of London, who closed the incision in the gall bladder after the extraction of three calculi, by means of a fine silk thread, introduced as a continuous suture, and inverting the edges of the peritoneal coat The abdominal incision was closed in the usual way, no drainage being employed This patient died in forty-eight hours with suppression of urine At the autopsy the incision in the gall-bladder was found securely closed and quite impervious to fluid He remarks on this method of operating as follows "As regards the method adopted—of dispensing with drainage—I do not feel inlined to recommend it, although there appears to me no reason why it should not succeed in a favorable case, provided always that it was possible to ascertain that no obstruction remained in the ducts This, of course, constitutes the chief difficulty, and may be impossible, so that, on the whole, I believe that the more usual plan of draining the gall bladder should be preferred, at all events in the majority of instances"

Mr Tait has expressed a similar opinion on this subject He states distinctly that it cannot always be accertained with certainty that the common duct is patent, and if this should not be the case the periodical contractions of the gall bladder might cause a giving way of the sutures, and extravasation of bile into the periodical cavity That these fears are not without foundation is well illustrated by the case of cholecystotomy reported by Dr Parkes The case reported by Dr Bernays during the last year on the other hand, demonstrates the advantage of suturing the gall bladder and dispensing with drainage, as the patient recovered in a remarkably short time without any untoward symptoms and without the inconveniences of a temporary fistula As in the majority of cases the safety of the patient is enhanced by the formation of an external biliary fistula, which also enables the surgeon subsequently to treat the interior of the gall bladder and the bile ducts, should this be required it is evident that immediate closure of the gall bladder has only a limited sphere of usefulness, and is applicable only in exceptional cases where the permeability of the biliary passages can be demonstrated at the time of operation As in all other abdominal operations, the results obtained by Mr Tait in the surgical treatment of diseases of the gall bladder stand unsurpassed and preeminent He performed cholecystotomy twenty-one times with as many recoveries From different sources Dr J McF Gaston has collected thirty three cases of cholecystotomy with a mortality of 27 7 per cent, nine having died

2 *Cholecystectomy* —Ligation of the cystic duct and extirpation of the gall bladder was introduced as a substitute for cholecystotomy by Langenbuch He claims for his operation that it is not attended by any of the risks incident to incision and evacuation of the gall bladder, and that in cases of recoveries from the operation it prevents the possibility of a recurrence of the disease and that the chances of a permanent biliary fistula are never incurred He has performed the operation five times, with two deaths, one from acute œdema of the brain, and the other from an ulcerous perforation of the cystic duct Two successful cases are reported by Thiriar and one by Corvoisier

Mr Tait prefers cholecystotomy to cholecystectomy, as being an easier and safer operation, and in case a recurrence of the disease makes a second operation necessary, he claims that the first operation makes the second easier It can be done readily and without any danger through the adherent cicatrix, without any risk of opening the peritoneal cavity

Duodeno-Cholecystotomy —This term signifies an operation for uniting the gall bladder and duodenum, by an opening between them It has been suggested as a surgical procedure almost simultaneously by Harley and McF Gaston, in cases of impermeability of the common bile duct, while the cystic duct is permeable, or may be rendered so by surgical means In regard to such an operation, Harley says "The triumph of modern surgery would be to establish an artificial fistula between the gall bladder and the duodenum For then not alone would the pent up bile be removed, but the disturbances arising from the non admittance of bile into the intestines would likewise be at the same time overcome I am not quite sure if, in these days of antiseptic surgery the operation is not practicable, for I can see no reason why the adjacent surfaces of the gall-bladder and duodenum should not be eroded by potassa fusa and speedily stitched together" Dr Gaston has made this subject an object of patient and persevering experimentation In summing up his results he says "Out of fifteen subjects only three dogs finally survived the primary operation, yet it will be observed that the results of attachment of the gall-bladder to the duodenum and firm union by adhesive inflammation between their surfaces, and the formation of a fistulous opening through this septum, which affords a communication between their cavities"

The *feasibility* of this operation has been demonstrated on animals, but its adoption in practice as a legitimate, justifiable operation can only be expected after a more safe and expedient method of accomplishing the object has been devised, and its applicability has been demonstrated more satisfactorily on animals

XV *Injuries and Surgical Affections of the Liver* —The idea of treating injuries and some of the diseases of the liver by surgical means is not a new one, as Ceccherilli credits his countryman, Zambeciari, with having made experiments on animals with such a view as early as 1680 Experiments and clinical observation have shown that injuries of the liver under favorable circumstances are not only repaired, but that in some unaccountable and as yet unexplained manner, loss of substance is replaced by regeneration Thus Ceccherilli reports, among a number of operations, a very interesting case where he performed excision of a portion of the liver, with the gall-bladder, in a large hunting dog, with Paquelin's cautery The operation was bloodless, and the animal recovered without any untoward symptom The animal remained perfectly well, and was killed 226 days after the operation The autopsy showed a cicatrix in the liver at the site of the operation, and that the organ had been restored to its former shape and size, as was ascertained by comparison with the liver of a dog of the same size From the results of his experiments he advises that in no case should more than one-third of the size of the liver be excised To prevent or arrest hæmorrhage he prefers the actual cautery to the elastic ligature and pressure forceps

1 *Wounds* —That gunshot wounds of the liver are not necessarily fatal, even if no active surgical treatment is resorted to, has been well established by a number of cases where the bullet was found encysted in the organ, without having given rise to any symptoms during life, years after the injury had been received Thus Bilguer found a bullet encysted in the liver four months after the accident Guthrie, Paroisse, and Thompson have each reported a case where, on autopsy, the bullet was found in the gall-bladder, the patient having died with other affections These cases and the results of experiments are only mentioned with a purpose to show that with proper surgical treatment injuries of the liver would not be attended by such great mortality as has been the case on the expectant plan of treatment The two great dangers attending visceral injury of the liver are hæmorrhage and extravasation of bile into the peritoneal cavity In subcutaneous lacerations of the liver, if the symptoms are such as to indicate internal hæmorrhage of a serious nature, the only chance to save life would be to perform abdominal section, and to control the hæmorrhage by direct measures, as without such interference the patient would be almost certain to die of peritonitis, even if he recovered from the effects of hæmorrhage

From the anatomical structure of the liver it is easy to conceive that the arrest of hæmorrhage from this organ is not an easy task Ligation is out of question If the wound has a regular outline and involves the border of the liver accurate coaptation of the wound surfaces with catgut sutures traversing the entire thickness of the organ, would offer a fair chance of controlling the hæmorrhage The needle should be round and not quite as large as the thread of the catgut, so that the punctures would not give rise to additional sources of hæmorrhage If the wound is irregular or located in such a manner as to render suturing impossible, the actual cautery can be used to advantage If this fails to control the hæmorrhage, we have still left at our disposal one of the most reliable and safest means of arresting parenchymatous or venous hæmorrhage, in the aseptic tampon—a tampon made of iodoform gauze If an aseptic tampon is to be successful in arresting hæmorrhage, an aseptic condition of the wound is indispensible In subcutaneous and consequently, aseptic, wounds of the liver rendered accessible to treatment with the tampon by abdominal section, there would be no objection in plugging the wound permanently, closing the abdominal cavity with the exception of an opening for a drainage-tube as near as possible at a point opposite to the visceral wound

Drainage in these cases is required on account of possible extravasation of bile taking place by filtration through the tampon In the course of time the aseptic foreign material would become encysted The use of the tampon for arresting hæmorrhage from the liver was advised by Thesen as early as 1795, and more recently by Brotherson, Demme, and Volkmann In penetrating wounds of the abdomen with visceral lesion of the liver, the same means may be resorted to in arresting hæmorrhage and guarding against extravasation In incised wounds suturing, if possible, should be resorted to, in gunshot wounds the aseptic tampon, with drainage As prolapsed portions of the liver are also usually contused, reposition, as a rule, is contraindicated, and such portions are better removed with a Paquelin's cautery

As aseptic foreign bodies may become encysted in the liver as well as in other parts of the body, no additional injury should be inflicted in order to effect their removal All such attempts are attended by an increase of hæmorrhage and, from the friable nature of the substance of the liver, unless the greatest care is exercised an increase of traumatism is inevitable On these accounts a faithful effort should be made to secure an aseptic condition of the wound so as to obtain the most favorable condition for the healing of the wound, and the formation of a capsule around the foreign body in all cases where extraction cannot be readily accomplished

2. *Abscess and Echinococcus Cysts.*—The treatment of abscess of the liver and echinococcus cysts by abdominal section is based on the same principles which embrace all the precautions which are necessary to obtain adhesion between the parietal and visceral peritoneum at the site of incision. The recognized plan of treatment consists in making an exploratory incision through the abdominal wall over the most prominent part of the swelling, to ascertain the presence or absence of adhesions. If the peritoneal cavity is found obliterated, the operation is finished at once by incising and draining the abscess or cyst. If, on the other hand, no adhesions are found, the surface of the liver is exposed and the wound packed with iodoform gauze and an antiseptic dressing applied, which is allowed to remain for four to five days, until adhesions have formed, when a second operation is made to evacuate the contents of the swelling by incision. If the abscess or cyst is centrally located, and a considerable portion of healthy liver tissue is interposed between it and the external surface of the organ, it is advisable to make the incision with Paquelin's cautery, so as to prevent unnecessary or dangerous loss of blood. Echinococcus cysts are frequently located upon the upper surface of the liver, and on this account are inaccessible to treatment by abdominal section. In such cases the practice of attacking them through an opening in the chest, as has been successfully done by Israel and Volkmann, recommends itself as the safest and most expedient operation.

XVI. *Surgery of the Pancreas.*—The surgery of the pancreas belongs to the future. The physiological function of this organ requires further investigation for a more intelligible interpretation of symptoms when the seat of injury or disease. The only pathological conditions of the pancreas which have been made an object of surgical treatment are cysts. A number of successful cases of this kind are on record where a permanent cure was obtained by laparo-pancreatotomy, or the formation of an external pancreatic fistula. In only one case did the fistula remain permanently, in all the rest the secretion diminished gradually, and ceased definitely with the healing of the fistula. It is to be hoped that the symptomatology of different lesions of the pancreas will be made a special object of careful study and investigation, so that in the future we may be able to recognize and classify the different diseases of this remote organ during life, so that we may be able to resort to laparotomy in affections which may be amenable to direct surgical treatment.

XVII. *Laparo-nephrectomy.*—Although statistics have shown that lumbar nephrectomy is a much safer operation than laparo-nephrectomy, the latter has a a legitimate sphere in cases of large tumors of the kidney, which cannot be removed through a lumbar incision. This operation also enables us to examine the opposite kidney at the time of operation, an advantage which is considered of sufficient importance by Thornton to give this operation the preference in all cases where nephrectomy is intended. Bruntzel has lately removed successfully a fibroma of the capsule with the entire kidney weighing 37½ pounds, by abdominal section, in a woman thirty-three years of age. The tumor had reached this enormous size in five years. It reached from the ensiform cartilage to the symphysis pubis, distending the abdomen equally in all directions. Tympanitic resonance on percussion on both sides of the tumor. Palpation and exploratory puncture showed that the structure of the tumor was firm and solid. An incision was made the entire length of the linea alba. On opening the abdomen the tumor came into view covered by peritoneum, which was divided over the whole length of the tumor. The tumor was enucleated with the kidney and the pedicle, which was composed of the renal vessels, was tied, and after division dropped into the abdomen. The cavity was drained towards the lumbar region and the divided peritoneum sutured. Notwithstanding that a fecal fistula formed subsequently, the recovery of the patient was complete and permanent.

By a similar operation, Hicquet extirpated successfully a retroperitoneal sarcoma, which was intimately connected with the kidney with the latter organ in a girl six years of age. In this case the renal artery and vein were tied separately. For the extirpation of malignant tumors of the kidney or its immediate vicinity, laparo-nephrectomy affords a better chance for a thorough removal of diseased tissue and for controlling hemorrhage, and on these accounts should be preferred to the lumbar operation. Whenever practicable, the integrity of the peritoneal cavity should be restored by suturing, and, if required, drainage established in the lumbar region.

XVIII. *Laparo-nephrotomy.*—This operation is indicated in all cases of hydro-nephrosis and pyo-nephrosis, where from the size of the swelling, or on account of adhesions, lumbar nephrectomy cannot be performed. It is also preferable to the lumbar operation where a positive diagnosis cannot be made, between disease of the kidney and other fluctuating tumors of the abdomen, and in some instances extirpation of a hydronephrotic or pyonephrotic kidney is contraindicated by a disease of the opposite kidney or the general debility of the patient.

XIX. *Tumors of Omentum Majus.*—Tumors of the large omentum give rise early to pain or a sensation of discomfort, by causing traction upon the transverse colon by their weight. As a rule, tumors of this structure are found in the umbilical region, and have no connection with adjacent organs, hence they are movable in all directions, except downward. The differential diagnosis between omental and intestinal tumors in the same region rests upon the complexus of symptoms caused by the latter group, from their anatomical location interfering more or less with the functions of the intestinal tract. In the examination of an omental tumor, it must be remembered that it is in immediate contact with the anterior abdominal wall, consequently its presence will be indicated by an area of dulness on percussion corresponding to the size of the tumor. If the area of dulness remains permanent and unchangable, it would be an indication that the tumor has become adherent, or that the tumor is not omental but parietal.

Primary malignant disease of the omentum, if it could be recognized early, would offer most favorable conditions for successful radical extirpation by abdominal section Cystic tumors and echinococcus cysts are most favorably located for successful treatment by abdominal section and drainage

XX *Tumors of Mesentery* —Aggressive surgery is gradually but surely encroaching upon the most remote tissues within the abdominal cavity, thus extending the benefit to be derived from direct local treatment to the most distant pathological conditions

A few years ago, M Tillaux extirpated successfully from the mesentery a glandular tumor which had undergone degenerative changes The patient was a man, aged thirty one years, in excellent health, who was taken suddenly ill without apparent cause The most prominent symptom was a violent pain in the abdomen, which compelled him to remain immovable for about fifteen minutes The pain recurred after a short interval with unmodified intensity The following day the suffering continued in spite of anodynes, which were given freely He was now removed to the hospital where on examination a round tumor was found in the abdomen, which was thought to be a floating kidney The patient suffered with obstinate constipation and pain for twenty-five days, when the pain became paroxysmal and always aggravated when he attempted to take food He only obtained relief when he sat on his bed bent double, with his head resting on his knees At this time M Millard diagnosticated chronic invagination of the intestines About thirty-eight days from the beginning of the illness, abdominal section was performed by Tillaux The abdomen was opened sufficiently to permit the introduction of the hand, when he found a round tumor about the size of the head of a fœtus at term, situated on the right side of the mesentery which fastened the intestine to the spinal column The tumor was recognized as a cyst of the mesentery This was punctured and subsequently incised and evacuated from it caseous matter, resembling thick cream Catgut ligatures were then thrown around the base of it, tied, and then the whole of the tumor cut off above them The pedicle was touched with a strong solution of carbolic acid, the organs returned, and the wound closed The pain ceased promptly and the recovery of the patient was complete The histological examination of the tumor showed it to be composed of a lymphatic gland containing the products of caseous degeneration This case illustrates that it is comparatively safe to remove tumors of the mesentery by ligation or enucleation, while, on the other hand, extirpation of tumors requiring for their removal the excision of a corresponding portion of the mesentery is a vastly more serious and difficult operation

Wolffler reports a case of this kind In his case a fibroma of the mesentery weighing 1½ pounds was removed with the mesentery and a corresponding portion of the intestine 113 ctm in length The ends of the bowel were brought together with sutures The patient survived the operation only for twenty-four hours Wolffler suggests that in the future enterectomy in connection with extirpation of tumors of the mesentery should be followed by enterorrhaphy only in cases where the site of operation involves the movable portion of the bowel, as the cæcum, transverse colon, and sigmoid flexure, while in other localities no attempt should be made to unite the resected bowel, but the efforts of the surgeon should cease with the formation of an artificial anus That this advice is not tenable in all cases becomes apparent, as, for instance, if the tumor is located in the mesentery of the upper portion of the intestinal canal, the physiological exclusion of such a large intestinal surface would be incompatible with a proper maintenance of digestion, assimilation, and nutrition

My experience on animals in extirpating the pancreas has satisfied me of the tolerance of the small intestine to even extensive detachment of the mesentery If it can be accomplished without producing mechanical destruction of the bowel by flexion it would be advantageous to approximate the vascular supply by suturing the mesenteric wound This course also suggests itself as an important measure in preventing a defect in the mesentery which might subsequently become a source of internal strangulation Hamerton has collected eight operations done for extirpation of tumors of the mesentery of which only one appears to have recovered This case was operated upon by Sir Spencer Wells, who removed a tumor the size of an adult head A microscopic examination showed that the tumor was a spindle celled sarcoma In a recent communication in the London *Lancet* Mr Wells informs us that the patient has remained free from a recurrence of the disease and remains otherwise in good health since the date of operation, June, 1882 In all benign tumors of the mesentery enucleation should be preferred to excision so as to preserve intact as much as possible of the mesenteric circulation

There can be no question but that mesenteric detachment is more likely to be followed by gangrene of the bowel if enterectomy is performed than when the continuity of the intestinal tube is preserved

XXI *Retro peritoneal Tumors* —The extirpation of a retro peritoneal tumor by laparotomy must be looked upon as one of the most serious and difficult operations in surgery Aside of the unusual difficulties encountered in arriving at correct conclusions as to the exact seat and nature of tumors in the retro peritoneal space, the technique for their removal remains to be improved by future research and experimentation

Dr Homans has reported two cases of retro-peritoneal tumors removed by abdominal section In the first case the operation was performed for a myxolipoma in a man 39 years of age, the tumor had been growing for two and a half years The second patient was a woman 60 years of age, suffering from a lipoma The tumor was located in both cases in the right side In the first case another tumor was found in front and toward the left of the spine, which could not be removed Both patients died soon after the operation

In the first case the mesentery of the ascending colon was detached to gain access to the tumor Homans very properly warns against such extensive deprivation of vascular supply to the bowel in this particular locality He advises, under such circumstances, either enterectomy and enterorrhaphy, or the formation of a preternatural anus It would seem that in some of these cases, where the tumor is of moderate size, the operation would be easier, and the results better, if a lateral abdominal incision were made without opening the peritoneal cavity In approaching the tumor through the peritoneal cavity after dividing the overlying peritoneum, the enucleation of the tumor should be accomplished by the use of blunt instruments, and with special care to preserve the integrity of the mesenteric vessels so as to avoid, if possible, the necessity for enterectomy and enterorrhaphy

The foregoing fragmentary and imperfect sketch of the Present Status of Abdominal Surgery will, I hope, at least serve the purpose of impressing upon you the importance and magnitude of this, the most recent, department of surgery I have attempted to allude to the defects as well as the advances, the failures as well as the triumphs The results already obtained by the surgical treatment of injuries and diseases of the abdominal organs, are indeed gratifying, and bear abundant evidence of the good and faithful work which has been accomplished The greatest achievements of abdominal surgery, however, necessarily belong to the future This new territory, only so recently acquired by the surgeon, has been only partially explored New operations will be devised and old ones improved Diagnosis will be made more certain by a careful study of symptoms, a more thorough knowledge of physiology and pathology of the abdominal organs Experimental research will clear up many obscure points in the causation of disease, which will lead to new and improved methods of treatment With all these prospects before us, let us not remain idle Abdominal surgery is of American birth Let us cherish our own offspring The world holds us responsible for its healthy growth and development McDowell, Gross, Sims, the distinguished fathers of Abdominal Surgery, have left us in charge of an important and sacred trust Let us labor in this department honestly, unceasingly, zealously, as faithful guardians of the promising infant until it shall have attained vigorous, perfect manhood, a source of pride to its illustrious parents, a perpetual fountain of blessing to suffering humanity, and a priceless honor to American Surgery

---

A RAPID EVACUATOR FOR LITHOLAPAXY ACTING BY A CONTINUOUS CURRENT, ALSO A NEW METHOD OF ATTACHING FILIFORM GUIDES TO STRICTURE INSTRUMENTS[1]

BY EDMUND ANDREWS, M D , LL D ,
SENIOR SURGEON TO THE MERCY HOSPITAL CHICAGO

The operation of litholapaxy, or lithotrity at one sitting, derived much of its marvelous success from the improved rubber bulbs and metallic tubes devised by Bigelow for the evacuation of the fragments of stone Yet Bigelow's evacuators, and also those of Sir Henry Thompson, have this serious defect the rubber bulb makes suction only for an instant When it reaches the limit of its expansion, it suddenly stops the outward current from the bladder, and arrests *in transitu* a row of fragments of stone lying along the whole length of the tube, which at the next compression of the bulb are all thrown back into the bladder Thus a large part of the fragments are pumped out and in many scores of times before they finally escape, and the evacuating stage of the operation is tediously prolonged, often lasting thirty or forty minutes At the same time the inflamed bladder is irritated by the repeated forced expansions, and by the pelting of sharp fragments continually shot back into it

Obviously what is needed is a continuous current moving always in the same direction This idea has occurred to many persons, I presume, for since commencing investigations in this direction I have received letters suggesting analogous thoughts and plans from different physicians, especially from Dr W H Graves, of Lexington, Ill , and Dr M B Cochran, of Davenport, Iowa After calculating the mathematical forms and proportions best adapted to the end, and corroborating the conclusions by experiment, I have succeeded in having the following apparatus constructed by E H Sargent & Co , which evacuates the fragments with a rapidity much beyond my expectations It consists of the following parts

First, a double chambered evacuating tube represented in Fig 1, which may be either straight or curved The straight ones are the best They must be very carefully constructed as follows The straight part consists of a cylindrical tube of very thin metal with an outside diameter of 8½ millimetres, and terminating in a rounded tip having a fenestrum like Bigelow's This is the evacuating part, and it is made cylindrical with the largest admissible calibre, so as to permit the largest possible fragments to escape through it Its outer end is bent downward as in the cut, and terminates in a piece of rubber tube 9 centimetres long and 1 centimetre inside diameter, for a purpose presently to be mentioned

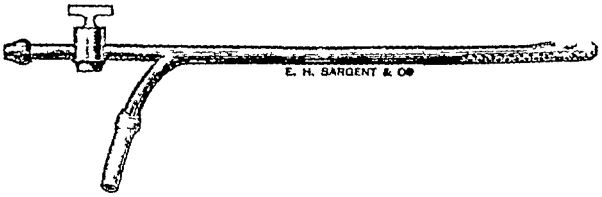

FIGURE 1

Along the under side of the straight portion of this outflow tube is soldered a thin concave semi cylinder making an inflow chamber which, so to speak, is wrapped half around the outflow tube, giving the whole an oval cross section with an outside circumference of about 31½ millimetres (see Fig 2) The diameter, A B, of the cylindrical part is 8½ millimetres, and the depth, B C, of the inflow chamber is 2 millimetres The inflow channel terminates in forty perforations, each 1 millimetre in diameter The

---

[1] Read before the Chicago Medical Society, May 17, 1886

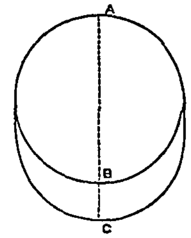

Figure 2

outer end of the inflow tube projects in a straight line beyond the curve of the outflow, and terminates in a cylinder 10 millimetres inside diameter and having a stopcock of the same calibre. Great pains must be taken by the manufacturer to have no drops of solder or other obstructing material in the narrow inflow chamber.

To the outer end of the inflow tube is attached a rubber tube with an inside diameter not less than 1 centimetre, and a length of about 3 yards. The further end of this rubber tube attaches to a metallic strainer large enough to admit without resistance all the water which will flow through the rubber tube. A disc of ordinary perforated sheet metal 3 inches in diameter, with orifices less than a millimetre, will transmit the requisite quantity of wash.

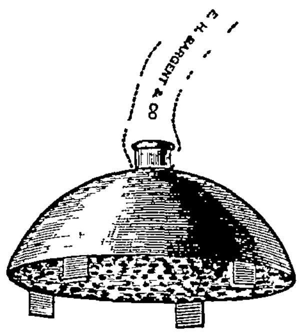

Figure 3

A bucket filled with warm carbolized water having a strength of 1½ per cent. is hung over the foot of the operating table at such a height that the surface of the water will be about forty two inches higher than the patient's pubis. The hydraulic pressure generated by this height will deliver through the tube a current swift enough to sweep the fragments out of the bladder very rapidly. A metallic guard prevents the rubber tube from being compressed where it rests upon the rim of the bucket. The method of use is as follows. The long syphon rubber tube is connected to the strainer, and the latter dropped into the bucket of warm carbolized water. The tube is filled and connected with the evacuator, the stopcock being closed.

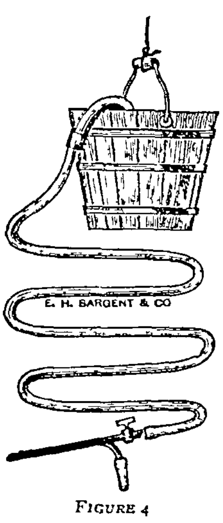

Figure 4

The patient is now anæsthetized, and the stone crushed in the usual way. When the comminution is thought to be sufficiently accomplished, the evacuator is inserted into the bladder with the fenestrum towards the patient's head, and held at a steep slope so that the tip presses the bottom of the bladder gently down towards the rectum, making a funnel-shaped depression into which the fragments tend to fall. Now turning the stopcock, the fluid is admitted, and rushing through the inflow division, it enters the bladder by the small perforations, sweeping the fragments rapidly around into the fenestrum of the outflow tube, thence outward into a basin placed between the patient's thighs. The current being continuous and always in one direction the evacuation is accomplished with remarkable rapidity. In a recent case in which I tried it, the fragments made by crushing a hard oxalate of lime calculus over one inch in diameter were almost completely swept out in ten seconds, when perhaps twenty-five minutes of churning to and fro with Bigelow's evacuator would scarcely have accomplished the same result. Some sixty seconds more of the current sufficed to remove the last minute particles remaining. Having observed the slowness of Bigelow's apparatus by using it in some thirty cases, I was deeply impressed by the shortening of the operation effected by means of the continuous current.

There is one obstacle which affects my own and Bigelow's evacuators alike. If the crushing of the calculus is not pretty thorough, several large pieces may roll against the fenestrum at once, and lodging against each other in an arched form, obstruct the outflow, or a single piece too large to pass may do the same thing. I meet this difficulty in a very simple way. The last four inches of the outflow pipe is of rubber. When the sudden scantiness of the stream shows that the fenestrum is blocked, the operator compresses the end of the short rubber outflow pipe between his thumb and finger, and then with the thumb and finger of the opposite hand suddenly compresses the tube just above. This forces a short but strong pulsation back into the bladder and dislodges instantly the obstructing fragments.

The wash should always be of warm carbolized water, to which, perhaps, a little cocaine might advantageously be added. The carbolized water blunts the irritability of the nerves of the bladder and thus prevents shock, while it also leaves the cavity in a thoroughly antiseptic condition and tends powerfully to prevent cystitis.

In addition to the apparatus just shown I beg leave to call attention to a new method of attaching filiform guides to stricture instruments. The methods of connecting them heretofore have been two. First, by a small female screw on the butt of the guide which fits a male screw on the tip of the instrument. As the whalebone guides have not been fitted in this fashion, the operator could only connect to one or two of the woven variety usually sold him with his instrument, and could use no others. The second method of connection has been by a small orifice or tunnel through a knob at the tip of the instrument, which slides over the whalebone guide and thus attempts to follow it through the stricture. The trouble

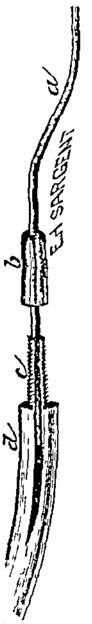

Figure 5
Enlarged
2 diam

with the tunnelled instruments is that in a tight stricture the whalebone clings so closely to the steel that frequently it will not slide It is greatly to be desired that a stricture cutter or divulsor should be capable of being attached to any guide whatever which is found to pass the stricture

The cut shows on an enlarged scale a plan which works well A is a filiform bougie, either woven or of whalebone B is a nut or female screw made to fit the split screw C The split extends a little distance into the staff of the instrument D, so as to give the two parts the elasticity of a spring, and the jaws are roughened so as to hold the bougie with a firm grip

In using the instrument, the surgeon tries his various filiforms until he finds one which passes the stricture Leaving it *in situ*, he slips the female screw or nut B upon the bougie, next opens the split screw and closes it upon the end of the bougie, and secures it by screwing on the nut B His guide is now firmly held, and will generally lead the instrument successfully through the stricture

MEDICAL PROGRESS

The Rectum in the Young —At the meeting of the Obstetrical Society of New York on, February 16, Dr Jacobi read a paper on this subject, of which the following is a brief synopsis The hollow of the sacrum being less curved in the child than in the adult, the rectum is shorter, straighter, and more uniform in shape, hence liquid or semisolid feces, after passing the sigmoid flexure in the infant, are rapidly evacuated In the embryo the intestine is formed in sections, the excess occurring in the descending colon and sigmoid flexure, the latter may have a length of even thirty cm , whereas in the adult it seldom exceeds twenty cm Because of the small size of the infantile pelvis the colon is thrown into folds, so that instead of one, there may be several flexures Clinically, the presence of the redundent intestine is of great interest, from the fact that it may give rise to difficulty in determining the true position of the sigmoid flexure, and may prevent the passage of the intestinal contents, leading to the erroneous diagnosis of complete obstruction The inflammatory conditions of the rectum, catarrhal, diphtheritic, etc , are of the same character as those in the adult A simple proctitis may result from the irritation caused by a foreign body, or may be due to syphilis or tuberculosis Periproctitis occurs rarely after typhoid and pyemia There is no instance on record of cancer of the rectum in an infant Complete fistula are rare in children and are difficult to cure, the incomplete variety are much more common The actual cautery is the only reliable agent to employ in treating them, it should be applied to the entire canal from without inwards

Dysentery —This may be sporadic, endemic, or epidemic The catarrhal and diphtheritic variety are interchangeable As a result of the inflammatory process, the mucous membrane often becomes necrotic Destruction of the glands, and subsequent cicatrization of the mucosa, and contraction of the bowel sometimes occurs The treatment is mostly local Pain in the hypogastrium may be relieved by cold or warm applications Opium is of great value, and is tolerated in full doses, it should be given by the mouth rather than in enemata The best astringents are tannin and gallic acid, lead, nitrate of silver, and iron—all to be given in small doses, but at frequent intervals Bismuth is a valuable remedy, which, in addition to its antifermentative action, serves to protect the mucous membrane In case of ulceration, local enemata should be used, injections of tepid salt solutions, flax-seed tea, etc , should first be given, in order to empty out the bowel, after which astringent solutions are to be introduced A one per cent solution of alum or tannin is generally useful Weak solutions of nitrate of silver (one or two per cent) may be used in subacute cases, but should be neutralized at once with salt-solution

Rectal Polypi —These vary in size from a pea to a hazel nut, or larger They may be single or multiple, sessile or pedunculated, their usual site being just above the internal sphincter They were first described by Stoltz in 1831, Bokay found them only in one out of 2,600 patients, but Dr Jacobi usually meets with three or four cases annually, and has treated about 100 cases, the ages of the patients ranging mostly from two to five years Among the symptoms noted were irregular defecation (mucus or blood sometimes being discharged), with accompanying tenesmus, especially when the polypus was near the internal sphincter or between the two sphincters A red mass might protrude from the anus, and repeated hæmorrhages were not uncommon, the last symptom being almost pathognomonic of polypus The growth is readily felt on introducing the index finger into the rectum, which can usually be accomplished without difficulty The treatment is simple, since the pedicle offers but a slight resistance, and may be tied and cut, or separated by torsion or evulsion, the loss of blood being insignificant Sessile polypi often give rise to no symptoms, and may be caused to shrink up and disappear by using astringent injections

Prolapse of the Anus or Rectum —These are only different degrees of the same pathological condition Weakness of the sphincter may be either congenital or acquired, the latter may result from overstraining as the result of an inflammatory process in the bladder or bowel, fistulæ, abscesses, polypi, etc The mildest form of prolapsus consists in a simple eversion of the anus, between which and the worst variety, in which three or four inches of the bowel protrude and are incarcerated, there are many intermediate forms The indications always are to reduce the prolapsed part, and to retain it in the proper position For the latter purpose a T bandage, or tamponing, with fixation of the nates, has been recommended, plugs of hard rubber or lead are used by others The cause of the prolapsus, whatever it is, ought to be eliminated. Polypi or vesical calculi should be removed, constipation and chronic diarrhœa should be cured. The child ought not to be allowed to defecate sitting upon a low stool, and each passage should be assisted by a large enema.

The swollen mucous membrane must be cleansed by frequent injections, and astringents be applied to it, a one per cent solution of nitrate of silver being recommended; the latter must be neutralized at once with salt-solutions as otherwise it may produce soreness of the rectum, and thus lead to tenesmus, which will increase the existing prolapsus. Excessive hyperemia may be relieved by applications of ice and a four per cent solution of cocaine. In exaggerated cases, the solid stick of nitrate of silver might be applied, or, better, still, the actual cautery, which may be applied longitudinally, transversely, or at several different points. If the sphincter is weak, an induced current, passed through the perineum, is beneficial, sulphate of strychnine being administered hypodermically in daily doses varying from $\frac{1}{60}$ to $\frac{1}{24}$ gr. Instead of the latter, an ointment composed of one part of extract of nux vomica and from twelve to twenty parts of fat or vaseline, may be introduced into the rectum.

Fissure of the Anus.—This is generally regarded as a rare affection in infants, but it is more frequent than is usually supposed. Kjelberg is the only writer who claimed that it is frequent during the first year of life. It generally appears as a narrow, reddish or grayish slit, observed on separating the margins of the anus, seldom extending beyond the sphincter, while the surrounding parts present a normal appearance. The fissure is extremely sensitive to the touch, and an examination frequently causes a contraction of the sphincter that is partly voluntary and partly spasmodic. A milder form of fissure may result from the rhagades of congenital syphilis, or from local skin erruptions. The more severe varieties are due to constipation or the passage of foreign bodies; the former condition may result from a congenital contraction of the sphincter, leading to an accumulation of feces in the ampulla, just above the point of constriction. As a rule, the fissure is situated at the posterior edge of the anus in the median line. The pain during defecation is intense and may last for several hours afterwards, so that the little patient's face becomes haggard and distorted; abdominal pain, tympanites, and other intestinal troubles may co-exist with cerebral irritation and sleeplessness—all of which symptoms may often disappear after a single dilatation of the sphincter. Vesical spasm and dysuria are not unfrequently due, not to the presence of a calculus, but to anal fissure.

Incontinence may occur instead of dysuria, not the paralytic form, but that in which small quantities of urine are passed at a time with tenesmus. In many children the symptoms may be more general; they are restless and fretful, lose their appetite, their sleep is disturbed, and they scream suddenly without any apparent cause. Their stools are frequent, but of the average daily amount and appearance. A polypus and fissure may rarely co-exist in the same patient after the first year of life; there will then be frequent discharges of blood, as well as excruciating pain in the region of the anus. The proper treatment of fissure consists in forcible and instantaneous dilatation of the sphincter, with or without anæsthesia, by the introduction of the two index fingers. The sphincter should be stretched until its fibres are distinctly felt to give way. Boyer advises deep incisions through the sphincter, but these may be followed by hæmorrhage, ulceration, and septic absorption.—*American Journal of Obstetrics*, April, 1886.

MASSAGE AS A THERAPEUTIC AGENT.—In a note on this subject DR. WILLIAM MURRELL says: It is no easy matter to say in what class of diseases massage proves most useful. Unfortunately, its employment has been advocated in many cases, for which it is essentially unsuited. Accurate diagnosis is of the utmost importance, and, the sphere of usefulness of this remedy will, with increased experience, become more accurately defined. My best results have been in infantile paralysis; and it was in consequence of the success achieved in certain obstinate cases of this disease, that my attention, as has been elsewhere stated, was directed to the subject. Progress is often slow, but the ultimate results are most satisfactory. The nutrition of the parts is maintained until new cells in the spinal cord take on the functions of those which have undergone degeneration, or have been destroyed. Massage is, undoubtedly, of much value in many cases of obstinate neuralgia, and succeeds admirably in some forms of muscular pain, such for example, as those described by the late Dr. Inman under the term "myalgia." There is a general concensus of opinion that it is well adapted for the treatment of chronic joint-affections; and most of those I saw treated by von Mosengeil were such as would, in this country, be considered incurable, or would drift into the hands of "bone-setters." There are some diseases of internal organs in which it is, undoubtedly useful. Not long ago, a gentleman, aged 68, came to me complaining of shortness of breath, and increasing disinclination to take exercise. He had been in business, and had led a most active and energetic life. Three or four years ago he retired, and, from that time, experienced a gradual falling off in health. His appetite was poor, his bowels were obstinately confined, and he was nervous and anxious about himself. He was found to have a loud apex systolic murmur, and the heart's action was weak and irregular. I suggested massage, which was carried out systematically four days a week, for a period of six weeks. He improved from the very first, and, before the conclusion of the course, was better than he had been for many months. His appetite returned; his hands and feet were warmer; the bowels became regular; he slept well at night; and his spirits improved in a most satisfactory manner. In other cases of obstinate constipation, especially in women, I have known massage of the abdomen do a great deal of good.

In a well-known group of symptoms from which women frequently suffer, massage is essentially useful. I recently saw a lady, aged 45, or thereabouts, a professional singer, who was laboring under the impression that she was going mad She was so nervous that she was quite unable to accept an engagement, although she had been constantly before the public, and had hardly missed a night for twenty years She told me she felt she was not to be trusted, and that, if left alone she would do herself or her children an injury She was afraid to go near an open window, so great was the temptation to throw herself out, and she even begged that the knives might be removed from the table at dinner These symptoms were greatly intensified after each monthly period, and she insisted that she was suffering from cancer, or some organic disease of the stomach or womb She was restless at night, and would often get up in the early morning, and walk for hours, until thoroughly exhausted She was given full doses of the bromides—a drachm, or more, four times a day—but with only temporary benefit Massage was then tried, and it seemed, to use her own expression, to soothe her, and calm her, and make her forget her troubles The case was a prolonged one, but now, at the expiration of three months, she is much better, and will soon be able to resume her professional duties In several other cases of restlessness and inability to sleep, the same method of treatment has proved efficacious

Dr Graham, of New York, speaks highly of massage in the treatment of neurasthenia He uses it for those "who, in spite of rest, change and medication, have become chronic neurasthenics, the result of business reverses, overwork, worry, loss of relatives, disappointed hopes, or as a sequel of some affection that has existed in some part of the system, but which has recovered or has become of secondary importance" These symptoms may be somewhat ill defined, but I have certainly found massage of the greatest use in what, for want of a better name, has been called "spinal nervous weakness," or neurasthenia spinalis"

In the treatment of corpulence associated with constipation, massage is of much value Some months ago I saw a lady, aged 38, who, as the result of much good living and little exercise, had become inordinately stout She was very short of breath, and was disinclined for exertion of any kind She had been fond of literary pursuits, but even those had lost their charm, and were irksome to her She was extremely irritable, and a source of trouble and anxiety to her friends and relatives Massage was prescribed, and in two months she lost a stone and a half in weight, and improved notably in other respects

For many forms of menstrual disturbance, massage may be safely prescribed I recently saw a young lady, aged 19, who suffered intensely at each monthly period, the pain being so severe, that hypodermic injestions of morphine had to be resorted to Massage of the abdomen and pelvis was prescribed, and from that time there was no return of the trouble Cazeaux has reported several similar cases, in detail In the convalescence from acute illnesses, this mode of treatment is a great help and comfort to the patient There can be no doubt that massage is a very valuable therapeutic agent, and is likely to yield good results in many complaints other than those I have roughly indicated —*British Medical Journal*, May 15, 1886

Effect of Bitters on Digestion —Dr Cheltsoff, chief of Professor Botkin's clinic, thinks that extracts of the so called "pure bitters," which are usually prescribed with the view of stimulating the secretion of gastric juice and of aiding digestion, so far from having any beneficial effect of that kind, are absolutely injurious, inasmuch as they retard the digestive functions He has made a series of experiments with extracts of aurantium, gentian, trifolium, absinthium, calumba, cascarilla, and quassia on (1) gastric digestion, and the secretion of gastric juice, (2) pancreatic digestion and the secretion of pancreatic juice, (3) the secretion of bile, (4) fermentation, and (5) nitrogenous metamorphosis The conclusions at which he arrived were that bitter extracts, even in small doses, interfere with artificial gastric digestion, and also with the gastric digestion of animals, but not to so great an extent Large doses of bitter extracts diminish the secretion of gastric juice, though small doses effect a slight and transitory increase of it, the digestive power of the fluid being, however, in all cases diminished Bitter extracts have no effect on the secretion of pancreatic fluid, but they nevertheless retard hypogastric digestion The action of bitter extracts on the secretion of bile is various, extract of absinthium, extract of trifolium, and large doses of extract of cetrarin, slightly increases it, usually at least, but not invariably, while extract of quassia, extract of calumba, and small doses of extract of cetrarin, have no effect at all Bitter extracts have no anti fermentative effect, and do not hinder suppuration Lastly, assimilation of nitrogenous substance is diminished by the use of these extracts —*Lancet*, May 15, 1886

A Case of Compulsory and Exclusive Backward Movement —In *La Rivista Clinica* of June, 1885, Dr Mazotti reports the following rare case An alcoholist, 66 years of age, was admitted into the hospital of Bologna for the treatment of scurvy After his recovery from this affection, it was found that in spite of the greatest efforts, he could only walk backward, and that after that he had to turn around his own axis These movements, of course, constantly imperilled his life He soon succumbed to pneumonia, and the examination of the brain showed an atheromatous condition of the vessels at the base We wonder that the inspection of the spinal cord was omitted, which might have given some clue for these peculiar symptoms —*Therap Gaz*, May 15, 1886

Photographing the Uterine Cavity —A Swiss physician describes a plan of introducing wadding tampons and laminaria tents into the uterus, by which he has succeeded in dilating the organ to such an extent as to be able, by means of reflectors, to get a complete view of the whole cavity in cases of carcinoma, fibrous polypi, fibromata, and endometritis Not being content with ocular inspection, he has also contrived to obtain photographs of the cavity —*Lancet*, May 15, 1886

A FOURTH YEAR OF MEDICAL STUDY—OF WHAT SHOULD IT CONSIST?

A very few of the medical colleges of this country advise a fourth year of medical study, but by none is it required The catalogues of *most* of these schools do not show that any students are enrolled in the four year course The studies taught in the three first years are just those that are required for graduation The studies of the fourth year consist of supplementary clinical work and in advanced instruction in some of the special branches of medicine

A fourth year of this character is not what most students wish They know that a year or eighteen months spent in a good hospital as house physician and surgeon will enable them to see more and learn more than they could in the fourth year at college The best students will therefore plan to graduate in three years and take their fourth year of clinical and practical instruction in the hospitals Poor students will not spend any more time in study than is required of them These are without doubt the reasons why fourth year courses have not yet become at all popular Three years is too short a time for a proper study of medicine unless the student comes to college well disciplined by previous study, and best of all by a certain amount of scientific study We would suggest, therefore, that in this country to day there is more need of a fourth year introduced at the beginning of the medical course than at the end of the present three years of graded study Such a course would meet the wishes of several classes of students

Frequently the question is asked by parents who have sons 18 or 19 years old desirous of ultimately studying medicine, who have not the means to give them a college education and who yet desire to prepare them a little better for the study of medicine, what and where can they study for a year or two? Many of our literary colleges and scientific schools have longer courses that are well adapted to such cases, but not short courses purposely planned for these students There is a still larger class of students who have a fair English common school education, who know nothing of scientific methods of study and who nearly waste the first year of their medical course in learning how to study As these form a very considerable proportion of the students at medical colleges, and not unfrequently some of the best, it would seem right that they should receive or be provided there with a year's course which should be preparatory to their further study The best of these certainly could readily be induced to take a year of preparation for medicine if a proper course was offered to them, and they would be much benefited thereby What is now most needed by a majority of the medical students is some preliminary, or rather preparatory, education

At least a good English education should be demanded as preliminary to taking up any course in a medical school The four year course that we would suggest would consist of a preparatory year of study and the three courses as now graded in our best colleges Graduates of literary colleges and scientific schools might well be admitted to the second year in this scheme without examination on the branches of the first year

With a good and a broad preparation the details of the study of medicine will be acquired most readily, and they will possess for the student much more interest Frequently students will applaud a lecture devoted to the circulation of blood through the heart as it is illustrated by various experiments or drawings, but when the same lecturer describes the chemical changes that occur in the blood while it passes through the lungs or through a muscle or other organ of the body, his words are devoid of interest, and often to the student of meaning Why is this? In the first place, the student does not appreciate the importance of the subject, in the second place, he is at the time studying elementary chemistry and is not prepared to understand the complex changes that the lecturer describes How much better could a student appreciate the existence of these chemical changes in connection with growth and life if, in a course on general biology, he had studied practically himself the comparatively simple changes effected by the growth of the yeast plant in the air and the medium about it This will illustrate in a measure the necessity for some preliminary knowledge of science A knowledge of chemistry, physics and general biology would throw a flood of light and interest on physiology and pathology Physics and comparative anatomy would bear a similar relationship to human anatomy, both normal and pathological Botany would be especially valuable to the student of materia medica

The subjects that might appropriately be studied during this proposed year would be chemistry, physics, general biology, elements of comparative anatomy, and botany In connection with chemistry there should be an abundance of practical work in the laboratory, and the use of the microscope should be taught in connection with the biological and anatomical studies

The objects that such a course would accomplish would be threefold First, it would give the student a scientific foundation upon which to build a medical education Second, it would make easier and more entertaining some of the most technical parts of medical study Third, it would teach the student scientific methods of thought and reasoning that would enable him better to appreciate science as applied to medicine Such a course would not be an appropriation of studies by a medical school that rightfully should be taught elsewhere, for during many years the medical curriculum in the best schools of the old world has included these branches and they rightfully belong in it

THE DRY TREATMENT OF SIDEWALKS

The visitor in Chicago at this season of the year, and until the snow falls in the autumn, is usually surprised to see the regularity with which the streets are sprinkled by the watering carts, and the equal regularity with which the sidewalks are never moistened except from the clouds The visitor sees it with surprise, and the residents see it and grumble It is not at all unusual to see men, going down town to business in the morning, crossing the street to avoid a cloud of dust which is being raised by an industrious sweeper in front of a dwelling or store, and then recrossing to escape suffocation from the dust raised by the emptying of a barrel of ashes into an ash bin (which generally has a prominent place on the sidewalk) This cloud raising process is usually gone through with three or four times a day, as the breezes with which Chicago is blessed will on no account allow all the dust and sweeping to be deposited in the gutter The dust raised by one sweeper is carried to the sidewalk of the next house, and into the open windows within the vicinity The clouds of dust which frequently pour forth from the door of a business house might sometimes cause a myopic person to raise an alarm of fire, and the smoke from a fire would be much more pleasant in the eyes and nostrils than the heterogeneous dust which salutes and envelops one twenty or thirty times in a walk of a mile

A certain amount of dust in a large city is unavoidable, but it does seem that with a large lake just outside the city limits enough water could be found to sprinkle the sidewalks before they are swept Dust which is chemically clean is unpleasant when deposited on the buccal, conjunctival or Schneiderian mucous membrane, but the typhoon of the desert has the odors of Araby compared with the compound which is sifted into one's nostrils from a butcher's shop or a fish market That the sidewalks are cleansed (?) in this manner is all the more surprising when one notes the manner of cleansing the windows A person takes a cup of water, and repairing to the edge of the sidewalk, or as near to it as possible, projects the water in the direction of the window, a pedestrian usually receiving a share of it After the windows are washed the dry process is applied to the sidewalk, and the window is again ready for the washing of the next day

Will the efficient Department of Health of Chicago look into this matter and see if it cannot be remedied? Dust in large cities, and in large quantities, is not only unpleasant but unwholesome It has been claimed that in times of cholera water should be withheld from the streets, as the cholera microbe will more quickly perish when kept dry But Chicago is now free from cholera, and even if it were not there could be no good reason why the streets should be sprinkled regularly, and the sidewalks kept dry with equal regularity

THE TREATMENT OF HYDATID DISEASE IN MAN

Such is the title of an interesting paper read by Dr W Gardner before a recent meeting of the South Australian Branch of the British Medical Association He classifies the treatment under the three heads of medicinal, expectant and surgical, but one may very properly class the medicinal treatment as expectant in the larger of cases The medicinal treatment can consist only in the administration of drugs which are supposed to cause the death of the parasite, and which must at the same time be innocuous to the patient, and before any conclusions can be drawn, says Dr Gardner, we must prove two things that a hydatid cyst is present in connection with some organ, which is not only very difficult, but absolutely impossible without tapping or aspiration (which may then be reasonably said to have assisted, if not actually produced the cure) 2 If a cure is supposed to have been effected by the use of drugs it is necessary to show the existence of a collapsed and retrograded cyst by post mortem examination And even should these things be done it would be entirely proper for a sceptical person to say that the life history of the hydatid renders it very probable that the death of the vesicle at a more or less remote time is but a natural ending At any rate it is found that among all the reported cases there is not one which may with any certainty be said to have been cured by purely medicinal treatment

We have said that the medicinal treatment may be properly classed as expectant, though the use of the term expectant in speaking of the treatment of hydatid cysts is rather foreign to the usual acceptation of the term, and is only applicable to those cases of cysts of the lungs which have ruptured spontaneously into a bronchus, and not to any unruptured cysts of the lung Of Davaine's 40 cases there were 15 cures and 25 deaths, and of the 15 cures 12 were from the expectant treatment Hearn has recorded 144 cases, with 62 cures and 82 deaths, 45 of the cures being from the expectant treatment, though it may be suspected that Davaine's cases are included in his table Many of Davaine's cases occurred during the early part of this century, when the diagnosis was probably less exact than to day Dr Gardner has records of 24 cases of hydatids of the lung with spontaneous rupture, with 22 recoveries so far as he has been able to keep track of the cases Bird has met with 150 cases of hydatid of the lung, but his monograph gives no statistical details But taking all the statistics at command, it seems that of 212 cases of spontaneous rupture 101 have recovered and 111 have died—less than 50 per cent of recoveries Bruen, in his article on "Pulmonary Hydatids" in Pepper's "System of Medicine," says that 30 or 40 per cent of cases terminate in recovery if the cysts spontaneously burst, death being caused in others by suppuration and exhaustion The very rational conclusion to which Dr Gardner comes is that the expectant method will only be applied to ruptured cysts which are causing little inconvenience, and are in process of cure, and cysts so situated as not to be amenable to surgical treatment

The surgical methods of dealing with hydatid cysts have been given so often they need not be detailed in this place Dr Gardner's general conclusions are that all hydatid cysts of the external surface of the body should, immediately upon the establishment of the diagnosis by the aspirator or hypodermic needle, be incised and the cyst removed, and that hydatids of the lung or abdomen should be first tapped to establish the diagnosis, and, if possible, to effect a cure A radical operation should be made on the appearance of suppuration or of opacity of the fluid He thinks that in the future we will best secure the safety of the patient by resorting to an early radical operation

Dr Frank Donaldson, Jr, is the author of the paper entitled "A Preliminary Account in Regard to Circulatory and Respiratory Changes observed in Animals placed in the Pneumatic Cabinet," an abstract of which was given in The Journal of May 22, p 579, and credited to Dr Frank Donaldson

SOCIETY PROCEEDINGS

CHICAGO MEDICAL SOCIETY

Stated Meeting, May 17, 1886

The President, E J Doering, M D,
in the Chair

Dr Edmund Andrews exhibited a

NEW EVACUATOR FOR LITHOLAPAXY, AND A FILIFORM GUIDE ATTACHMENT

(See page 626)

Dr W T Belfield opened the discussion by saying that the disadvantages of the ordinary evacuating apparatus mentioned by Dr Andrews were well recognized, and that the apparatus exhibited seemed adapted to remove them It possessed, however, one element of danger, namely, the possibility of undue distension of the bladder through sudden clogging of the exit tube In cases of concentric hypertrophy, where the bladder can contain only three or four ounces, the continuation of the powerful inflow might, if the exit were obstructed, cause serious damage Of course if the clogging is immediately discovered, a prompt use of the stopcock would prevent injury

As to the urethral instrument, he would wish to be sure that the filiform could not be detached beyond the stricture This danger attaches, of course, to all methods of securing the filiform, but would seem to be especially great in the arrangement exhibited The loss of a filiform in a tight stricture is an extremely uncomfortable accident, in several cases surgeons have even made external urethrotomy to recover it

To Dr Andrews's remark that in case of such an accident urethrotomy is readily avoided by inserting a small lithotrite into the bladder and seizing the filiform, Dr Belfield replied that when there is present a stricture so tight as to require patient work to persuade a filiform to pass, a small lithotrite could hardly enter the bladder unless reinforced by a sledge hammer If the urethra is everywhere large enough to admit a small lithotrite, there could be no danger of losing a filiform because there would be no occasion to use one

Dr Fenn wished to know, if the momentum could be increased by increasing the specific gravity of the fluid, what would be the effect of a greater elevation of the reservoir?

Dr Andrews said that the attachment of a flexible guide to the urethrotome is always a source of care lest it become detached This was less liable to occur with his instrument than in the old way In case it should happen the lost guide could be seized and drawn out with a lithotrite

The question of the pressure of the fluids and the strength of the bladder is one of great interest But little is known about it No more force should be used on a distended bladder, certainly, than a normal one could readily endure We get the measure of this to some extent in the pressure of the expulsive power of the organ, which is a safe limit to keep inside of in the absence of other data The pressure which Bigelow's evacuator ordinarily gives may form another guide, as this is known to be harmless The reservoir must not be placed so high as to cause dangerous distension, should the outflow tube become obstructed In practice forty inches had given all the current needed, and this was doubtless a safe pressure to use in any and all cases

Dr James I Tucker read a paper on

UNDIAGNOSABLE MALADIES

These cases generally are not recorded because there is so little about them that is tangible They are perhaps functional derangements simulating organic diseases, sometimes these cases yielding readily to simple remedies, but are puzzling because so evanescent At other times they are graver, often ending fatally and yielding no facts upon post mortem examination which will aid in a correct diagnosis But the list of undiagnosable ailments is rapidly decreasing, for example, Richard Bright in 1827 explained that dropsical effusions are frequently due to diseases of the kidneys, Thomas Addison in 1855 ascribed to disease of the suprarenal capsule the cause of a form of anæmia accompanied by a dingy discoloration of the skin Until recently zoster frontalis was classified among skin diseases, but now with much accuracy it is traceable to disease of Gasser's ganglion Dr Tucker related a case in which a lady had been twice badly frightened and her nervous system had been severely prostrated At intervals she was attacked with an epileptiform seizure, transient paralysis of the entire left half of the body, constriction of the larynx, a state of trance, and finally a trance like state in which she had died This patient's mother, after a period of nervous disorder, had become a paraplegic, her father was temporarily insane, the eldest brother has an undefinable nervous disorder and a younger brother spasmodic asthma, while a sister has attacks of recurrent chorea major In this peculiar group of nervous disorders what is the underlying cause? It is as yet unknown This case illustrated the difficulty which hedges about the diagnostication of hundreds of cases of disease

Dr Pearson illustrated the difficulties physicians have to overcome in making a diagnosis by reason of the fact that they overlook some points in the history of a case, as in a case in which a patient had swallowed a piece of a metal spoon and it had lodged in the duodenum and blocked up the portal vein

Dr W T Belfield presented specimens of

ANCHYLOSTOMUM DUODENALE

These had been referred to him for verification by Dr R W Gelbach, of Mendota, Ill, who had discovered them in the intestines of young cats that had died of anæmia Dr Belfield confirmed Dr Gelbach's identification of the worms, but for further verification sent them to Dr Joseph Leidy, of Philadelphia, who replied he thought they were anchylostoma, although he had never seen authentic examples Dr Belfield said the anchylostoma are small nematode worms, about half an inch long, which inhabit the duodenums of men and cats, and probably of other animals Discovered in 1838, their pathogenic significance was recognized by Griesinger in 1851, who found in them the cause of Egyptian chlorosis They are veritable leeches which fasten themselves to the intestinal mucous membrane and suck the blood of their host When present in large numbers they induce pernicious and fatal anæmia by exhausting the individual's blood In tropical climates, particularly Egypt and Brazil, cases of pernicious anæmia or chlorosis produced by them are quite frequent, in Brazil such cases are quickly cured by administering the pulp of fresh figs, which destroys the worms Quite recently anchylostoma have been searched for and found in patients dead of pernicious anæmia in Germany So far as Dr Belfield knew, Dr Gelbach is the first to discover the worms in the northern States of the Union Their presence in cats makes it probable that they infest human beings also in this latitude The possibility of this cause of pernicious anæmia should therefore be kept in mind, especially when other recognized causes—chronic nephritis, malaria, etc —cannot be detected

Dr E Andrews asked if these worms were ever found in sufficient numbers to cause death, and he was answered affirmatively

Dr W W Jaggard exhibited the head of a

MEDICAL SOCIETY OF THE DISTRICT OF COLUMBIA

Stated Meeting, April 7, 1886

Vice-President J B Hamilton, M D, in the Chair

Dr J Ford Thompson presented the

SAC OF AN OVARIAN TUMOR

and the following history of the case and operation

Mrs B, age 38, admitted to Garfield Hospital March 9, 1886 First noticed tumor eighteen months ago Four months ago she was tapped in Kansas City and thirty seven pints of fluid withdrawn No trouble followed tapping Her "sickness" had been quite regular all along On admission to the hospital the case book says "General condition excellent, at times suffers severe abdominal pains, skin inactive, tumor nearly as large as before tapping Excellent spirits" Dr Thompson having waited three weeks for the menses, which were overdue, determined to operate, the patient having been properly prepared by baths, mild purgatives, etc

The operation was done on March 11 The incision was made in median line, tumor reached and tapped, thirty six pints of fluid being drawn off The tumor was now found to extend upwards nearly to the diaphragm, and to be closely and generally adherent at that end The incision was continued upwards to umbilicus, the short and thick pedicle drawn out, ligatured, cut and dropped into cavity, while he turned his attention to the adhesions at the other end The incision was again increased upwards, its length being finally about eleven inches Some adherent omentum having been tied and removed, the adhesions suddenly gave way and the sac was removed It was now found that the lower abdomen was full of blood The pedicle was at once drawn out, a second ligatare applied and the stump seared with the thermo cautery All hæmorrhage having ceased, the blood clots were carefully and thoroughly removed There being no oozing from any point that could be seen, the abdomen was sewed up with silver wire except at the lower end, where a drainage-tube was inserted The patient made an excellent recovery from the anæsthetic, without vomiting or nausea There being some pain a morphia suppository, gr $\frac{1}{3}$, was given

March 12 Slept some and rested quietly last night Some nausea this morning Cavity washed out with 2 per cent carbolic acid solution, only small amount of blood serum Temp A M 99 7°, pulse 90, resp 28 P M temp 101°, pulse 108, resp 28 Temp at midnight 100° Milk given during day

March 13 Rested quietly all night Wound dressed as yesterday, looking well, and small quantity of discharge without odor Temp A M 98 8°, pulse 96, resp 20 P M temp 101 3°, pulse 100, resp 20 Suffering from nausea and pain which was relieved by morphia Drainage tube shortened an inch

March 14 Restless all night, nausea, but no vomiting Flatus relieved by rectal tube Wound dressed as before and looking well Temp A M 100 5°, pulse 96, resp 20 P M temp 103°, pulse 118, resp 20 Vomiting frequently during day Champagne given

March 15 Midnight temp 103° Restless and wakeful In the morning nausea and vomiting At 11 A M wound dressed as usual, drainage tube shortened $\frac{1}{8}$ gr calomel every two hours Noon temp 101 8°, pulse 110, resp 20 Enemata of beef tea and brandy every three hours, champagne every hour Consultation 10 45 P M enema rejected and much flatus Temp 101 5°, pulse 124, resp 24

March 16 Slight nausea from champagne Very nervous and sleepless last night Wound dressed Temp 118, pulse 128 Death at 1 25 P M

Autopsy—Abdominal wound healed except where drainage tube Small abscess between two sutures at drainage end and outside the rectus muscle No peritonitis Omentum fresh and no change at points of adhesion Douglas's cul de sac clean On two bunches of intestine which had apparently been in contact with drainage-tube was some plastic material Kidneys not examined

What did she die of? Vomiting began on the afternoon of the third day, although the temperature had been normal in the morning He had talked with her then, and she was in excellent spirits She had passed flatus, so there was no twist of the intestines, although they had been handled considerably in removing clots There was great prostration from vomiting If there was septicæmia it must have been from the stitch hole abscess, which was of unusually rapid formation The thing to be regretted in the operation was the hæmorrhage Such an accident he had never had before, and he thought this time, having made the usual knot (Thomas's), that it was secure He did not, as usual, cut with the cautery, but with scissors, intending to come back to it when he had freed the other end The hæmorrhage was not, however, extreme for a woman of her strength, and was not the cause of the fatal termination Undoubtedly the pedicle, which was very broad, should have been kept in sight

The length of the incision was because of the adhesions He was afraid to use much force, because it was possible that the sac was attached to the gall bladder, liver or stomach, and damage would have been done those organs He therefore continued the incision upwards in order to see Adhesions were very numerous, and a bad prognosis was given He would, however, do such a case, or even a worse case, again, as the probabilities are that it would get well He thought the hæmorrhage was by the cutting of the first ligature The time was fifty-five minutes, most of which was consumed in breaking adhesions and removing clots

Dr E M Schaeffer had examined some suspicious nodules which were found on the inside of the sac He made the following report "The thick portion of cyst wall shows structure of sarcoma or carcinoma, *i e*, large spindle cells in foci and but little fibrous stroma"

Dr J B Hamilton asked the condition of the urine before and kidneys after death

Dr T C Smith asked if it was not possible that in transfixing the pedicle he had punctured an artery What knot was used?

Dr Busey requested Dr Thompson to recapitulate symptoms, beginning at third day after operation

Dr Thompson replied that there had been nothing out of the way with the urine and that the kidneys were not examined at the autopsy He did not think that it made any difference whether an artery was punctured or not, as he used Thomas's knot, which tied everything Beginning at the third day after operation she passed a good night, spirits excellent and temperature normal on morning of third day Pulse 96, resp 20 In the afternoon there was nausea and pain, and the temperature went up to 101 3° Pulse 100, resp 20 On the fourth day she had passed a restless night, nausea, but no vomiting Temp 100 5°, pulse 96, resp 20 Vomiting began this afternoon, the temperature going up to 103°, pulse 118, resp 20 On fifth day the vomiting had continued The midnight temperature was 103° Gave calomel in small doses At noon temperature was 101 8°, pulse 110, resp 20, in afternoon temp 101 5°, pulse 124, resp 24 Much flatus On sixth day, wakeful night At midnight pulse 130 Morning temp 101 8°, pulse 128 Died at 1 25 P M

Dr H D Fry asked if there had been a chill?

Dr Thompson No but there had been a very great change in appearance between the morning of the third day and the sixth day He had never seen such rapid emaciation

Dr Busey Was there any record of the amount of urine?

Dr Thompson None of the exact amount, but the catheter had been used every four hours, and the history simply said plenty of urine passed To a remark by one of the gentlemen Dr Thompson said that he did not attach the same diagnostic importance to the rate of the pulse as to the height of the temperature In reply to a question by Dr Acker he said that antiseptics were used—4 per cent carbolic solution for hands and instruments, iodoform gauze over wound, and over that bichloride of mercury gauze 2 per cent solution of carbolic acid was used for washing out In reply to Dr Smith he said that there was no shock

Dr Smith said that if in transfixing the pedicle an artery be pierced, and if now the pedicle be tied in two halves, the artery is held open and hæmorrhage occurs, the ligature being like two links of a chain

Dr Thompson explained that a third loop was always taken around the entire pedicle

Dr Smith thought that this third loop might be taken *above* the needle hole, in which case it would not stop hæmorrhage

Dr Thompson said that it was usually tied on a level or just below and in any case he did not think hæmorrhage would occur

Dr Smith wanted to know where this hæmorrhage came from Was it the fault of the knot?

Dr Thompson said that every ovariotomist had endeavored to find out a perfectly safe knot, and that it was by no means an easy thing to stop an artery in dense tissue He thought that he had tied this as tight as usual and had used Thomas's knot It is, however, possible that he did not tie tight enough, and he certainly did not cauterize stump as he ought to have done His theory, however, was that the ligature, which was small, had cut into pedicle and hæmorrhage took place from below it

Dr Smith said that it was an important thing to know just where the hæmorrhage does come from, whether from adhesions or pedicle—as a very small hæmorrhage into the peritoneal cavity is a serious thing Adhesions to the bladder were, he believed, the most serious

Dr Hagner said that he had recently seen reported a case very similar to Dr Thompson's The patient had begun vomiting on the third day, and died several days afterwards At the autopsy only a small stitch hole abscess was found out of the way

Dr Busey said that from the autopsy it looked as if septicæmia was the cause of death He did not believe that hæmorrhage or malignancy of the tumor killed the patient here Perhaps if the kidneys had been examined another reason might have been found He thought that the sudden onset of bad symptoms on the third day showed septicæmia

Dr Thompson said he believed himself that it was septicæmia—which was a more or less convenient term when we did not know the real cause It reflects on antiseptic surgery to use this term Nevertheless, it does not upset antisepsis, even when pus is formed, for that may occur in any of the organs of the body unexposed to the air Innocuous pus often occurs in antiseptic surgery, and the surgeon expects it in a certain number of cases

Dr Smith failed to see why Dr Thompson should be surprised at the rapid formation of the abscess

Dr Thompson replied that the time was short for the complete formation of any abscess in previously healthy tissues, but a stitch hole abscess generally takes longer than five days

Dr Busey said that in his previous remarks he had not meant to reflect at all on antiseptic surgery, and he did not believe that it would in all cases save

Dr Hamilton remarked that it was greatly to be regretted that a careful autopsy had not been made, for the whole question turns on what was the cause of death The whole question is now purely one of speculation The operation appears to have been well done, the amount of blood lost at the pedicle trifling, and the theory of septicæmia was open only to the Scotch verdict of "not proven" Was it carcinoma of any other organ? Was it heart clot? He had seen many cases of sudden death from heart clot on the fifth or sixth day after capital operations Was it a sudden failure of the heart? Was it concealed hæmorrhage? All the organs not having been examined, it certainly was impossible to arrive at the cause of death

Dr Toner said that he thought Dr Thompson had not made the difficulties of the operation as prominent as they ought to have been He had been present at the operation and had seen the quantity and solidity of the adhesions, which to him, who was not very familiar with abdominal surgery, seemed appalling

Dr A F A King read a paper on

THE CONSERVATIVE ELEMENT IN DISEASE,

in which, after recalling the titles of his various papers, previously published, on this subject, he proceeded to explain that the element of conservatism must be sought for only in those pathological phenomena that are regulated by *vital* laws, and not in others, such as calculi, emboli, etc , which are either accidental products or formations, determined by *physical* or *chemical* laws, outside the pale of nervous control Neither could any conservative design be discovered, or expected, in many of the pathological phenomena observed after dissolution, because they were *final phenomena*, produced after the body began to die

He next proceeded to explain that the vital phenomena of pathology were *acts* performed by the organism, under the control of the central nervous system, and for the benefit and preservation of that system, by which, indeed, the entire body was owned and governed, and the cessation of whose functions was immediate death Under all circumstances, therefore, if life was to be maintained, the functions of the nervous system must be preserved, pleasantly and by physiological processes if they *can*, painfully and by pathological processes if they *must* Hence many vital processes which *appear* to kill, may all the time have postponed the fatal event, by contributing to maintain the functions and nutrition of the great nerve centres

His conclusions were that in studying the *vital* phenomena of pathology, with a view to understand their natural purposes and conservative design, we must bear in mind *First* That these processes are *acts executed by the body* *Second* That these acts are *authorized*, *regulated*, and *controlled*, by the *central nervous system*, which *owns* the organism, and constitutes the coordinating power by which the whole body is governed, and its forces distributed *Third* That this government is, in every particular, *limited* —limited in *material*, limited in *force*, and limited as to *duration*, and hence, for evident reasons, its conservative designs may fail, and death follow *Fourth* Unless the vital processes of pathology are studied in relation with these fundamental facts, it will be impossible for us to say, with anything like judicial accuracy, what processes are right or wrong, and what destructive or conservative

Dr King further remarked that he had begun with the view of explaining "The Conservative Function of Fever," but that the premises which he had laid down had led him off He said he believed that fever was a conservative process set up by the nervous system in antagonism to some pathological process, and on the whole was not killing but helping to save the patient He said that he had not fully explained this or the above, but as he had already consumed so much time he would stop,

OBSTETRICAL SOCIETY OF PHILADELPHIA

Special Meeting, April 15, 1886

THE PRESIDENT, B F BAER, M D, IN THE CHAIR

W H H GITHENS, SECRETARY

DR M PRICE reported two cases of

EMMET'S BUTTON-HOLE OPERATION

I desire to call the attention of the Society to a novel operation for the diagnosis and treatment of urethral and vesical diseases and accidents incident to parturition, devised and practised by Dr Emmet, of New York, for the past six years In the last edition of his work on gynecology he treats the subject elaborately, and gives it, as in his judgment, the most rational treatment for prolapsus of the mucous and submucous tissues urethrocele, lacerations of the urethra from dilatation or injuries in labor, gonorrhœal inflammation, and abscess in the urethral wall

I desire to report two cases of this operation, in which no other treatment, in my judgment, would have been of the slightest benefit to the patients The operation recommended by Dr Emmet is what he designates as his "button hole operation of the urethra," and may be performed either in the Sims's position or in the lithotomy position The operation consists in opening the urethra from three-fourths to one inch, midway between the urethral orifice and the neck of the bladder, thus giving ample room for inspection of the canal for any growth or condition that may require drainage or operative procedure In those cases where the opening is made for diagnostic purposes simply, the opening may be closed with sutures, or be allowed to close in its own way Many cases of urethral irritation are wonderfully benefited and most of them entirely cured simply by the free drainage it allows The mucous membrane of the urethra and vagina are tacked together in these cases to prevent retraction In the operation for urethrocele, the urethral opening is made through the pouch or dilated portion of the urethra, while a block tin bougie is held in the bladder The opening is continued down into the mucous membrane covering the sound, and a sufficiently large piece of the mucous membrane of the vagina removed to insure the removal of the pouch The mucous membrane is then taken under the sound and drawn through the button-hole opening, so as to obliterate the redundancy of mucous membrane Sutures are then passed from the vaginal surface to the block tin sound and back on the opposite side in the same position, all the sutures being thus introduced before cutting away the redundant mucous membrane held by a tenaculum in the hands of an assistant This is to prevent the possibility of failing to incorporate the mucous membrane of the urethra in the sutures and so fail to secure a perfect result, inasmuch as it is the mucous membrane which, on account of its diseased condition, is giving the most trouble This is also the operation performed for prolapse of the mucous membrane, its redundancy being pulled through the button hole opening, back from the meatus, and there fastened The redundancy is then cut away, instead of cauterizing it, as in the past

The first case is that of a lady 32 years of age, the mother of four children The last labor was very brief, as the woman was delivered with forceps in the hands of a medical man, who had another engagement and could not be delayed This was four years ago The woman, when she came into my hands, was suffering from a double laceration of the cervix, which was torn back to the vaginal vault, with laceration of the perineum back to the sphyncter, and with a urethrocele that would have held two drachms of urine There was also quite a protrusion of the mucous membrane of the urethra, what Emmet calls "hæmorrhoids of the urethra," from constant straining to pass urine This woman had suffered constant tenesmus or bearing down pains ever since her confinement, with inability at times to go more than half an hour without passing urine, at other times she was compelled to micturate every few moments, the urine passing with the greatest difficulty This was making great inroads upon her health She had consulted quite a number of physicians and was treated, from what I can understand, for "cystitis" and "ulceration of the womb" This, I believe, was the diagnosis of her trouble by the gentleman who had rendered her such efficient service at her delivery The patient was operated on after the method of Dr Emmet An opening one and one-fourth inches in length on the vaginal surface and three-fourths of an inch in the urethral wall was made and the superfluous mucous membrane, both from the urethrocele and from the mouth of the urethra, drawn through the vaginal aperture, and the sutures put in before cutting away the redundancy of tissue Seven sutures were applied, and a perfect result was obtained in one week When the sutures were removed they were all found in a space not larger than the end of my thumb, in consequence of the contraction of the tissues The woman passed her water ten hours after the operation, and continued to do so afterward without pain or discomfort At the present time, three months after the operation, she says she is better than she has been at any other time since her last labor I would also state that the perineum and cervix were repaired at the same time Silk-worm gut sutures were used in this case

The second case is one of great interest from a medico-legal point of view, as the cavity of the urethrocele was lined with a pus secreting membrane The patient, although under my care, was not examined until after the urethrocele became very troublesome I then learned that difficulty from this source, gradually growing worse had been experienced for four years These facts were not ascertained until the husband had repeatedly presented himself for treatment of a mild urethritis which always developed after sexual intercourse His condition had been attributed to other than legitimate causes After a considerable number of attacks, he began to inquire the cause of his affliction Having been asked the question as to "foreign relations," he stoutly denied any such cause, though he admitted that he had suffered from gonorrhœa early in life, but had been completely cured long before the time of his marriage, some fifteen years ago He was then asked to have his wife present herself for examination at my office I found her suffering from laceration of the cervix and a urethrocele The urethrocele was exceedingly tender to pressure and had the feel of a fibrous growth, no fluctuation could be detected upon light handling in examination A pus cavity was suspected, from the painful character of the tumor and the husband's condition Repeated attacks of urethritis following sexual intercourse indicated an unusually irritating discharge from some source, and as the mucous surface of the vagina and cervix was in a healthy condition, and the discharges mild and unirritating, there could be but one rational explanation of the husband's condition, viz a suppurating sacculated condition of the urethrocele, with periodical discharges of pus Examination under ether fully confirmed the suspected pathological condition The urethrocele was thickened, corrugated, and filled with purulent ammoniacal urine The patient was placed in Sims's position, and the operation was performed as detailed in the other case, except that the pus-secreting membrane was carefully removed with the scissors, and the edges of the healthy mucous membrane were picked up with a tenaculum and the sutures of silk-worm gut introduced as in the case before cited A perfect result was obtained, removing all irritation of body and mind

Dr Joseph Price reported for Dr Barton Hirst, a case of

VULVO-RECTAL FISTULA FROM VIOLENCE DURING FIRST COITION

The patient, a young woman of 22 years, presented herself at the gynecological clinic of the Philadelphia Dispensary, with the following history Previous to her marriage, which took place eighteen months ago, she had been a perfectly healthy woman From the first attempt at sexual intercourse with her husband, which caused her to suffer such acute pain that she almost fainted, she dates all her trouble The sexual act was also followed by severe hæmorrhage, which persisted for a month, the passage of fæces and flatus *per vulvam* was at once noticed Every repetition of the sexual act for the next two or three weeks was followed by renewed bleeding, and even at the present time she suffers severely during intercourse The passage of the fæcal matter through the vulva gradually increased in degree until the rectum was evacuated entirely through the vulva There has been entire inability to retain flatus and fæces Examination The finger on entering the vulva passes at once into the rectum through a patulous opening of sufficient size to admit two fingers Inspection shows a perfectly intact crescentic hymen of moderate thickness and rigidity, having a small anterior opening Immediately in front of its posterior attachment is an irregular transverse tear, an inch and a half in its longest diameter, with thickened and everted edges, extending backwards and upwards for about one and one half inches, exposing to view the mucous membrane of the bowel The vagina is small and has evidently never been entered The operation proposed by Dr Joseph Price, and done by him March 16, 1886, consisted in freshening the edges of the tear, partially loosening the hymen from its attachment and using it as a flap to supply the deficiency Spotted silk worm gut sutures were used, and the closure, after the operation, was complete and resulted in perfect union This form of injury to the vulva is very rare, for although sixteen cases[1] of rupture of the vagina have been reported during late years as occurring during coition, only one of them, recorded by Blumenthal and operated on by Sir Spencer Wells at the Samaritan Hospital, in 1860, bears any resemblance to the present case, which, from the careful analysis given it by Dr Harris, is without doubt one of vulva-rectal fistula This form of fistula is much less common than the recto-vaginal The case here reported is of especial interest from the fact that the traumatism undoubtedly occurred during first coition, from the virginal condition of the hymen and from the long time during which sexual relations were maintained under circumstances which must have been disagreeable to both husband and wife There was no sign or suspicion of specific taint in either man or wife

---

[1] Paul F Mundé two cases Boston Med and Surg Jour 1885
Treiss, two cases Centralbl f Gynækologie 1885
Chadwick, one case Boston Med and Surg Journal
Colles, one case London Med Times and Gazette

Dr R P Harris remarked that he had seen and examined the patient, and was struck with her emaciation He inquired of her sister if she had not lost a great deal of flesh since her marriage This brought out three photographs, all of which represented a short woman of full habit, one of them having been taken two months before her marriage The sister stated that the patient had no control over her evacuations from the rectum, and that she was being constantly soiled by their escape But for the fact that the husband had been deprived of his prepuce in infancy, thereby rendering the penis callous by the exposure of the glans to the air, it is hardly possible that he could have forced the organ through the flesh as he did, without so much personal suffering as to compel him to desist Possibly also the tissues penetrated may have been less resisting than normal As the arm of a fœtus has been known to perforate the rectum and protrude at the anus during labor, without laceration of the perineum, there must be in some women a much less than usual strength in the rectal wall In considering the emaciation of this woman during the eighteen months of her married life, the question naturally arises, was this condition due to the want of rectal alimentation, to the constant loss of fæcal matter, or to the depressing effects of her condition, weakening her appetite and rendering her life miserable? The opening through the fossa navicularis into the rectum corresponded exactly with some of the cases of congenital malformation which Dr Harris had met with, and particularly with one in a large stout primapara In her, however, there was a slight anal sphyncter, and except when affected with diarrhœa she had control over her evacuations The only case upon record which corresponds to this was operated upon by Sir Spencer Wells, in December, 1859, at the Samaritan Hospital

Dr Price remarked that eighteen gut sutures were introduced in closing the wound

Dr Charles Meigs Wilson exhibited a

FIBROID POLYPUS OF THE UTERUS

This specimen was removed three weeks ago from the uterus of a patient with the following history For the past three years she had been flooding almost constantly Her flow had increased regularly at her catamenial periods, and at no time had it entirely ceased See had suffered all that time agonizing pain, greatly increased during the menstrual period The continued loss of blood had reduced her weight one fourth, and the continued anæmia of her nerve centres had produced characteristic effects During all this time she had had given her all the agents of the pharmacopœia vaunted for their efficacy in controlling uterine hæmorrhage But the cavity of the uterus had never been explored, save in a desultory way with a sound When first seen she was extremely anæmic, emaciated, troubled with insomnia, and had a very irritable stomach The uterus was dilated with the Ellwood Wilson curved dilator The growth, then readily seen, was grasped with a volsellum and dragged as far as possible from the uterus, a curved crescentic shaped, probe-pointed bistoury was then made to sweep over the surface of the growth until it came in contact with the sessile attachment of the tumor, which was severed with a sawing movement of the knife Prior to the operation large doses of the fluid extract of ergot were given to the patient for forty eight hours, in order to insure powerful contraction of the uterus after the tumor was removed Immediately after the ablation of the growth, the cavity of the uterus was smeared with a solution of one part of Tait's iodine and two parts of pure carbolic acid During the operation the patient lost half an ounce of blood The removal of the tumor would undoubtedly been accompanied by excessive hæmorrhage had not the precaution have been taken to secure prompt uterine contraction by the previous administration of ergot The patient made a happy recovery, has lost no blood at all since the operation, has gained in weight and improved in appetite The case carries with it its own lessons All the fruitless medication and the long period of suffering and distress might have been avoided had her medical attendants, at the beginning, dilated and explored the uterine cavity, removing the cause of the hæmorrhage instead of temporizing and making use of methods which at best, in cases of continued hæmorrhage from the cavity of the uterus, are of a prophylactic nature The polypus when fresh was four inches in length, two and a quarter in breadth, and one and three-quarters in thickness

Dr Goodell thought it was an error to expect hæmorrhage after the removal of uterine fibroids Velpeau had removed a very large number of these tumors, and his method had been to cut them away by means of a knife, and yet he had hæmorrhage in two cases only Dr Goodell has removed very many of these tumors, and has employed every method, he has never had any trouble from hæmorrhage In Constantinople, while young in experience, and in consultation with another very young man, he saw a case in which auto-enucleation had commenced The tumor was too large for removal by means of the écraseur, as the vagina was so filled up that the wire could not be got up to the base of the tumor They concluded to cut off all they could

get at, and then gave ergot The next day another large slice was removed, and at the end of a week they succeeded in dividing the false pedicle and all was safely removed, without any hæmorrhage whatever Since then he has ceased to fear hæmorrhage, and thinks a danger is incurred by the use of ergot in causing contraction of the cervix uteri and incarcerating the tumor He removes many submucous tumors by dilating the cervix with his dilator, passing in the polypus forceps and accomplishing the diagnosis and removal at the same time, the latter being effected by twisting When he has recourse to the écraseur, he now uses the finest piano wire, which is more efficient than the heavier and less liable to break He first pushes the écraseur up to the fundus uteri with the wire bent over, and then coaxes the wire up, and in this way has little trouble in getting it around the base of the tumor Before tightening the wire he removes traction from the tumor and pushes up with the écraseur, so as to correct any inversion of the uterus that may have been caused in pulling the tumor down Now when the wire is tightened the tumor will be divided without fear of injury to the uterine tissue

Dr Howard A Kelly said the choice of method in these cases should depend largely upon the individual peculiarity Chassaignac's ecraseur had rendered him good service in those polypi having broader bases of attachment, but when this is at the fundus and a large tumor chokes the vagina or cervix uteri, the difficulty of satisfactorily fixing the loop is very great The porte-chaine added to the écraseur by Marion Sims is serviceable, but nothing will compare with the flexible, easily adjusted wire of a Braxton-Hicks écraseur Where the pedicle was neither large nor dense he has had great satisfaction in the use of phosphor bronze wire, which is so much more easily manipulated than piano wire Scanzoni's plan of cutting the tumor off when the pedicle is long is excellent and safe It goes without saying now that rigid antiseptic precautions should accompany any such operation

Dr Parish did not think there was much difference in the method of different operators He never gives ergot before any intra-uterine operation in which he wishes relaxation of the cervix With the ecraseur he uses wire and introduces it in the manner described by Dr Goodell, and uses jeweler's pliers to manipulate the wire, pushing it up and around the tumor He has no fears of sepsis if all the tumor be removed, but he takes the precaution of injecting a very hot solution of mercuric chloride after operating

Dr Montgomery has had free hæmorrhage after removing uterine fibroids by means of the écraseur This hæmorrhage was so free in one case that hot water injections would not control it, and Mensel solution was applied with success He, however, would not give ergot beforehand for fear of causing rigidity of the cervical tissues In one instance large piano wire snapped several times on account of the firm, dense character of the pedicle, and he had recourse to cutting away portions of the tumor, the remainder being thrown off by natural action The tumor had been adherent to the posterior wall of the uterus and had been partially enucleated before operation The patient was very weak, and septicæmia and death resulted In a case in which he used the wire écraseur a portion of the tumor was left, it was thrown off by auto enucleation, and was very offensive The patient did not suffer from sepsis, but having wounded his own finger with a tenaculum in its removal, he was very sick in consequence He thinks the spoon curette or saw would be the best instrument in the enucleation of large fibroids

Dr Goodell carefully cleanses out the vagina before and after operation He formerly used carbolic acid, but now prefers the mercuric chloride He prefers the high note piano wire, which has never broken in his hands, as it cuts as well as crushes

Dr W S Stewart is glad to hear about the greater strength of the small piano wire, as he has been using triple twisted wire and has been much troubled by its breaking, so that he has given it up for the chain He had mentioned his trouble to Gemrig, who recommended iron wire, which has been answering a very good purpose He much prefers Labarraque's solution of chlorinated soda as an antiseptic and disinfectant

Dr Goodell remarked that the finer piano wire was not stronger, but was more efficient, as it cuts more easily through the tissues Twisted wire will break more easily than single because the strain on the different strands is unequal

Dr Baer agrees with Drs Goodell and Parish as to the unadvisability of using ergot before operating He has given up the écraseur on account of the difficulty attending the breaking of the wire He is now in the habit of pulling down the tumor and removing it piecemeal He uses vinegar if a styptic is needed

Dr Wilson has seen one death follow the use of the écraseur, and has had trouble in adjusting the wire, the liability of removing uterine tissue by the wire is a great danger He thinks it better to drag the tumor down and cut it off in pieces He feared hæmorrhage in this patient on account of the fearful loss of blood which she had already sustained He considered prophylaxis the safer course

VAGINAL HYSTERECTOMY

Dr Wm Goodell exhibited a womb which he had removed per vaginam The woman had been brought to him by Dr F R Gerhard, of Douglassville, Pa She was 65 years old and had given birth to twelve children She had a hypertrophic elongation of the womb, the sound giving a measurement of minus five inches Her cervix was outside of her body, and it was very greatly enlarged in every direction by a carcinoma On March 10, before the students of the University of Pennsylvania, he amputated the cervix after applying an elastic ligature, but finding that Douglas's pouch had been opened, he concluded to perform the radical operation The womb was accordingly retroverted, its attachments to the bladder severed, the broad ligaments tied *en masse*, each with two strong ligatures, and the womb removed The large gaping wound was closed by seven wire sutures, leaving only a small opening through which the ligatures passed and acted as drainage tubes

Sublimated cotton was lightly packed into the vagina This was removed twice a day and the womb syringed out with a 1–2000 solution of mercuric chloride On the next day the temperature rose to 100 2°, but it never after that day reached 100°. The sutures were removed on the fourteenth day, and with some difficulty, as they were now high up in the apex of a cone-shaped vagina She was able to go home on the twenty third day after the operation

Dr H A Kelly remarked that he wished in this connection to emphasize a point of vital importance in every operation where there is either artificial or pathological descent of the cervix proper The slightest traction, elongating the cervix, draws the vaginal vault down over the displaced supra-vaginal portion, like the finger of a glove, and unless especial care is directed to this point, there is imminent danger of scalping the vagina in any operation then performed on the cervix In lacerated cervix, particularly where Dawson's scissors are used (and great downward traction is fashionable), and the bases of the broad ligaments are opened in this way, and in amputation intended to be limited to the infravaginal cervix, as in this case of Dr Goodell's, either the scalping process lays bare a broad tract of areolar tissue in the vault around the cervix, or, worst of all, Douglas's pouch is laid open It is unnecessary to enlarge upon the greatly increased dangers of septic infection He would ask Dr Goodell in relation to the after treatment of this case In the latest contribution to this subject by Dr Brennecke, of Magdeburg, in the *Zeitschrift fur Geburtshulfr und Gynecologie*, he clearly shows that those cases ran a most favorable course in which the iodoform tampon was not removed for six or seven days, and that syringing after operation with a view of carrying off foul dis charges is a pernicious practice, as it separates the peritoneal surfaces which have just formed delicate adhesions, and breaks up the early steps of repair without the possibility of accomplishing its purpose A point well worthy attention is Brennecke's method of dealing with the upper part of the stump of the broad ligaments, which are caught in stout ligatures Experience has shown that the distal end is very apt to slough, and to secure an indemnity from the dangers of sloughing, Brennecke ties the ligatures of opposite sides across and everts the two stumps thus fastened together, into the vagina, where they cannot do harm, and help form a plug for the wound

Dr Montgomery questions the propriety of total extirpation of the uterus How long is the patient likely to live after this operation? If partial removal gives equal relief from the disease for which the operation is performed and an equal or greater chance for a prolongation of life, it is to be preferred as the least dangerous Hoffmeier in a summary of German gynecological work opposes total extirpation if it can be avoided He reports 145 cases of partial and thirty nine of total removal of the uterus Ten of each series were fatal In six of the partial cases the result was unknown Of the total removals six only were living at the end of two years and none at the end of three years, while of the partial six still lived at the end of the fifth year Following the plan suggested by Sims and Van de Warker in cases of malignant disease of the cervix, Dr Montgomery makes an incision into the uterus at the vaginal junction and dissects upward as closely as possible to the peritoneal surface while making traction on the cervix, thus, as it were, enucleates the uterus, leaving a very thin wall, he then stuffs this cavity with a mixture of equal quantities of zinc chloride and water on cotton tampons to cause a slough of any diseased tissue that may have been left behind If by chance the sloughing should perforate the peritoneum, the previous inflammatory exudation would save the peritoneal cavity from invasion

Dr H A Kelly does not wish the claim of an eminent American surgeon to priority in this matter to be forgotten The credit of originating the highest practicable one shaped amputation of the uterus, and establishing its great utility, its safety and relatively greater success is due to Dr Baker, of Boston, He uses no cautery and controls hæmorrhage perfectly by the effect of the strong downward traction upon the vessels

Dr Parish mentioned an earlier operation by Hirth, of San Antonio, Texas, who practiced the method described by Dr Montgomery, of enucleating the uterus from its peritoneal covering He divided the vaginal mucous membrane and gradually shelled or scooped out the uterine tissue The operation was accompanied by great hæmorrhage

Dr C M Wilson, thought such an operation very dangerous and liable to be followed by secondary hæmorrhage He has in two cases after Dr Baker's method, used a hot tamponade of the uterus and vagina after the operation Dr M McCormick, of London, packed the stump with bandage or gauze, filled with iodoform, and allowed it to remain undisturbed for nine days This was perfectly sweet when removed, and is a good and safe plan of after treatment

Dr Goodell said that the method of Brennecke's, of not washing, seemed to him to be undoubtedly a good one, and he would in future adopt it He once had an alarming hæmorrhage from the division of a large vessel after a hole had been accidently made in Douglas's cul de sac in the high amputation Consequently he could not pack the vagina for fear of forcing blood, etc , into the peritoneal cavity, and he had to control the bleeding by twisting a wire around it He generally uses Paquelin to control hæmorrhage in these cases, and has operated upon at least 200 with only four deaths Neither of the fatal cases were high operations One death was from secondary hæmorrhage, one from tetanus, one from a frank peritonitis and one from septicemia He thinks the high operation the most feasible one in the majority of cases in which the womb is movable and he has extirpated the womb but twice for carcinoma

Dr H A Kelly exhibited the sac of an

OVARIAN TUMOR THAT WEIGHED AT REMOVAL ONE HUNDRED POUNDS

Dr Goodell congratulated Dr Kelly upon his success in removing such a large tumor He, Dr Goodell, had on one occasion removed a tumor weighing 112 pounds from a woman, who after the operation weighed only 74 pounds As in Dr Kelly's patient the tumor reached the patient's knees and she could not lie down After the operation the large folds of the stretched skin were a great annoyance, but after some months it had entirely contracted The patient made a complete recovery

Dr M Price had been present at Dr Kelly's operation A large vein was torn and a stream of blood as large as his finger poured out The patient collapsed instantly and Dr Price thought her dead, but he was surprised and pleased at the effects of a hypodermatic injection of ʒj of sulphuric ether which restored the pulsation quickly

DOMESTIC CORRESPONDENCE

THE DANGERS OF KISSING

To the Editor of the Journal

Dear Sir —Apropos to the paper of Dr Samuel S Adams, in your issue of May 22, allow me to thank him for the paper and to report two cases of syphilis from kissing

About 1872 a young man presented himself at my office with a full blown chancre on his penis, and syphilitic sore mouth He was treated *secundam artem* and went his way Some weeks later I received a letter from him saying that his chancre was healed and that he was doing well, but that he was in further trouble—that a few days after consulting me he had kissed a young lady at an evening party in Altoona, and that she had syphilitic sore mouth as a result

Recently I was consulted by a young married woman She was a stout, robust person, of great natural physical strength She presented a squamous eruption, syphilitic sore mouth and condylomata I sent for her husband He was perfectly healthy, vowed, and I believe truthfully, that he was and had been pure I told him the condition of his wife, and warned him against infection We then began an investigation of the origin of the wife's infection And it may be well to state here that I had not questioned her chastity I knew the woman The search was attended by success A brother had long been absent, returned home with syphilis, kissed his sister and infected her He remained at home for some time, and during the time was treated for his malady by a physician within three minutes' walk of my office

If these cases will help the cause I will be rejoiced

R Stansbury Sutton

BOOK REVIEWS

The Lettsomian Lectures Delivered at the Medical Society of London, 1872, on The Pathology and Treatment of Some Diseases of the Liver By S O Habershon, M D Lond, F R C P, Late Senior Physician to, and Lecturer on Medicine at, Guy's Hospital, etc Second Edition 8vo, pp viii, 111 Philadelphia P Blakiston, Son & Co Chicago W T Keener

It is to be regretted that Dr Habershon should have sent out a second edition of these lectures without making radical changes in the form and subject-matter It is equally to be regretted that he should have chosen such a large subject for three lectures, and so small a book It is not to be compared in any way with his Lumleian Lectures on the "Pneumogastric Nerve," delivered in 1876 What there is of therapeutics in the book cannot be highly commended, the pathology, which one would expect from the title, amounts to almost nothing, and the physiology is not up to date There is no index to the book

Lectures on the Diseases of the Nose and Throat Delivered during the Spring Session of Jefferson Medical College By Charles E Sajous, M D, Lecturer on Rhinology and Laryngology in the Spring Course of Jefferson Medical College, One of the physicians in charge of the Throat Department, Jefferson College Hospital Fellow of the American Laryngological Association, Corresponding Member of the Royal Society of Belgium, and of the Medical Society of Warsaw (Poland), etc, etc Illustrated with One Hundred Chromo Lithographs, from Oil Paintings by the Author, and ninety-three Engravings on Wood 8vo, pp xii, 439 Philadelphia F A Davis, Att'y, Publisher, 1885

Medical literature of recent date is so profuse, so verbose, and so frequently is one book but a paraphrase of another, that we are gratified and much refreshed by the originality of Sajous' Lectures on the Diseases of the Nose and Throat Like a certain work of which it was facetiously written—"The good things are not new and the new things are not good" —*this book* "contains both good things and new things, but unlike the first mentioned, the new things *are* good and many of the good things are new Ninety seven of the one hundred chromo lithographs are original, nearly all of the instruments and apparatus depicted are the author's own or the author's modification, and his modifications are not of the useless variety, but they invariably impress one as precisely the improvement needed to remedy a genuine defect Indeed, we cannot but admire the keenness of conception and wealth of device displayed in the many ingenious and withal simple inventions necessary to meet the indications

As the difference between the normal and pathological state is often appreciable only in the change of color, this value for illustration of the numerous chromo lithographs is at once apparent In preparing them Dr Sajous, again uniquely original, has performed the part of artist as well as of anatomist, and so successfully that we turn from one plate to another with ever increasing delight

Prescriptions which comprise a number of remedies, have specified in smaller type, opposite each ingredient, the particular purpose for which that agent is employed Knowledge of an exact character, of which we are much in need in connection with local applications to mucous surfaces, is thus imparted

Only the best therapeutic measures are recommended, faulty ones are denounced, and others are omitted Useless discussions and doubtful theories are excluded and their space devoted to details of a practical nature Instance, the section on hypertrophic rhinitis or hypertrophic nasal catarrh, wherein the various operative procedures and the requisite apparatus for the effective treatment of suitable cases by the galvano cautery, are described with exemplary minuteness and in a singularly lucid and interesting manner

The phraseology, throughout, is plain and concise, the paper and print are good, and typographical errors are few in number

We regret that it was found expedient to publish the work only by subscription, and hope that another edition will soon be issued to the trade so that it may be within the reach of all

NECROLOGY

WILLIAM OWEN BALDWIN M D

William Owen Baldwin, M D , of Montgomery, Alabama, died at his residence in that city on Sunday, May 30, 1886 He was born in Montgomery County on August 9, 1818 Dr Baldwin was the son of William and Celia (Fitzpatrick) Baldwin His mother was the sister of U S Senator Benjamin Fitzpatrick, formerly Governor of the State of Alabama After receiving a good collegiate education he studied medicine in the office of Dr McLeod, of Montgomery He attended medical lectures at the Transylvania University, Lexington, Ky , and received his degree of M D in 1837 He began practice in Montgomery and was associated with Dr Wm M Boling, which association continued until 1848 In the meantime he visited Europe, and spent a year there in study in the leading medical schools and hospitals

He was ambitious and well prepared in his profession, and justly took high rank among the foremost practitioners in his section of the country, and he was an interested student up to the time of his death In debate he was a ready and eloquent speaker, and was an elegant and fluent writer The medical journals contained numerous and valuable articles from his pen, from the time of his graduation to within the past year His graceful tribute to the memory of his old and esteemed friend, Dr J Marion Sims, will be remembered by most physicians of the present day But he also wrote well on many of the more important diseases and questions of interest to the profession of the South He was an original member of the Medical Association of Alabama, has served as its President, and was a valued contributor to its *Transactions* He was also an active member of the Medical and Surgical Society of Montgomery County, and was honored with its highest offices He was a member of the American Medical Association in 1868 and its President in 1869, presiding at the meeting in New Orleans in that year His address as President on that occasion is replete with Christian and patriotic sentiments, so beautifully expressed and well timed as to remain shining landmarks in the history of the Association The committee charged with organizing the Ninth International Medical Congress, which is to assemble in Washington City in 1887, had chosen Dr Baldwin as one of its Vice-Presidents, his success in the profession and his high character as a man fully warranting the selection In social life he was by nature a leader, his culture and refined feelings of a high order gave him real, not accidental prominence Well versed on almost every topic, with a deferential manner and an agreeable voice, he was the chosen and welcome oracle of every circle

Dr Baldwin had been in poor health for several years, but his friends at a distance hoped his life would be spared for further usefulness He leaves a wife and several sons and daughters We hope to give at some time a more complete sketch of the life of Dr Baldwin

MISCELLANEOUS

The New Hampshire State Medical Society will hold its sixty ninth annual meeting in Concord, on June 15 and 16

Reduced railway rates are as follows The Concord will sell tickets to members and delegates to Concord and return at two cents a mile each way, from Manchester, Nashua Junction, Portsmouth Newmarket Junction, Epping, Raymond, Candia, Salem, Derry, Londonderry, Lawrence, Hooksett, Suncook, Pittsfield and Goffstown The Northern and White Mountains Divisions of the Boston & Lowell will sell tickets to Concord and return at two cents *per mile*, each way, from White River Junction, Lebanon, Enfield, Canaan, Grafton, Potter Place, East Andover, Bristol, Franklin, Boscawen, Penacook, Claremont, Newport, Bradford, Warner, Peterborough, Hancock Junction, Antrim, Hillsborough, Henniker, Contoocook, Groveton Junction, Lancaster, Whitefield, Fabyan's, Littleton Lisbon, Woodsville, Haverhill, Warren, Rumney, Wentworth, Plymouth, Campton, Ashland, Meredith, Weirs, Lake Village, Laconia and Tilton The Boston & Lowell R R will sell tickets from Keen and Marlboro' to *Hancock Junction and return*, and from Wilton, Milford and Amherst to *Concord and return*, for two cents per mile, each way

To secure Reduced Rates, tickets must be bought at these Stations

This arrangement is for June 14 to 17 inclusive Members can take advantage of it to attend the meeting of the Council, Monday evening, and also to remain and attend the meeting of the Alumni of Dartmouth College, which will be held in Concord City, June 17

The Chicago Policlinic —This school, which has now been fully organized, will begin its courses of instruction on July 6 The systematic and regular courses of instruction will be held in the Hospital and weighed only 74 pounds As in Dr Kelly's patient the tumor reached the patient's knees and she could not lie down After the operation the large folds of the stretched skin were a great annoyance, but after some months it had entirely contracted The patient made a complete recovery

Dr M Price had been present at Dr Kelly's operation A large vein was torn and a stream of blood as large as his finger poured out The patient collapsed instantly and Dr Price thought her dead, but he was surprised and pleased at the effects of a hypodermatic injection of ʒj of sulphuric ether which restored the pulsation quickly

MISCELLANEOUS

The New Hampshire State Medical Society will hold its sixty ninth annual meeting in Concord, on June 15 and 16

Reduced railway rates are as follows The Concord will sell tickets to members and delegates to Concord and return at two cents a mile, each way, from Manchester, Nashua Junction, Portsmouth Newmarket Junction, Epping, Raymond, Candia, Salem, Derry, Londonderry, Lawrence, Hooksett, Suncook, Pittsfield and Goffstown The Northern and White Mountains Divisions of the Boston & Lowell will sell tickets to Concord and return at two cents per mile, each way, from White River Junction, Lebanon, Enfield, Canaan, Grafton, Potter Place, East Andover, Bristol, Franklin, Boscawen, Penacook, Claremont, Newport, Bradford, Warner, Peterborough, Hancock Junction, Antrim, Hillsborough, Henniker, Contoocook, Groveton Junction, Lancaster, Whitefield, Fabyan's, Littleton Lisbon, Woodsville, Haverhill, Warren, Rumney, Wentworth, Plymouth, Campton, Ashland, Meredith, Weirs, Lake Village, Laconia and Tilton The Boston & Lowell R R will sell tickets from Keen and Marlboro' to *Hancock Junction and return*, and from Wilton, Milford and Amherst to *Concord and return*, for two cents per mile, each way

To secure Reduced Rates, tickets must be bought at these Stations

This arrangement is for June 14 to 17 inclusive Members can take advantage of it to attend the meeting of the Council, Monday evening, and also to remain and attend the meeting of the Alumni of Dartmouth College, which will be held in Concord City, June 17

The Chicago Policlinic —This school, which has now been fully organized, will begin its courses of instruction on July 6 The systematic and regular courses of instruction will be held in the Hospital and

Dispensary building, at the corner of Chicago and La Salle avenues The courses will be of six weeks' duration Dr Wm T Belfield, 612 Opera House Block, is the Secretary

The Michigan State Medical Society will hold its twenty first annual Session in Jackson, beginning on Wednesday, June 9

New York State Medical Association, Third District Branch will hold its second annual meeting in the Court House in Binghamton on June 17 The programme includes nineteen papers

Prof Hans Gierke —The University of Breslau has lost one of the most popular of its medical staff in Dr Gierke, who died on the 8th inst in the Maison de Santé at Schoneberg, near Berlin Hans Paul Bernhard Gierke, brother of the well known Professor of Law in the University of Heidelberg, was born on the 19th of August, 1847, at Stettin After completing his academic studies he came before the public with his first scientific work, "Ueber das Athmungscentrum" ("on the Respiratory Centre") At the instance of Dr Kolliker, he went in 1876 to Tokio to fill the Chair of Anatomy in the Imperial University of the Japanese capital By that time, however, the seeds of a lingering malady had declared themselves, and in 1881 he returned home to assist Professor Heidenhain in the Physiological Institute at Breslau, where he was appointed in the following year Extraordinary Professor Advancing illness compelled him to seek a more southern climate, but the change brought him no benefit Before his death his valuable collection of Japanese objects was exhibited in the Industrial Art Museum of Berlin, while his rich assortment of Japanese pictures was purchased by the State for the Ethnographic Museum of the same city —*Lancet*, May 22, 1886

Vaccination in Japan —The Japanese do not appear to have lost any of their faith in the efficacy of vaccination for the small pox They have just enacted a very stringent law on the subject, for besides ordinary vaccination in the first year of infancy, it provides for at least two subsequent re-vaccinations at intervals of from five to seven years, so that by the time a child has reached its fifteenth year it will have been vaccinated three times During epidemics of small pox, local authorities also have power, when they deem it necessary, to order the vaccination of all the inhabitants of their districts, irrespective of the vaccinations required by the law —*Sanitary Record*, May 15, 1886

A Bill to Prevent the Sale of Impure Ice has been reported by the Committee on Public Health in the Massachusetts House of Representatives It provides that upon complaint in writing the State Board of Health may, if they think the complaint is well founded, order the sale of the ice stopped

---

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY FROM MAY 22, 1886 TO MAY 28 1886

Lieut Col Andrew K Smith, Surgeon, Major Alfred A Woodhull, Surgeon, and Capt Jas P Kimball, Asst Surgeon, detailed as board to assemble at U S Military Academy, West Point, N Y, on June 1, 1886, to examine into the physical qualifications of members of the graduating class and the candidates for admission to the Academy (S O 119, May 21, 1886)

Major Albert Hartsuff, Surgeon, detailed as member of a board appointed to meet at the U S Military Academy, West Point, N Y, on June 1 and August 25, 1886, to examine into the physical qualifications of members of the graduating class and the candidates for admission to the Academy (S O 121, A G O, May 25, 1886)

Par 7, S O 120, A G O, May 24, revokes so much of par 12, S O 119, A G O, May 21, as details Surgeon Alfred A Woodhull as member of medical examining board to meet at West Point, N Y, on June 1, 1886

Capt C K Winne, Asst Surgeon granted leave of absence for twenty days, on surgeon's certificate of disability (S O 54, Dept Cal, May 17, 1886)

Capt Henry S Kilbourne, Asst Surgeon, assigned to duty at Vancouver Bks, Washington Ter (S O 80, Dept Columbia, May 15 1886)

Capt A H Appel, Asst Surgeon, ordered for duty at Ft Reno, Ind Ter (S O 52, Dept Mo, May 24, 1886)

Capt R B Benham, Asst Surgeon, ordered for temporary duty at Ft Omaha, Neb (S O 56, Dept Platte, May 24, 1886)

First Lieut R W Johnson, Asst Surgeon, ordered for duty at Ft Adams, R I (S O 45, Div Atlantic, May 25, 1886)

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U S NAVY DURING THE WEEK ENDING MAY 29 1886

Dickson, S H P A Surgeon, detached from the Naval Academy and to the "Constellation"

Simon, W J Surgeon, detached from the Naval Academy and to the "Constellation"

Kidder, B H, Surgeon, detached from the "Powhatan" and to the "Tennessee"

Rhoades, A C, Surgeon, detached from the "Tennessee," proceed home and wait orders

Cordeiro, F J B, Asst Surgeon, detached from the "Powhatan," proceed home and wait orders

Clark, J H, Surgeon, ordered for examination preliminary to promotion

Hugg, Joseph, Surgeon, detached from the "Minnesota" and granted sick leave

Beaumont, H N, Surgeon, ordered to the receiving ship "Minnesota"

Law, H L, Surgeon, detached from the "Wabash" and granted sick leave

Henry, Chas P, Asst Surgeon, ordered to the receiving ship "New Hampshire."

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U S MARINE HOSPITAL SERVICE FOR THE THREE WEEKS ENDED MAY 22 1886

Bailhache P H, Surgeon, detailed as chairman, Board for physical examination of candidates for appointment as cadets, Revenue Marine Service May 19, 1886

Wyman, Walter, Surgeon, granted leave of absence for thirty days May 14, 1886

Stoner, G W, Surgeon, detailed as recorder, Board for physical examination of candidates for appointment as cadets, Revenue Marine Service May 19, 1886

Banks, C E, P A Surgeon, leave of absence extended four days May 5, 1886

Bratton, W D, Asst Surgeon, detailed as medical officer, Revenue Str "Corwin," during cruise May 22, 1886

Perry, T B, Asst Surgeon, appointed an Asst Surgeon, May 21, 1886 Assigned to temporary duty at San Francisco, Cal May 22, 1886

ADDRESS IN STATE MEDICINE

BY JOHN H RAUCH, M D,

OF ILLINOIS

CHAIRMAN OF THE SECTION OF STATE MEDICINE

Delivered at the Thirty Seventh Annual Session of the American Medical Association, in St Louis, on May 6, 1886

Article II, Section 4 of the By Laws of the Association prescribes that the "chairmen of the several Sections shall prepare and read, in the general sessions of the Association, papers on the advances and discoveries of the past year in the branches of science included in their several sections "

In attempting to discharge this duty it will be well, first, to define State Medicine and the branches of science which it includes I have been unable to find a definition sufficiently comprehensive to cover what is conceived to be properly embraced within the scope of State Medicine Dunglison defines it to be "the medical knowledge brought to bear on State objects, as on public hygiene and matters pertaining to medical jurisprudence " In the introduction to his Manual of Practical Hygiene, Parkes, in pointing out the limitations of his subject, says "In some cases the rules of hygiene could not be followed, however much the individual might desire to do so For example, pure air is a necessity for health, but an individual may have little control over the air which surrounds him, and which he must draw into his lungs He may be powerless to prevent other persons from contaminating his air and thereby striking at the very foundation of his health and happiness Here, as in so many other cases which demand regulation of the conduct of individuals towards each other, the State steps in for the protection of its citizens, and enacts rules which shall be binding upon all Hence arises what is now termed 'State Medicine'—a matter of the greatest importance "

But in illustrating this "matter of the greatest importance," Dr Parkes clearly confines State Medicine to the relation of the State to purely sanitary matters—the protection of the individual against being placed under unfavorable hygienic conditions by the action of others, as of workmen by an ignorant or careless employer, of tenants by landlords, of food consumers by adulteration, etc, etc

De Chaumont greatly widened this definition in the preliminary lecture of his course on State Medicine, delivered in 1875 "State Medicine," he says, "has been written about, talked about, and quarrelled about, but it has rarely been explicitly defined, and to many it conveys no very distinct idea It has been confounded with public health, and generally much misunderstood, the part being frequently taken for the whole, and the wider scope of its action but little apprehended It includes the questions of public health and hygiene, general, special and individual, but its own appropriate province is such general control as will determine the several specialties in the directions most fitted for the well-being of the community In fact, we may succinctly define State medicine to be, in quasi-legal phraseology, 'the office of the sanitarian promoted by the State,'" and he predicts both its perfection and its extinction when the sanitarian as differentiated from the community generally, and the State as a controlling and interfering influence, shall have ceased to be—the one because every member of a perfected community will be a sanitarian, and the other because in such an ideal community State interference will have become unnecessary

There is still the limitation of the term "medicine" to the sanitarian in this definition, a distinction between preventive medicine—the field of the sanitarian, and curative medicine—the field of the physician But I think it is coming to be recognized that such a distinction is artificial and unnecessary, and I agree with Richardson, who, in speaking of the preventive scheme of medicine, says of the so called science and art of preventive medicine "It is not a science, it is not an art, separated necessarily or properly from curative medicine On the contrary, the study of prevention and cure proceed well together, and he is the most perfect sanitarian, and he is the most accomplished and useful physician, who knows most both of the prevention of disease and of the nature and treatment of disease, he who knows, in fact, the before and the after of each striking phenomenon of disease that is presented for his observation "

In this evolution of a definition one or two more quotations may be admissible Addressing the Association at the Atlanta meeting in 1879, on "The Regulation of Medical Practice by State Boards of Health as Exemplified by the Execution of the Law in Illinois," Dr H A Johnson suggested, in his conclusion, "that it is the duty of the State to protect its citizens from the injuries they may sustain from the practice of incompetent physicians and surgeons, as well as from any other source of danger to public health" And in the summary prefacing the Sixth Annual (1883) Report of the Illinois State Board of Health, it is observed that "Boards of health are created and maintained for the conservation of the interests of health and life Ordinarily their functions are limited to dealing with sanitary questions, with the removal of the causes of preventable disease and premature death This Board, however, is also charged with the execution of the act to regulate the practice of medicine in the State, and thus the medical profession, one of the most important agencies which is concerned with the interests of health and life, is brought within the scope of sanitary legislation To improve the status of the individual practitioner, and to develop a well trained and thoroughly educated medical profession, must result in increasing the value of this force in sanitary science and public hygiene, a force which, in the nature of things, must always exist so long as there are physicians and patients, and the character and influence of which must always hold a direct relation to the tone, the attainments, and the competency of those by whom it is exerted"

The application of the term State Medicine is thus seen to have been successively extended from the agency of the State in matters of hygiene beyond the control of the individual, first to measures of preventive medicine in general, and thence to curative medicine in so far as it is the duty of the State to regulate medical practice State Medicine may therefore be now defined as the connection of the State with "*that branch of science which relates to the* PREVENTION, CURE *or* ALLEVIATION *of the diseases of the human body*"[1] It embraces not only all public sanitary measures, but also the practice of medicine in so far as this is regulated by the State Therefore, any report upon "the advances and discoveries of the past year" in the branches included in this Section may logically begin with the subject of the regulation of medical practice, which also and necessarily includes the subject of medical education

STATE REGULATION OF MEDICAL PRACTICE AND MEDICAL EDUCATION

Before proceeding to discuss the present status and recent progress in these matters, it may be well to set forth, briefly, the authority by which the State assumes to regulate the practice of medicine That authority is the inherent and plenary power which resides in the State to prohibit all things hurtful, and to promote all things helpful, to the comfort, welfare and safety of society Speaking specifically of the Illinois Medical Practice Act, ex Governor John M Hamilton has recently said "The object of the Medical Practice Act was primarily a police regulation Incidentally it was educational Primarily the purpose of the law was to rid the State of incompetent, ignorant and dangerous mountebanks and quacks, who were carrying on a fraudulent and nefarious business by all manner of deceit in a pretended practice of medicine among the people It was to protect the lives, the health, the morals and the property of the people of the State from the shameless depredations of swindlers and adventurers who, by all manner of false representations and deceptive promises, were taking advantage of the misfortunes of the people in sickness and ailments of all kinds, to still further injure their health, endanger their lives and rob them of their money

"Incidentally the law was designed to require a reasonable amount of education to fit one for the practice of medicine before he should be allowed to enter that profession, so directly and intimately connected with the lives, the health and the happiness of the people Both these purposes come clearly within the police powers of the State in affording such protection to its citizens"

An unbroken line of authorities, from Blackstone down to the most recent decisions of the various Supreme Courts, hold that the police powers of the State are plenary and inalienable, co extensive with the natural right of self-protection, that their exercise is demanded and justified by the "law of over ruling necessity," and that broadly, they are the foundation of all laws and regulations for the well-being or government of the people, and especially, of all laws, ordinances, rules and regulations for the preservation of the health or safety of the community Early in the history of the country laws, thus founded, were enacted for the regulation of the practice of medicine But the sparse population and the conditions which then obtained, as well as the fact that many of the enactments were so onerous and restrictive that they came to be regarded by the public as in the nature of class legislation, operating to make the profession a close guild or trades union, rendered their enforcement impracticable They were gradually repealed or fell into a state of "innocuous desuetude," until about 1830–1840 there were practically no restrictions, the profession became a "free for all," bogus diplomas were openly and unblushingly sold and displayed by their purchasers, as credentials of membership in a learned profession The country was overrun by hosts of ignorant, immoral and dangerous swindlers, self-styled "doctors," who preyed upon the unfortunate afflicted, "isms" and so called "schools" of medical practice multiplied, a mushroom crop of diploma-mills sprang up over the land, and as a natural result, the general standard of medical education and of requirements for graduation—except among the best class of medical colleges—fell lower and lower

A reaction from this condition began at about the close of the first century of our National existence, at which time, 1876, North Carolina had a well framed law, creating a State Board of Medical Examiners, passed in 1859 Kentucky had enacted a law in 1874, creating district examining Boards, but except in a few counties, this soon became a dead letter In In 1875 Nevada, and in 1876 California and Texas legislated upon the subject In 1877 Alabama established a State Board of Medical Examiners, and Illinois passed a Medical Practice Act the execution of which was devolved upon a State Board of Health created by a separate enactment Within the next two years only two other States took action—Kansas in 1879 (repealed in 1881) and New York in 1880 In 1881 nine States and one Territory enacted medical practice laws, viz.: Arizona, Arkansas, Colorado, Connecticut, Florida, Georgia, Nebraska, New Jersey, Pennsylvania and Wisconsin. In 1882, Louisiana, Mississippi, New Hampshire, New Mexico, South Carolina, West Virginia and Wyoming; in 1883, Delaware, Michigan, Minnesota and Missouri; in 1884, Dakota and Virginia, and, since the last meeting of the Association, Indiana and Iowa have swelled the total to thirty-three States and Territories of the Union, which now exercise some degree of legislative control over the practice of medicine within their borders.

---

[1] The quotation is the definition of *medicine* according to Webster

The general drift and tendency of this legislation are toward securing a recognized standard of professional attainments, evidence of which—with a few notable exceptions—is afforded by the presentation of a diploma of graduation from some legally chartered institution in good standing; or, in the absence of this, an examination more or less strict, in the various fundamental branches of medical science. The exceptions are in the States of Alabama, Mississippi, North Carolina and Virginia, where the diploma is ignored, and the applicant for admission to practice must establish his possession of the necessary skill and ability so far as an examination may determine the same.

As an evidence of fitness and qualification the diploma must obviously vary in character with the character of the institution by which it is issued. Medical instruction in this country is almost entirely a matter of private enterprise, and until within a few years, numerous "colleges" with the briefest of lecture-terms, conducted by the scantiest of faculties—in which one man often played many parts—innocent of clinical, surgical or anatomical material, and with the most charitable of examinations have graduated into the profession all who could pay the necessary fees and armed them with the talismanic diploma.

Since 1765 a total of 224 medical educational institutions have been founded—not established—in this country, of which number 105 are now fortunately extinct. There are still remaining 120 medical schools of all kinds in the United States, and among them, it is only fair to say are some in which the course of instruction, the facilities and the competency of the teachers are as high as anywhere in the world. Within the last twenty years there has been, in fact, a marked and gratifying improvement in the standard of medical education. I quote a few illustrations of recent improvement from my last report on "Medical Education in the United States and Canada." There are now 93 out of the existing 120 colleges in the United States, which exact an educational requirement as a condition of matriculation; in the first report there were only 45. Attendance on three or more lecture courses before graduation is now required by 24 colleges, as against 12 heretofore; and provision is made for a three or four years graded course by 58 others. Hygiene is now taught in 91 colleges, and medical jurisprudence in 97, as against 42 and 61, respectively, heretofore. The average duration of lecture terms has increased from 23.5 weeks to a fraction over twenty-five weeks; 7 more colleges have lecture terms of five months or over, and 10 more have terms of six months or over as compared with the sessions of 1882–1883.

While much of this progress is due to a general and increasing desire on the part of the profession to raise the standard of attainments necessary to enter its ranks, and to the enforcement of certain requirements in States which have enacted laws regulating the practice of medicine, it will not be invidious to attribute a fair share to the adoption in 1880, by the Illinois Board of a schedule of minimum requirements, enforced since 1883, and which prescribes that a medical college, in order to be held in good standing for the admission of its graduates to practice in Illinois, shall exact such a general preliminary education of the intending student before his admission to the lecture room, as will enable them to comprehend the instruction therein given; and shall issue its diploma conferring the degree of M.D., only upon the completion of such curriculum of study—as to the branches of medical science taught, the duration of the reading, and of lecture-terms, and the amount of practical instruction in hospital and at the bedside—as obtains in the average medical school.

Minnesota, Missouri and West Virginia exact substantially the same standard, and the work of the Minnesota Board especially has been wide-reaching and beneficial in this respect. The Iowa law, just enacted, confers similar powers, and the influence upon medical education of this group of States—Minnesota, Missouri, Iowa and Illinois—in establishing a uniform test of the "good standing" of a medical college, must be felt throughout the country. Fully one third of the new graduates every year settle in the West, and colleges must, perforce, take cognizance of this fact.

While the schedule of minimum requirements does not set up so high a standard as that aimed at by the American Medical College Association, it has the advantage of applying to all schools of medicine and of having been successfully enforced for three years. Furthermore, it is susceptible of modification, and the question is already being considered whether the time is ripe for a further advance. Until within a short time there had been, for sixty years, no marked departure from the orthodox three years of study and two courses of lectures as the requirements for graduation. But, as already shown, there are now twenty-four colleges which practically require four years of study and attendance upon three terms of lectures, and fifty-eight others which make provision for a similar extended course. The domain of medicine has so far widened its borders, especially within the present generation, that the methods and periods of study which sufficed thirty or forty years ago are no longer adequate.

A low standard of medical education, and the absence of uniform legal requirements are also responsible, almost exclusively, for the overcrowding of the profession. Did time suffice it would be interesting to present this matter in detail, but I can now only glance at some of the results of my study of this phase. In 1880 there were, according to the National census, 83,436 physicians in the United States. Since that date there have been added—exclusive of the foreign increment—23,531 new graduates, not including those of the last session, 1885-1886 This makes a total of 106,947, and is an annual increase of over five and one-half per cent while the annual increase of population is less than two per cent The annual death rate—basing that of the country at large upon the Illinois rate, which I have pretty accurately determined to be 12 38 per thousand—is less than that of adult males engaged in all occupations, and the difference will probably fairly balance the loss by those who retire from practice on account of old age, physical disability, and other causes not connected with the question of fitness and professional success

It will, then, be within bounds to say that the excess of the per centage of new graduates over the per centage of increase of population represents the number of unnecessary recruits to the ranks of the profession every year

The answer to the question, What becomes of them? is indicated by these figures concerning the profession in Illinois

June 14, 1880	
Total number in practice as shown by Official Register of that date	5,979
Total number of new certificates issued to new men up to February 10, 1886	2,063
Total number to be accounted for	8,042
February 10, 1886	
Total number in practice as shown by Official Register of that date	6,065
Total number died	344
" " left the State	1,061
" " abandoned practice	572
	8,042

That is to say, over seven per cent of the entire number failed as physicians and sought other modes of obtaining a livelihood It is noteworthy, by the way, that non graduates fall out in much larger proportion than the graduates, and that the graduates of three-course schools show the smallest per centage of loss, either by removal from the State or by abandonment of practice

Here are some instructive figures for Chicago In 1880 there were certificates issued to 172 new comers, five years later only 84 of these remained—a loss of over one half In 1881 there were 183, in 1882, 171, 1883, 209, and in 1884, 198 new comers, and in 1885 there remained of each year's group, 97, 116, 145, and 168, respectively In one year the loss was 15 per cent , in two years, 30 per cent , in three years, 32 per cent , in four years, 47 per cent , and in five years over 51 per cent

There are from 1500 to 2000 physicians in the State of Illinois more than are necessary to supply the legitimate demands for professional services, and who are not earning a comfortable livelihood from legitimate professional exertion And what is true of Illinois is probably substantially true of every State in the Union I will not stop to dwell upon the demoralizing effect of this condition—demoralizing to the individual, to the profession, and to the public Instances of this demoralization must be familiar to every member of the Association

On the other hand, and by way of contrast, I wish to add one further illustration from my personal experience During the past nine years my official position has made me familiar with the professional history and status of over 13,000 men, more or less directly connected with the practice of medicine in Illinois I have followed up, with especial interest and care, the careers of 789 out of 1000 physicians who studied four years and attended three terms before graduating These are, with few exceptions, the successful and prominent members of the profession in the different communities in which they reside They are well equipped by general education, by an ample period of professional study, by didactic and clinical instruction, and by hospital practice They are successful, as a rule, because they have fitted themselves to command success, and this Association can do few things more directly in the interest of the public and of the profession than to exert its further influence to increase their number while decreasing the number of the opposite class

The foregoing considerations seem to me to lead logically to the following conclusions

1 That the best interests of the public welfare demand the highest attainable standard of educational qualifications, skill and ability, as well as of professional and personal honor, integrity and morality, among those engaged in the practice of medicine

2 That it is the duty of the State to exercise the inherent plenary power and *authority which it possesses* for the protection and promotion of the public welfare, to secure such standard

3 That uniform State laws, exacting of every one aspiring to practice medicine proof of personal fitness and professional competency, would prove the most potent agency in improving the standard of medical education and in enhancing the dignity and usefulness of the medical profession

Specifically, I wish to suggest

That the American Medical Association should put itself upon record at this session as recommending the extension of the period of study to four years and of attendance upon lectures to three full terms, with ample hospital practice and clinical instruction, as the requirements for graduation in medicine,

That the Section on State Medicine be instructed to frame a law for the regulation of the practice of medicine, which law, when endorsed by the Association, shall be the standard with which all existing legislation on this subject should be made to conform as speedily as practicable, and which shall be urged for adoption by those States where no such law now exists

Whether such a law should establish a single State Examining Board, which, independent of any influence from the teaching interest through a diploma or otherwise, should admit to practice only upon actual examination, or whether the diploma of a college in good standing should be accepted as proof of necessary qualifications, are questions for earnest consideration If the policy of those States which are enforcing a standard of requirements whereby to test the good standing of a college, be continued in good faith and with as much effect during the next twenty years as during the past three, there would be little to choose between the two modes But before an independent Examining Board, intent only upon ascertaining the applicant's moral and professional fitness, the graduates of all colleges would stand alike upon their individual merits The effect would be to encourage the tendency to make the science of medicine as exact as it is complex, and to obliterate much of the element of empiricism which still justifies the use of the term "art" in its designation

By either mode the State may promote the public welfare, and through a wise regulation of the practice of medicine elevate the standard of medical education, which is the foundation of the practice And it seems to me especially fitting that the American Medical Association should again make its influence felt in this direction Its earliest labors, and among its most important and successful, were devoted to securing a "uniform and elevated standard of requirements for the degree of Doctor of Medicine" Its further efforts at this time should be attended with even greater success

ADVANCES AND DISCOVERIES IN PREVENTIVE MEDICINE

While there has been this marked and gratifying improvement in the branches thus far considered—now clearly recognized as belonging to the domain of State Medicine—the past year has witnessed equally satisfactory practical advances in the more familiar province of Preventive Medicine The number of sanitary organizations, both legal and voluntary, has increased, the contributions to sanitary literature have been numerous and valuable, and professional and public interest and effort have been enlisted as never before in attempts to remove or abate the preventable causes of disease, and to discover and perfect safeguards against the great pestilences To a great extent this has been stimulated by the prevalence of Asiatic cholera in some parts of Southern and Western Europe, and the consequent dread of its extension to our shores Fortunately, the apprehensions entertained at the date of the last meeting of the Association have not been realized, and the country has been practically free from any general or noteworthy epidemic, notwithstanding the prevalence of smallpox in some parts of Canada

State and Municipal Boards of Health have generally done effective work in their respective spheres In some States a general sanitary survey has been undertaken, and in many cities, towns and villages house to house inspections have been pushed, and the nuisances and defects thus disclosed, both of a public and private nature, have been largely remedied As was frequently remarked during the past summer and fall, an amount of general and local "cleaning up"—which is the essence of sanitation—was accomplished, which could not fail to have an appreciative effect upon the public health Unfortunately, the subject of the registration of vital statistics is in such an imperfect and unsatisfactory condition in this country that it is not possible to give any comparative figures by which to measure this gain for the whole country, but the mortality returns of the large cities generally show a reduction in the death-rate of 1885 as compared with the average death rate for several years previous

Four more State Boards of Health were established in 1885–86, the list now comprising the following thirty one organizations, the dates of the establishment of which are prefixed In 1869, Massachusetts,[1] in 1870, California, in 1872, Michigan, Minnesota, in 1873, Alabama, Wisconsin, in 1874, Maryland, in 1876, Colorado, Louisiana, New Jersey, in 1877, Illinois, Mississippi, Rhode Island, Tennessee, in 1878, Connecticut, Kentucky, North Carolina, in 1879, Delaware, Iowa, South Carolina, in 1880, New York, West Virginia, in 1881, Arkansas, Indiana, New Hampshire, in 1883, Missouri, in 1885, Dakota, Kansas, Maine, Pennsylvania, and in 1886, Ohio

These Boards, it is proper to remark, owe their existence largely to the influence of the American Medical Association, which has for years actively promoted their organization

While States and municipalities are thus generally exerting themselves for an efficient protection of the public health, our National health service remains in a very unsatisfactory condition Notwithstanding the efforts of the profession generally and of many health organizations to secure action by Congress for the remedy of this condition of affairs, nothing definite has yet been done Three different bills have been introduced during the present session, but there is little hope of either of them receiving favorable consideration

One thing remains clear Whether by the rehabilitation of the National Board or by the creation of a new organization, it is the imperative duty of Congress to complete the health defenses of the country Municipalities have their legitimate sphere within which they alone can act and are responsible, and next beyond which the authority and resources of the State are demanded But neither municipalities nor States can protect themselves against foreign pestilences without the assistance of the National authority, nor can they properly guard themselves against inter State infection or contagion without the cooperation of the same authority I have already dealt with this subject fully in an address before the National Conference of State Boards of Health in 1884, on the "Prevention of the Introduction of Asiatic Cholera," in a report made in the early part of the present year on our "Coast Defences against Asiatic Cholera," and elsewhere

Among the voluntary organizations the work of the American Public Health Association during the year has been of more than usual practical value The Lomb Prize Essays, and especially the "Report on Disinfectants and Disinfection," are substantial additions to sanitary knowledge The Sanitary Council of the Mississippi Valley has not been called upon for action, but its organization is preserved ready for an emergency Nothing definite was accomplished at the last National Conference of State Boards of Health, which was held during the Washington meeting of the Association

---

[1] This Board is now separated from the Board of Lunacy and Charity with which it had been associated since 1878

Abroad, a second series of sessions of the German Cholera Conference was held in Berlin, May 5–7, 1885, at which the subjects of the etiology and prevention of cholera were discussed by Koch, Pettenkofer, Virchow, Hirsch, and others, but without eliciting much which was new, or settling any of the mooted questions Prof Koch summarized the chief measures to be taken against the disease, and which, so far as they go, do not differ from those adopted by good sanitary authority in this country They dealt, however, exclusively with the local safeguards of sanitation, disinfection, isolation, supervision, etc , and ignored measures of exclusion of the disease by notification, maritime sanitation, supervision of ports of embarkation, and quarantines of inspection, observation and sanitary work at ports of arrival

Following the adjournment of the Berlin Conference, an International Sanitary Conference was held at Rome under the auspices of the Italian Government Although its paramount object was the discussion of questions relating to the prevention of cholera, the subject of yellow fever was also considered in the same relation, through the efforts of the American delegate, Dr George M Sternberg The delegates were of two classes, diplomatic and technical or professional, and at an early stage a Technical Commission was formed, which finally agreed upon substantially the same measures that advanced sanitarians in this country consider necessary for the limitation and suppression of cholera, yellow fever, and other communicable diseases which, under bad sanitary conditions of vessels and places, may become epidemic The exceptions to such agreement were the English delegates, composed of gentlemen whose experience with cholera had been mainly limited to India, and who, in consequence, deny the communicability of the disease through human intercourse, deny the infectiousness of cholera dejecta, and pronounce disinfection a farce and unscientific

The Conference adjourned to meet again in the fall, but this intention was not carried out As I have heretofore observed, the practical benefit to be derived from these conferences—in the absence of authority to make an international sanitary convention, binding upon all interested—is the interchange of views, the dissemination of knowledge, and the formulation of such views and knowledge So far as this country is concerned, they have not changed the status in any respect We must continue to rely, for the exclusion of cholera and other Old-World pestilences, upon such precautionary measures as can be secured at ports of arrival

The International Congress of Hygiene, which has been held successively at Brussels, Paris, Turin, Geneva, and the Hague every alternate year for the past ten years, and which should have been held this year at Vienna, has been postponed until 1887, for some reason not yet announced

With the object of determining to what extent such precautionary measures may be secured, especially against Asiatic cholera, I have made an inspection of the quarantine maintained upon the Atlantic and Gulf coasts from the St Lawrence to the Rio Grande The results of this inspection have been published by the Illinois State Board of Health, and as the report is accessible to the members I will confine myself on this occasion to the following conclusions I am more than ever convinced, since completing this inspection, that Asiatic cholera, as well as small pox and yellow fever, may be effectually excluded from the United States by an intelligent use of the agencies still at our command This is not a matter of speculation or theory A great advance has been made in practical sanitary science since 1878—notably in the administration of the maritime quarantines generally, and especially in the improved safeguards at the mouths of the St Lawrence and the Mississippi A quarantine of exclusion of the three principal epidemic diseases is now a matter of certainty, depending upon prompt notification of threatened danger, vigilant supervision over commercial intercourse with infected localities, inspection of all immigrants and the enforcement of their vaccinal protection, sanitation and purification of infected vessels and cargoes, isolation of those sick with these diseases, the surveillance of suspects during the periods of incubation, and the employment of other well defined preventive and precautionary measures which now constitute the best modern sanitary practice as applied to maritime quarantine

It must be repeated, however, that the cooperation of the National Government with State and local authorities, as well as its independent action in matters beyond the reach of States and municipalities, are indispensable to the proper protection of the public health The duty of Congress in this connection is even more pressing than the responsibility of providing defense against an armed enemy This latter is a more or less remote contingency, but the assaults of foreign pestilence are constant and continuous

Thus far we have been providentially spared an invasion of the Asiatic plague which is now filling Great Britain and Europe with anxiety and the real extent and prevalence of which we do not know The State Department has, within a few days, been requested to appoint sanitary inspectors at the United States consulates at Genoa, Naples, Marseilles and Venice, with instructions—in the language of the dispatch—"to give prompt information of the appearance of cholera in any of the consular districts named, and to report the departure of emigrants and merchandise for the United States from infected districts" But it is already known that the disease exists, and has for months, in several provinces of Italy, including Venetia—cases having been reported in Venice even in January last, it is known that the entire Mediterranean littoral is practically an "infected district," and that the northward march of the pestilence is causing alarm in Austria, Germany, Northern Europe generally, and in Great Britain The appointment of sanitary inspectors at one French and three Italian ports hardly seems adequate to the occasion At no time since cholera was announced at Toulon in 1883 has this continent been in as serious danger of an invasion of the disease as it is now And not alone does cholera threaten, but small pox is epidemic in many districts with which we are in direct and frequent communication [1]

I cannot close the consideration of this branch of my subject without a brief reference to the obvious necessity of National control of immigration Sanitary science and public hygiene touch both the individual and the National life at many points It is a question which is daily and hourly becoming more urgent—as the columns of every issue of every newspaper show—how much longer it will be safe or prudent to continue the unrestricted influx of the vicious, the insane, the pauper and the infected immigrant into our midst I will not attempt to discuss so momentous a question at the present time and amid the multiplicity of other topics I have already on more than one occasion expressed my views concerning it Neither the sanitarian nor the statesman can afford to longer ignore its consideration

The By Law calls for a report on the "advances and discoveries of the past year in the branches of science included" in the Section While the workers have been active and their labors faithful in many directions, it is to be feared that the discoveries in preventive medicine are too intangible or too incomplete to warrant much of positive statement There are new theories and claimed discoveries concerning malaria cholera, yellow fever, hydrophobia, tuberculosis and other diseases But whether Klebs and Crudeli or Marchiafava or Celli have found the malaria germ, whether Koch and his followers or Klein and his *confreres* are correct as to the causative connection of the comma bacillus with Asiatic cholera, whether Domingo Freire and Carmona are to share the obloquy of Ferran or the honors of Pasteur, whether bacteria themselves, or only their products, or whether neither one nor the other, but ptomaines and leucomaines produced by normal vital action, are the morbific agents of disease against which the sanitarian must direct his energies—these and similar questions are yet *sub judice*

The etiology of such common diseases as diarrhœa and diphtheria are still equally obscure, although some light seems to be thrown upon the origin of certain outbreaks of the latter disease by the observations of Dr Cresswell, who, in a paper recently read before the London Epidemiological Society, thinks he has traced six outbreaks of diphtheria, for which there was no other obvious explanation, to persons suffering from chronic tonsillar inflammation following attacks of diphtheria, and concerning whom he asks "Do the violent reactions of the tonsils of these persons to weather changes involve likelihood of rendering them diphtheritically infectious?" In other words, May diphtheria become chronic and liable to periods of infective recrudescence? The question acquires additional importance for the medical officer of health from the fact that the disease is unmistakably increasing in frequency and in its influence upon the death-rate

On the other hand, bacteriology may fairly claim to have advanced the science of water analysis, which no longer depends upon chemical and microscopic examination, but for the purposes of the sanitarian must be submitted to the further test of biologic experiment It has also certainly been of service in raising the art of disinfection to the level of an exact science, and the labors of Sternberg, Smart, Salmon and others in the bacteriological field in the United States, are not unworthy of comparison with the work in Europe

A reaction, however, seems to be setting in against the sweeping claims of the bacteriologists, and the assertion, for example, that the typhoid bacillus, after twenty years of experiment, has at last been demonstrated to be the true typhoid germ, will not stand the criticism of Prof von Pettenkofer, who, in a recent address on the relationship between bacteriology and epidemiology, points out that the entire environment of a micro organism and all the conditions which influence its growth, development and results, must be taken into the account, and that the mere fact of setting up a certain train of symptoms in a lower animal analogous to those observed in the human subject is by no means conclusive proof that the specific fungus transmitted from the one to the other is the sole cause of the disease in the higher organism In this address, which, like all of his contributions to scientific hygiene, is replete with food for thought, Pettenkofer asks what the study of bacteriology has done in advancing practical sanitary measures, and pertinently cites Lister's antiseptic system and Pasteur's rabic inoculation as instances of practical results accomplished without demonstrating the existence of a special form of bacteria or the actual morbific agent He might still more strikingly have referred to Jenner's immortal discovery

Concerning this subject of vaccination I beg to call the attention of the members to the additional proof cited in recent reports of the Illinois Board, of the superiority of humanized virus, not too far removed over bovine, in cases demanding promptness and certainty of action I think this practical point cannot be too strongly insisted upon, and it may be well to repeat, as a fitting conclusion of this address, my remarks on this subject in the paper on "The Relations of Small Pox and Vaccination" in the Fifth Annual Report of the Board (p 502) Treating of the promptness of action in the face of exposure it is there shown that humanized virus may be depended on much more certainly than bovine to act promptly Usually on the second or third, very seldom so late as the fourth day after the insertion of good humanized virus, the papular stage of vaccination will begin, and be followed, with almost unvarying regularity, by complete development of the vesicle on the eighth day, and by the subsequent appearance of the "index of safety"—the specific inflammation of the skin, or stage of areola Bovine virus, on the contrary, is subject to all degrees of delay, even to periods of weeks During the epidemic of 1881–83 this defect of bovine virus was more than once followed by serious consequences Not alone were lives lost among the exposed members of isolated families, where vaccination was resorted to early enough to have averted an attack had the virus acted promptly, but epidemic outbreaks followed under similar circumstances—that is, in localities where, upon the discovery of the first case, vaccination of all unprotected or exposed was at once resorted to, with bovine virus, but which either proved so tardy in its action, or so totally inert, as to allow the disease to gain a foothold

---

[1] It is worthy of passing note that cholera has invaded a new continent within the past few months Its introduction into Australia where it had been hitherto unknown furnishes a fresh proof if any were necessary of the transportability of the contagion of the necessity of supervision over maritime travel and commerce and of the importance of being prepared to meet and properly deal with an infected vessel upon its arrival

"The loss of a day," says Seaton in his Hand book of Vaccination, "may be the loss of a life" Hence the necessity for using virus which will act promptly, and not remain latent three, five or any other number of days Recent experience corroborates observations made during the period from 1866 to 1873, while Sanitary Superintendent of the city of Chicago, to wit That it is never too late to vaccinate after exposure, short of the actual appearance of the variolous eruption If the vaccination be performed within three or four days after exposure, and the areolar stage, the index of safety, be reached in the normal time, an attack of small-pox will almost invariably be averted With every additional day's delay the protective power will be weakened, but, contrary to the opinion laid down in the text books, experience proves that this protective power is not entirely exhausted until the vaccination is deferred at least up to the beginning of the febrile stage of small pox

Of 323 cases of small pox, tabulated in the preceding pages, in which the patients had never been vaccinated until after exposure, 305 recovered and 18 died, being a less mortality rate than among the 690 cases, which occurred among those who had been vaccinated before exposure only In some of these cases vaccination was not attempted until shortly before the beginning of the eruptive stage A reference to the Notes appended to the Tabular Statement of 1,100 cases, pages (296–327 inclusive), will show many instances where vaccination after exposure was successfully resorted to after the expiration of the period ascribed by Marson, Seaton, and others, as the limit beyond which, "whatever the local success of the vaccination, no constitutional effects will be imparted" In these Notes will also be found the details of cases where the attempt to vaccinate with bovine virus was only successful after one or more repetitions, with loss of valuable time or where such attempt finally proved wholly unsuccessful With the exception of one group of six cases—a family vaccinated by the father, a layman—all the vaccinations performed with humanized virus, after exposure,' were successful, and the patients recovered, with mild attacks of short duration But of such vaccinations with bovine virus, over 40 per cent were failures—that is, in the sense of manifesting activity before the variolous disease began—and of this 40 per cent of failures there was 30 per cent of fatal results

The general tenor of these views is also supported by the figures given in the January number of the *American Journal of the Medical Sciences*, quoting from the "Arbeiten aus dem Kaiserlichen Gesundheitsamte" "The increase of unsuccessful vaccinations in the German Empire was due to the vaccinations in the Grand Duchy of Hesse, where, owing to the introduction of animal lymph, the number of successful vaccinations decreased from 97 31 per cent, in 1881, to 63 44 per cent, in 1882" And the German Commission on Vaccination report—"*For* vaccination with humanized lymph may be mentioned the certainty of its action, the symplicity of its machinery, the inexpensive manipulation of the lymph *Against* the use of animal lymph may be taken the less certainty of its results, a more complicated machinery and the greater cost of production of lymph" Nevertheless the Commission conclude that animal "is capable of supplying the place of humanized lymph" Commenting upon this, Dr Buchanan, the medical officer of the Local Government Board, in his last report (1884) says "In England, these are identical when the operation is done directly from arm to arm, or calf to arm, thus, two operators at the Animal Vaccine Establishment, in London, produced an average of 988 vesicles for every 1000 insertions of calf lymph made on infants Now the employment of stored lymph reduces this average by some 20 or 30 per cent, whether humanized or animal lymph be used Direct vaccination from calf to arm is only possible in large centres of population In sparsely inhabited districts the use of stored lymph becomes a practical necessity, unless arm-to arm vaccination be resorted to, hence, there is much probability that the decision of the German Commission will tend to reduce the condition of the German people, as to protection against small pox, to the condition of the inhabitants of the Grand Duchy of Hesse"

I see no reason—but the contrary—for modifying the judgment expressed in the eleventh of the propositions, concluding the paper above referred to

"That the relative advantages of bovine and of humanized virus are still *sub judice* as to the most important point, namely their comparative protective powers Humanized virus has been tested for more than eighty years, bovine for about sixteen The former descended in an unbroken line of vaccinations from the original operations of Jenner, still produces the same typical results, the same regular sequence of phenomena, as those obtained by Jenner himself, the latter produces almost as many varying results as there are propagators In cases of emergency, where promptness of action is important, the preference must be given to the humanized"

SYPHILIS IN ITS RELATIONS TO DENTAL AND ORAL SURGERY[1]

BY G FRANK LYDSTON, M D,

PROFESSOR OF SURGERY IN THE NORTHWESTERN COLLEGE OF DENTAL SURGERY LECTURER ON GENITO URINARY AND VENEREAL DISEASES IN THE COLLEGE OF PHYSICIANS AND SURGEONS CHICAGO ILLINOIS

The time is long since past when an apology was necessary for bringing a subject of general surgery before a convention of dental and oral surgeons Dental and oral surgery has of late years, come to be recognized as a specialty of general surgery, and most justly so The progressive dentist of to day is earnestly striving to attain all of the qualifications necessary to the true specialist, who has been so aptly described as a practitioner "who knows something of everything, and everything of something" There is perhaps no specialty that involves more of the principles of general medicine than that of dental surgery It is greatly to the credit of the dental tal profession that it is now recognizing this fact

---

[1] Read in the Section of Dental and Oral Surgery on May 4 at the Thirty Seventh Annual Meeting of the American Medical Association

There is perhaps no general disease which figures as a more important factor in dental and oral practice, than syphilis The prevalence of this disease, as revealed to the general surgeons and specialists of our large cities, is somewhat appalling, and when we stop to consider its insidiousness, the importance of the subject is at once appreciated The oral symptoms of the disease, in well managed cases, are nowadays the most important of all the local manifestations which characterize its active period The reasons for this are at once apparent The vast majority of well treated cases will escape skin lesions altogether, or at most will have nothing more severe than the roseola, which is of the most trifling importance, but very few indeed will be found to go through a course of syphilis without being afflicted with oral symptoms of greater or less severity Such, at least, has been my experience in quite an extensive field of observation The argument may be advanced that this statement applies only to the better class of patients, but it is just this class whom the dentist is most frequently called upon to treat When the facts seem to controvert the proposition which has been advanced, they seem to be the result of causes independent of the intrinsic severity of syphilis Another consideration that tends to enhance the importance of the oral syphilides, is the fact that it is through these lesions that innocent persons are most apt to become infected

In the matter of prophylaxis of oral lesions in syphilis, the function of the dentist is acknowledged by progressive specialists, to be of paramount importance The patient who would go through a course of syphilis and of treatment therefor, with a minimum of suffering, will place himself in the hands of his dentist, as preparatory to undergoing strictly medicinal treatment The patient with tartar about the teeth, carious cavities, or sharp or rough surfaces upon the teeth, jutting against the buccal mucous membrane or tongue, is almost sure to suffer from luxuriant crops of mucous patches, or destructive ulcerations In addition to this inconvenience, we will find that under the faulty conditions mentioned, reflex excitation of the salivary and mucous glands is constant, and when, under such circumstances the stimulating effect of mercury is superadded, ptyalism or even stomatitis, is quite likely to occur With the teeth and gums in bad condition, the patient is usually so intolerant of mercury that he cannot take a sufficient quantity to benefit his syphilis

In passing, it may be well to caution against carelessness in the matter of cleansing all instruments used in dental practice, whether the patient be known to be syphilitic or not Syphilis is so widely disseminated, even among respectable people, that it is unsafe to run any risk in the matter The oral lesions of syphilis are very actively contagious during the early months of the disease, and it has been supposed that they retain their contagious properties for a much more prolonged period than do other lesions A lesion so insignificant as to escape attention, may give rise to a highly contagious secretion This secretion becomes mingled with the saliva and may adhere to instruments for an indefinite time Just how long the contagium may retain its vitality is unknown, but it is probably a prolonged period I am happy to say that very few, if any, accidents have been laid at the door of the dentist, but that fact should not render him one whit less cautious I have myself seen one case in which there were strong grounds for suspicion of infection by dental instruments It is to be said, however, that the dentist in question was not a reputable member of the profession

A certain preventive of such accidents is to dip all instruments in pure carbolic acid, both before and after using, in addition to the ordinary measures of cleanliness Ordinary solutions of antiseptics are too weak to be efficacious Iodine and bichloride of mercury corrode the instruments, and the flame of the alcohol lamp destroys their temper, hence pure carbolic acid is the most efficient and available antiseptic If prepared in the manner suggested, infection from instruments is impossible A safe rule in surgery is to avoid the use of an instrument which we would hesitate to put in our own mouths, or thrust in our own flesh, if necessary

In beginning the discussion of syphilis as an etiological factor in dental and oral lesions, it is proper to consider the question of hereditary syphilis This is a subject of much more importance to the dentist than is generally supposed It has long been well understood that syphilis is capable of producing marked disturbances of the nutrition and development of the teeth This fact has been developed chiefly through the efforts of the renowned syphilographer, Mr Jonathan Hutchinson, of London It may seem presumptious to criticise anything emanating from so eminent an authority, but it is my humble opinion that Mr Hutchinson's description of the teeth and facies of the syphilitic child, has tended to mislead us Observe his original description "The permanent teeth are irregular and defective, they are small, vertically notched, rounded at the corners or pegged, and are often marked with seams and ridges or lines, of a dirty brownish color These characters are especially marked in the central incisors, which are the test teeth" He further says "Next in value to the malformation of the teeth, are the state of the patient's skin, the formation of his nose and the contour of his forehead, the skin is almost always thick, *pasty and opaque* *It also shows* pits and scars, the relics of former eruptions, and at the angles of the mouth are radiating linear scars, running out into the cheeks The bridge of the nose is almost always low, and broader than usual, often it is remarkably sunken and expanded The forehead is usually large and protuberant in the region of the frontal eminences, often there is a well-marked depression just above the eyebrows The hair is usually dry and thin, and now and then the nails are broken and splitting into layers"

It would be interesting to know how many cases each of the gentlemen present have had under observation, that tallied with the above description Exceptionally, indeed, has it been my privilege to observe such a *tout ensemble* of symptoms, yet it has been my lot to observe and treat many unequivocally syphilitic children It has been the custom to look for Hutchinson's test teeth, seldom indeed are they found, ergo, the patient is not syphilitic

Now, as a matter of fact, the children who are so badly affected with syphilis as those described by Hutchinson, seldom arrive at the period of dentition, for the vast majority of the victims of severe hereditary syphilis fail to survive the third month after birth It is the child who suffers from attenuated hereditary syphilis who survives, and it is with him that the dentist has to deal, hence the extreme cases described by Hutchinson are not fair criteria of the effects of syphilis upon the teeth, as seen in dental and oral practice, although such cases may be met with

When I use the term attenuated syphilis, I mean hereditary infection not severe enough to cause typical syphilitic lesions, but severe enough to cause mal nutrition Like all conditions of perverted nutrition occurring during the period of dentition, that produced by hereditary syphilis gives rise to defective and irregular development, faulty texture, and early decay of the teeth The syphilitic cachexia is preeminently liable to produce such results but unfortunately there is nothing characteristic in the resulting physical appearances, in the greater proportion of cases Very frequently (perhaps generally) if the constitutional element be recognized at all, it is dubbed "scrofula" or "rickets!" Old Proteus masquerading under a respectable name, but none the less susceptible to the eloquent persuasion of our reliable friends, mercury and iodine I venture to say that in quite a proportion of troublesome cases of dental caries and irregularities in children, constitutional treatment of this kind will prove a very useful auxiliary to the efforts of the dentist

In the consideration of this important question, there are several facts to be borne in mind by the dental surgeon These may be formulated as follows 1st The great frequency of syphilis, even in refined society 2d The recklessness as to the consequences of matrimony exhibited by the average syphilitic patient 3d The great percentage of danger of hereditary transmission of even remote syphilitic taint 4th The large number of tainted children that he must necessarily be called upon to treat as a consequence of the foregoing propositions 5th That Hutchinson's test teeth and facies syphilitica are by no means a *sine qua non* in hereditary syphilis It may be readily observed that the duty of the dental surgeon is not completed with the local treatment of such cases as those under consideration, but he should recommend a suitable course of constitutional treatment The time is coming when every dentist may not only recommend, but will be competent to carry out, such a course in detail

The co relation of so called struma and hereditary syphilis has of late years come to be suspected, and the tendency in certain quarters to regard many cases of alleged scrofulous lesions as remote manifestations of syphilitic taint, is rapidly gaining ground This, indeed, was tacitly admitted years ago by Astley Cooper, whose favorite remedy for scrofula consisted of the bichloride of mercury, in Huxham's tincture of cinchona bark

In connection with the subject of hereditary syphilis, it is well to remember that there is such a thing as late hereditary syphilis, in which, while the patient escapes all manifestations of the disease during childhood, save perhaps malformed or crumbling teeth, lesions of the mouth, jaws, and nasal cavities appear later in life Ziessl has collected over one hundred of such cases, and has reported a number observed by himself These cases strongly resemble tertiary acquired syphilis, and appear, as a rule, about the period of adolescence Osseous and nervous lesions of a severe character usually predominate, the osseous lesions having a special predilection for the nasal and palatal bones I recall a case of caries of the skull of this character

It may be remarked in passing that many cases of ozæna, or fetid nasal catarrh, with resulting necrosis or caries of bone or cartilage, are attributed to simple catarrhal inflammation, the diagnosis being based mainly upon the absence of specific history or typical lesions Most of the cases are the result of acquired syphilis, but some of them undoubtedly are late manifestations of hereditary taint As far as my personal opinion is concerned, I have been unable to convince myself that simple catarrh is ever the cause of nasal or palatal necrosis or caries I recall two cases in which failure to accept this view on the part of the family physician, resulted in serious and irreparable disfigurement To apply this to dental and oral practice, it is only necessary to remember that necrosis, or caries of the palate or jaws, accompanied by or dependent upon, alleged fetid nasal catarrh or ozæna, can, with almost absolute safety, be pronounced syphilitic It must be borne in mind, however, that such lesions may represent the errors or misfortunes of a past generation, and may therefore cast no discredit upon the respectability of the patient

The primary lesion of acquired syphilis very rarely occurs within the mouth, chancre of the lip being more frequent The dental surgeon will therefore seldom meet with it I have already alluded to a case in which infection by dental instruments was the presumable origin of the disease Unfortunately, I did not have an opportunity to observe the case from its inception At the time I first examined the patient, secondary sore throat and mucous patches had already appeared A small sluggish indurated ulcer existed upon the gums, below the lower middle incisors The glands beneath the jaw were the first and only glandular changes to attract the attention of the patient, and they were disproportionally enlarged as compared with the rest of the glandular system It was claimed by the patient that the sore upon the gums appeared about three weeks after having had her teeth cleaned and put in order The "kernels," as she termed them, beneath the jaw, appeared about a week or ten days later There were no evidences of venereal infection, and as far as physical appearances went she had never been exposed to venereal contagion

I recall another case of interest in which the primary lesion appeared upon the tip of the tongue There was very little induration about the sore, which appeared as a shallow ulcer the size of a split pea, with a grayish base covered with an exudate very like a diphtheritic membrane The glands under the jaw enlarged, and the case ran the ordinary course of syphilis The source of infection was traced, and I found mucous patches in the mouth of the woman from whom the disease was contracted She herself gave a clear history of having contracted her syphilis from her husband In this case, a diagnosis could have been made in no other way than by tracing the source of infection, and by observation of the subsequent course of the case, inasmuch as the primary lesion was decidedly atypical

The oral symptoms of the secondary or active period of acquired syphilis are of the most vital importance to the dental surgeon, by virtue of 1st, their contagiousness, 2d, their liability to be mistaken for innocuous lesions, 3d, the prolonged period during which they are apt to develop at any time, and often without the patient's knowledge, 4th, the necessity for nearly all syphilitics to consult their dentist sooner or later, during the active period of syphilis The later, or so called tertiary lesions, are so destructive that they usually announce their presence at once, and more important still, they are probably rarely contagious

The lesions of the mouth occurring during the course of constitutional syphilis, may be briefly classified as 1st Excoriations or erosions, and rhagades, or fissures, occurring with or without more or less generalized inflammation of mucous membrane 2d Mucous patches and tubercles 3d Early ulcerations, superficial or deep 4th Late ulcerations, superficial or deep 5th Early and late bone and periosteal lesions

Excoriations or erosions and fissures are the most dangerous to the safety of healthy persons, from the fact that they are often precisely identical in their physical characters with similar lesions from simple causes Their secretion, however, is extremely contagious, and the act of kissing may be followed by disastrous results Fortunately, these lesions are usually quite irritable, occurring, as they generally do, in smokers, and they consequently usually announce their presence most emphatically These lesions may appear at any time during the course of syphilis, but are most often seen during the first year They are due to the co existence of local irritation with constitutional depravity, and as both of these conditions occur from simple causes, it is obvious that great caution is necessary in the matter of diagnosis

These erosions and fissures are distinguished in most cases by the generally reddened and tender state of the mucous membrane Unlike other syphilitic lesions, they are sometimes extremely painful, the suffering being greatly disproportionate to the actual lesion present A diagnosis of syphilis is not warranted in these lesions unless confirmed by more positive indications than those afforded by the lesions themselves

The typical mucous patch is the most frequent of the oral lesions of syphilis It represents a papule upon a mucous surface, and also represents the foundation of most of the ulcerative lesions of the disease, *i e*, a localized proliferation of cells It is a true hyperplasia of tissue, and this is an important element in the diagnosis The patch is elevated, of a grayish or yellowish color, and varies in size from a scarcely perceptible point to a patch or collection of patches the size of a silver quarter, rarely larger There is no inflammatory area about it as a rule, but if irritated, the ordinary characters of inflamed mucous membrane will be presented.

There is a peculiar form of mucous patch which is sometimes seen about the borders of the tongue, that merits special description It is the most obstinate of the lesions of the tongue, excepting, perhaps, the rare form known as syphilitic psoriasis of the tongue It appears in the form of a furrow or cleft in the border of the organ upon one or both sides This furrow has an appearance resembling a puckering in or involution of the mucous membrane The borders of the lesion are rounded, and covered with a fibrous layer of cloudy epithelium, which looks very much like a thin film of coagulated albumen

The mucous tubercle is an exaggerated mucous patch, and consists of a similar but more extensive aggregation of cells Either the patch or the tubercle may go on to ulceration

There is a peculiar tendency in some cases of mucous patches to a circinate arrangement very like ordinary ringworm of the skin in form This is due to a coalescence of circular patches, and is especially marked upon the roof of the mouth, involving both the hard palate and velum When this circinate eruption is seen in the mouth, nothing more is wanted to complete the diagnosis of syphilis, although corroborative evidence should always be sought for

The special points which are to be sought for in the diagnosis of syphilis will serve in all cases, save in late syphilis, where we may be compelled to depend upon the history and the appearance of the lesions alone

These evidences are, First, A diffuse passive congestion or hyperæmia of the fauces and pharynx, without corresponding pain in deglutition Should the patient have a bad cold at the time, this sign ceases to be of great value Second, Alopecia or falling of the hair, in the absence of parasitic disease Third, Coppery spots or cicatrices, the remnants of faded skin lesions Fourth, The presence of scabby spots or pimples on the scalp Fifth, Enlargement of the lymphatic glands, those of the neck being especially accessible Enlargement of the sub occipital glands is pathognomonic Sixth, A possible history of bone pains and aches, worse at night, this sign being more important in late syphilis Seventh, The presence of circumscribed periosteal swellings or nodes

It will be observed that most of these signs can be sought for and often found by the dentist, without examination of any other regions than the oral cavity, pharynx, head and neck Indeed, a quite thorough examination may often be made, without exciting suspicion, if such a course be politic For obvious reasons, I do not include some diagnostic points for which the general surgeon would seek An innocent and to all appearances quite casual search for evidences of such diseases as scrofula, rheumatism and catarrh may develop some startling and valuable results in dental and oral practice When the patient is sufficiently cosmopolitan or candid, the history of infection will clear up any possible obscurity A useful point in the diagnosis is that the patient is usually distressingly healthy aside from the local manifestations of disease, and even these may be treated with great indifference

There is a peculiar lesion of the tongue to which allusion has already been made, that merits special attention, although it must be confessed it is a lesion that is rarely seen I refer to syphilitic lingual "psoriasis" It closely resembles simple psoriasis of the tongue, and is apt to make its appearance late in the course of the disease, when nothing but the history of the case remains to assist in the diagnosis It consists of a thin whitish pellicle, due to thickened epithelium, the mucous membrane beneath having a peculiar scalded appearance Quite often, the tongue presents large irregular patches of scalded looking mucous membrane The borders of the tongue are most apt to be affected That these lesions are dangerous, is shown by a case reported by Fournier in which a patient with this lesion infected a healthy woman by kissing, five years after he contracted the disease It is the most obstinate of lesions, and will persist after all other evidences of syphilis have yielded to treatment I have a case at the present time that is absolutely intractable to therapeutic measures

There is a form of ulceration of the mucous membrane which occurs in debilitated states of the system, and is popularly known as "canker" It is met with especial frequency in nursing women This is important, in view of the fact that it may be mistaken for syphilis, and *vice versa* These erosions or ulcerations are superficial in character, usually multiple, and appear in successive crops They are very difficult of cure sometimes, and require a treatment which is the direct antithesis of that required for syphilis The eruption is probably a herpes, the basis of which is a neurosis, and in its treatment nervine tonics are indicated

These lesions are preceded by simple hyperæmia, with little or no swelling and evidently no new formation Their color is usually pearly white, or, if greatly inflamed, they present a yellowish base They look very much as if the mucous membrane had been snipped out with scissors They are often quite painful There are no evidences of constitutional taint in the form of glandular engorgement, excepting in some strumous cases, in whom a diagnosis may be entirely dependent upon the crucial test of treatment Under mercury and iodine, these simple cases will get worse A complete change of air and scene may be necessary for their cure It is not well to be hasty in the matter of diagnosis, but it is indeed a safe rule that, to the surgeon, no one should be above suspicion

Some of the very late lesions of the mouth in syphilitic subjects are very difficult of diagnosis, the history alone being all that we can depend upon These lesions are slight erosions and exudations, and, as a rule, are not contagious Oftentimes, perhaps they are not really syphilitic, and depend upon, first, exhaustion and malnutrition produced by the previous general infection, second, mercury in too free doses Most often, both of these causes are contributing factors It should be remembered that because a patient has once had syphilis is no reason that he should not thereafter have simple and respectable lesions of the oral cavity The excessive use of mercury, or even its moderate use, in special cases of idiosyncrasy, may produce lesions of the greatest importance to the oral surgeon Much uncalled for abuse has been heaped upon this valuable drug, but after all, it is sometimes responsible for morbid changes, especially in the mouth It is debilitating in large doses, and as eliminated by the salivary glands, it is apt to be irritating I see many cases of supposed mucous patches and syphilitic ulcerations which I am inclined to attribute to mercury When, therefore, I find that the mouth not only does not improve, but really grows worse, under mercury, I infer that the trouble is really due to the drug, and substitute iron and tonics The horribly fetid odor of the breath, due to decomposing fat, and the sponginess and tenderness of the gums, will indicate the probable cause in these cases, for lesions due to syphilis *per se* rarely fail to improve under mercury, when carried to its full physiological effects It is certainly a suggestive fact that mercury is capable of preventing skin lesions in a large proportion of cases of syphilis, but does not seem to completely prevent oral manifestations in the majority of cases While not yet prepared to formulate a rule, I am free to say, that the patients whose mouths have given me the most trouble, have been those to whom mercury has been given most freely

It has been noted by dental surgeons that mercury is capable of inducing the condition known as pyorrhœa alveolaris From personal observation I am convinced of the correctness of this view There is also little doubt in my mind as to the probability of syphilis itself being the cause in some cases Although not familiar with dental literature upon this subject, I have found in conversation with several members of the dental profession, that cases occasionally occur which are attributed to syphilis It is obvious that in these cases, constitutional treatment is of the greatest importance, and is the only method of accomplishing that basic principle of all treatment —removal of the cause

Although the ordinary erosions, mucous patches, and ulcerations of the oral cavity occurring during the secondary period, are annoying, they are rarely destructive This cannot be said of the late secondary and tertiary lesions A characteristic feature of late syphilis is a tendency to the deposit of so-called gummy material or syphiloma in various situations This consists essentially of an accumulation of cells of a low grade, which obstruct the tissues, and impair their vitality

This deposit has a special predilection for the osseous tissues and periosteum, and often affects the jaws and hard palate, with or without involvement of the nasal bones Its results are inflammation, caries, or necrosis In the diagnosis we rely upon the history somewhat, but there is usually no difficulty in passing an opinion upon the physical appearances alone If seen early, a gummy tumor may be detected It is a hard inelastic swelling over the bone It is not especially tender, and is not much discolored, as a rule, although it may be of a bluish tint It is not very painful, except at night, when the pain is apt to be severe Taken all in all, the morbid process is a passive one Later on, the gumma softens at its centre, and the skin becomes thinned and discolored Ulceration may occur, or under treatment the softened material may resolve If the tumor absorbs, a depression remains in the surface of the bone If ulceration occurs, the probe will usually strike bare and roughened bone at the bottom of the cavity When small bones, such as the vomer and palate, are involved, nutrition is so impaired that necrosis occurs in many cases In such cases the bone is apt to come away entire and preserve its natural form Nothing but syphilis will thus dissect out a bone The resulting deformity in these cases is very marked, and should the palate be involved, speech is so impaired that the aid of the dentist is necessary With an obturator, these cases of acquired cleft palate may be made quite comfortable Operation is rarely productive of great benefit, on account of the low vitality of the tissues in long standing cases of syphilis

It is probable that, with the exception of phosphorus necrosis, traumatic necrosis, and cases undoubtedly due to diseased conditions of the teeth, the majority of cases of necrosis of the jaws, nose and palate are due to syphilis, more or less remote The dental engine has done excellent service in these cases In the hands of Dr Goodwillie, especially, it has done good work It has been shown that by early operation the necrosis may be limited and recovery hastened

I have already encroached upon the time of the Section to a considerable extent, yet I have not been able to do more than outline in a general way the more important points of my subject I am well aware that the ground has not been thoroughly covered, but if points in the individual experiences of the members have been recalled to mind, the object of this paper will have been accomplished

125 State St, Chicago

MEDICAL PROGRESS

Scarlet Fever from Cows Milk —At a meeting of the Epidemiological Society, on April 14, Dr James Cameron read a paper entitled, "Observations on a certain Malady occurring among Cows at a time when the Milk produced by them disseminated Scarlet Fever," of which the following is an abstract The author began by stating that he proposed to lay before the Society a short description of a cow disease which had been the subject of investigation by Mr W H Power, Dr Klein, and himself during a recent inquiry into an outbreak of scarlet fever which occurred in certain districts in London and in Hendon amongst consumers of milk derived from a dairy farm situated within his sanitary district It was not his intention to discuss the circumstantial evidence which led to the discovery of this disease amongst the cows, or which proved its connection with the milk These were respectively in the hands of Mr Power and Dr Klein The disease is certainly not a new one, it has been known to some farmers and cowkeepers, at any rate, as a catching malady under the designation of sore teats, blistered teats, and the like, but it has never hitherto been recognized or described as a specific contagious disease amongst cows, or considered to have any concern with the causation of scarlet fever in the human subject, and has commonly been regarded as a malady of little importance After giving an account of the farm, and speaking favorably of its sanitary condition, the author stated that the disease first appeared in some newly purchased cows, which had arrived about a fortnight before the first cases of scarlet fever occurred among consumers of the milk It was subsequently ascertained that one of these cows, which was the first sufferer, introduced the disease into the herd, the malady spreading from shed to shed until the whole herd of 100 cows, with very few exceptions, was attacked, while, coincidently with the spread of the disease among the cows and into the various sheds, scarlet fever made its appearance, and continued to prevail among the consumers of the milk procured from these sheds Dr Cameron described the disease generally as a specific contagious disease, occurring usually in the first instance amongst newly calved cows, and capable of being communicated to healthy cows by direct inoculation of the teats with virus conveyed by the hands of the cowman The disease may continue from four to six weeks, and is characterized by general constitutional disturbance, a short initiatory fever, a dry hacking cough, sometimes quickened breathing, sore throat in severe cases, discharges from the nostrils and eyes, an eruption on the skin round the eyes and hind quarters, vesicles on the teats and udder, alteration in the quality of the milk secretion, and well marked visceral lesions The author then proceeded to discuss the symptoms in detail, and referring to the eruption on the teats and udder, stated that from five to seven days after the commencement of the illness one or more teats became much swollen, and vesicles or bullæ shortly make their appearance upon them These vesicles are usually rubbed and broken in milking, leaving sores with raised ulcerated looking edges; at this period the disease appears to be easily conveyed to other cows. Shortly after the vesicle has been broken a brown scab forms upon the sore, and this may remain from ten days or a fortnight to five or six weeks, a thin discharge escaping from beneath it until the sore is healed. There is a tendency for the milk to become ropy during the illness, but this is not always present, and as a rule this condition is not apparent until the milk has stood for five or six hours; hence the milk from this farm was distributed before this peculiarity had had time to show itself. After describing the difference between cow-pox and the disease in question, Dr. Cameron urged the necessity for examination of cows and for the removal of all suspected animals from the milk business, and he expressed the hope that the Government would see fit before long to institute some means of more effectually protecting the general public against the recurrence of these disastrous outbreaks of disease which are due to milk.—*Lancet*, May 15, 1886.

DELIRIUM TREMENS CAUSED BY CHEWING TEA.—DR. W. B. SLAYTER, of Halifax, N. S., relates a peculiar and interesting case of this nature. A girl complained of sleeplesness, nervousness, and repeated twitchings of the muscles of the face and extremities, which would continue for several minutes at a time. These symptoms had been present for several months previously. Her mistress informed me that the girl had been acting strangely for several days. She was wandering in her mind at times, and imagined people and evil spirits were about her seeking to do her harm. She had not slept for several nights, and on one or two occasions had been found at night wandering about the house. Pulse 96 and small; tongue dry and brown; eyes suffused; irregular action of the heart-weight at præcordia; sallow complexion. A dose of bromide of potassium and hydrate of chloral gave her a good rest for the night, and next morning she was sent home to her mother.

At 4.30 A. M. three days later I was again summoned to see her. Some men had found her walking about one of the wharves of our city, in the neighborhood of her mother's house. They tried to persuade her to go home, but she broke away from them and endeavored to jump off the end of the wharf, when she was caught and taken to her home. I found her with a pulse of 110°, a very dry and brown tongue, suffused eyes, no marked increase of temperature, violent delirium, and tremulous hands and arms—in short, the well marked symptoms of delirium tremens. Her mother informed me that she had complained of a good deal of pain in the abdomen, and on examination I found a smooth, quite hard tumor in the right iliac region, half as large again as an ordinary orange. Owing to the violent delirium I was unable to find out whether it was tender to the touch or not. A hypodermic injection of morphia somewhat relieved the nervous symptoms. A brisk cathartic brought away a mass of hardened fæces, followed by a large quantity of a thickish tarry-looking excreta, which seemed to be made up of tea-leaves in different stages of maceration, quite a large proportion, probably a third, being tea leaves quite unchanged in appearance or color. Bromide of potassium and chloral in a few days quieted the nerve centres; good nursing, proper diet, and tonics soon restored the patient to her usual health. After the action of the cathartic I found the abdominal swelling somewhat lessened in size, but it was not until several doses at intervals had been administered that the tumour entirely disappeared. After each dose a quantity of tea leaves were expelled. In about three weeks the evacuations were normal in appearance, and her general health was fairly restored. The patient informed me than when about 17 years of age she went to one of the New England towns to work in a factory, and there contracted the habit of chewing tea—a habit, quite common amongst the factory girls. She thought she chewed on an average about half a pound of tea daily, and some days more. It made her feel better able to work. Of course, as to quantity her estimate may not be depended on. She had never been addicted to alcoholism, and ascribed her attacks solely to the tea chewing. She tried to give it up, but felt so nervous and fidgety as to be compelled to return to the old habit. The second attack caused me to copy from my case-book the notes taken at the time. The only points of importance are the *cause* and the *repeated and continuous muscular twitchings*. Of course most physicians have met with many cases of great nervousness and fidgetiness occasioned by excessive tea drinking, but I cannot find any record in any of the works on medicine or materia medica within my reach of such severe symptoms being induced by tea chewing. Ringer tells us that "the Physiological Committee presided over by the late Dr. Hughes Bennett concluded that the *motor nerves are unaffected*." The long continued repeated muscular twitchings would seem to contradict this portion of the Committee's report.—*Lancet*, April 24, 1886.

KRULL'S METHOD OF TREATING CATARRHAL JAUNDICE.—M. R. LONGUET gives an account of this treatment and of Lowenthal's confirmation of its efficacy. It seems that Krull published an account of his method in 1877, but that it excited little attention until Lowenthal took it up. It consists simply in the administration of enemata of cold water; the first injection, of one or two quarts, at a temperature of 59° F., is thrown in gently and retained as long as possible; on the succeeding days an enema is given every morning, the temperature being gradually increased to 71.6° F., which is not exceeded. The cure is generally accomplished by the fourth day, and in no instance have more than seven injections been found necessary. No failures are mentioned, although several of the cases were of long-standing and had resisted the most varied treatment, including the use of that *ultima ratio* of the Germans Carlsbad water. No medicine is allowed to be taken, and the diet is restricted to vegetables. Lowenthal, who used injections somewhat colder than those mentioned, tried the method in forty one cases, and he absolutely confirms Krull's report of its efficiency.—*New York Medical Journal*, May 1, 1886.

THE BLOOD PLAQUE AND COAGULATION

The two most notable papers that have appeared for some time on the physiology of the blood are the "Cartwright Lectures," by Professor William Osler, on "Certain Problems in the Physiology of the Blood corpuscles," and a paper by Mr Geo T Kemp, Fellow of Johns Hopkins University, "On the so called 'New Element' of the Blood and its Relation to Coagulation," published in *Studies from the Biological Laboratory*, Vol III, No 6 Dr Osler's first lecture deals exclusively with the blood-plaque, while in his third he treats of the relation of the corpuscles to coagulation

As is well known, the blood-plaques have been variously designated as elementary corpuscles, globulins, granular *debris* or Schultze's granular masses, hæmatoblasts, and Bluttplattchen (by Bizzozero) In preference to the literal translation of Bizzozero's term, blood-plate, both Osler and Kemp have adopted the term blood-plaque as being more euphonious Various writers have referred to this element as the "third corpuscle," but the objections to this term are so grave that it has been practically abandoned The plaques may be described as minute elements circulating in the blood plasma with the other corpuscles, and possessing such specific and distinct characteristics that they must be numbered among the normal histological constituents of the blood Dr Osler gives their size as from one-sixth to one half that of a red corpuscle, which is sufficiently accurate for elements showing such variations in size Sometimes, however, a plaque may be found which measures as much as 5 mm It is a circular disc, with a smooth, well defined margin, and occasionally some are found which show a bilateral depression "It is a homogeneous, smooth, structureless protoplasm, of a light grey color, and in the unaltered state no nucleus can be found" As to whether a nucleus is found after staining there is considerable dispute After the blood has been withdrawn from the vessels two peculiarities of the plaques occasion a serious hindrance to their recognition as special elements of the blood the rapidity with which the protoplasms alter, and their tendency to adhere to one another and to substances with which they come in contact So long as they are kept in the vessels they do not seem to change more rapidly than the corpuscles, as Osler has found them unaltered in the pial vessels of man some hours after death, and well preserved plaques may be found enclosed in fibrin taken from the body some time after death

What is the origin of the plaque? More than half a dozen answers have been given to this question, and experimental evidence has been adduced in support of each answer So long as the red and white corpuscles were the only recognized histological elements of the blood it was most natural for any observer to connect the plaques and masses with one of these elements They have been variously regarded as hæmatoblasts, or young red corpuscles, as derived from the red corpuscles, as derived from the white corpuscles, as nuclei floating free in the blood, as fibrin, and finally as independent elements It seems scarcely worth the while to mention the evidence upon which these views have been founded Suffice it to say that the views are carefully examined by Kemp, and sufficient evidence brought against them (save those which claim that they are hæmatoblasts or independent elements) to render them most improbable That they are not due to changes produced in other elements after the blood is drawn is shown by pricking the finger through a drop of osmic acid, by which process all the elements of the blood are immediately set when they leave the vessel Furthermore, we could scarcely ask for more conclusive proof than that five competent observers—Bizzozero, Lavdovsky, Hlava, Schimmelbusch and Osler—have seen them circulating in the vessels of the mesentery, and in the uninjured vessels of the connective tissue of young rats Kemp's opinion is that there is no doubt that the plaques exist in the blood, and we have not yet sufficient evidence to believe them to be other than an independent morphological element—a view which is held by Max Schultze, Osler, Bizozzero, Laker, Lavdovsky, Halla and Schimmelbusch

Careful and painstaking enumerations as to the presence of the plaques in the various acute and chronic diseases have not been made, but Osler draws the following conclusions from numerous observations 1 The plaques are increased in all chronic wasting diseases—cachexiæ—with or without fever, debilitated persons, the subjects of phthisis, cancer or other chronic wasting diseases present a marked increase In phthisis the ratio of the plaques to the red corpuscles may be as high as 1 to 5 2 In acute sthenic fevers they are not increased in the early stages As the disease advances, however, and the patient becomes weaker and more debilitated the increase is marked as a rule This is especially well seen in typhoid fever, in which during the first week the number of plaques may not rise above normal, while in the third and fourth weeks there is usually a large increase 3 In the so-called blood diseases the number of the plaques is variable For example, many observers have noticed large numbers in certain cases of leukæmia, but in other cases the increase is not apparent, and the same is true of lymphatic anæmia In some cases of Hodgkin's disease Dr Osler has seen the plaques in very large numbers, they may be scanty in profound anæmia, and in cases of pernicious anæmia the clusters of plaques may be almost absent, or much more scanty than in health

It must be acknowledged that the theory of Hayem, that the plaques are hæmatoblasts, is strongly supported He believes that the red discs are nucleated, and in an article in the *Archives de Physiologie* three years ago he asserted with confidence that the plaques are nucleated If, as Hayem asserts, the plaques are biconcova, this is another point of resemblance Laker agrees with Hayem on this point, but Bizzozero and Schimmelbush assert that they only become biconcova when drawn into a salt solution or Hayem's fluid Kemp, however, asserts that in addition to seeing them on edge and making out their characteristic dumb-bell shape, he has succeeded several times in seeing them roll over and over in a very slow current, so that at least in *osmic acid* and Hayem's solution he was able to convince himself beyond all question of their biconcavity The biconcavity is also shown in a photograph made from a specimen stained with Bismarck brown Afanasef regards Hayem's "nucleus" as only a precipitation of granules in the centre of the plaque, and Schimmelbusch takes a similar ground Kemp has failed to see anything which he regards as a nucleus, and thinks that the concavity seen when examining full on the surface may be very probably mistaken for a nucleus As in the case of the red corpuscles, the question of a cell membrane may be raised in regard to the plaques

Still another point of resemblance between the red corpuscles and plaques is that, under certain circumstances the latter will shrivel and become crenate, and Kemp says that it is quite a usual thing to see both plaques and red corpuscles caught at one end and drawn out by a current so as to present a long, pear shaped or even threadlike appearance According to Hayem, again, the plaques contain hæmoglobin, a view which is supported by Mayet and Laptschinsky, the latter having described corpuscles about one third the size of the red corpuscles, which are sometimes more strongly colored than usual, and sometimes colorless Riess, Bizzozero, Laker, Hlava, Halla and Schimmelbusch take the view that the plaques are without color, and Kemp has tried in vain to find hæmoglobin in them, even with the double staining fluid of carmine and indigo carmine, which is claimed to stain green any cell containing hæmoglobin Another point of relation between the plaques and red corpuscles, pointed out by Hayem, Bizzozero and Lavdovsky, is that in different animals the size of the plaques always varies in the same ratio as that of the red corpuscles To this point Kemp adds that in trying to get a preparation from which to make a photograph of the plaques, he tried ten different staining fluids on the blood after hardening in osmic acid, and *in every case* the plaques and red discs stained proportionately

Hayem further supports his hæmatoblast theory by the assertion that in pathological conditions of the system where "new blood" is demanded, we may always find the plaques in increased numbers—which fact had already been stated by Reiss But there is an objection to this assertion which is so great as almost to necessitate a Scotch verdict Kemp says "The sources of error in all numerical determinations of the plaques are very great, on account of the tendency which these elements have to adhere to each other or to any foreign body with which they come in contact I was early led to see that for this reason numerical determinations, where the blood had to be measured, were practically of little value The same point has been made by Schimmelbusch, who, in addition to the results of his own observations, has shown that enormous variations exist in the results of the same observer, while different observers have shown diametrically opposite results, in determining the number of plaques in certain pathological conditions I think the only way to obtain a reliable numerical determination of the plaques would be to prick the skin through a drop of osmic acid, examine a thin layer of this mixture, and count the relative number of plaques and red corpuscles A separate determination would then have to be made by the usual methods for the red corpuscles, from which the number of plaques could be calculated Even this method would not be free from error, for Hayem has shown that enough plaques adhere to the edges of the wound to make an appreciable difference in the extravasated blood Probably the most suggestive observations in support of the hæmatoblast theory were made by Hayem, who has found the plaques in the vaso formative cells of the mesentery of newly-born kittens, where the young red blood corpuscles are in process of development, while both Hayem and Pouchet have described intermediate stages between the plaques and the red corpuscles[1] We cannot regard the hæmatoblast theory as proved, but we must acknowledge that the relationships between the plaques and the red corpuscles are most striking, and it seems as though this is the most plausible explanation offered "

We have now come to the question as to the relation of the plaques to coagulation, which will be discussed in the next issue of THE JOURNAL

THE AMERICAN MEDICAL ASSOCIATION

The *Medical Record*, of New York, and a few other journals of less note have been indulging in expressions calculated to create the impression that the recent meeting of the Association was less representative of the whole profession than most of its predecessors, and that the action of its Judicial Council in reference to the admission of the delegates from the Philadelphia County Medical Society had started a serious split in the membership of the Association To the latter accusation the *Medical and Surgical Reporter*, of Philadelphia, of May 22, replies so directly and truthfully that we quote from it as follows

" It is hardly fair to speak of a split when only a few fibres are carried away, it would be more correct to say a shave or a scrape The main body of the American Medical Association is to day more united than it ever was, and it has lost the allegiance only of those who 'got mad' because they could not control We cannot help but see that the action of the Judicial Council was eminently proper in the case of the alleged delegation from the Philadelphia County Medical Society There were two sets of delegates before them, one set had been regularly and legally nominated, but they were not elected, the other set had been elected, but, and this is a big BUT, they had not been legally nominated, and as such nomination is, according to the constitution and by-laws of the Society, a *sine qua non* of a legal election, every unbiased mind must hold that they were not legally elected Hence, the clear position was that the Philadelphia County Medical Society had no legally accredited delegates, and the Society was not entitled to recognition "

The pretense that the recent meeting at St Louis was in any sense more geographical or less generally representative than in former years is very easily disproved by reference to the facts Probably no three meetings could be chosen from the whole history of the Association affording a fairer basis for comparison than those held in New York, 1880, Washington, 1884, and St Louis, 1886 The first was in the great metropolis of the Atlantic States, immediately surrounded by the greatest density of population and the most complete social organization of the profession, the second in the capital of the country, with more local attractions than any other city, and the third in a great city in the central part of the Mississippi Valley The number of members attending each of these meetings was between 1,000 and 1,200, embracing delegates from almost every State and Territory in the Union

The six States that furnished the largest number of members in the meeting at New York in 1880, were New York, Pennsylvania, Massachusetts, New Jersey, Michigan and Connecticut, New York alone furnishing 319, or very nearly one third of the whole number present

The six States having the highest number of members in the meeting at Washington, 1884, were Pennsylvania, Ohio, New York, Indiana, Illinois, and Iowa, Pennsylvania sending the highest number, it being 219

The six States having the highest number of members in the meeting in St Louis in 1886, were Missouri, Illinois, Iowa, Indiana, Pennsylvania, and Ohio, Missouri furnishing 252, or less than one-quarter of the whole number in attendance The only States not represented in the meeting at St Louis were New Hampshire in the northeast, Delaware in the middle Atlantic region, Alabama in the south or Gulf region, and Nevada and Oregon in the extreme west These facts show the entire fallacy of claiming that the recent meeting was less representative of the profession of the whole country than those held at any former period If such a claim could be made in reference to either of the three meetings we have named, it would be the one held in New York in 1880, where a much larger proportion of members belonged to the State in which the meeting was held, than in either of the others Again, in 1880 the regular paying membership of the Association was less than 2,000, while it is now double that number, and is composed of representatives from the State, County and other local medical societies in every State, aggregating between 30,000 and 40,000 of the most active, enterprising members of the profession of the United States These facts do not afford much support to the idea that the Association is about to crumble to pieces, or be speedily succeeded by a "Congress of American Specialists" constructed from a union or confederation of half a dozen American specialist organizations whose entire aggregate membership will hardly number five hundred

---

[1] The observation of Hlava may also be taken in support of Hayem and Pouchet the colored bodies which he distinguishes from the plaques being plaques containing hæmoglobin and on the way to form red corpuscles

MAY INJURIES BE EXHIBITED TO JURIES?

The practice of exhibiting injured or deformed limbs to juries in malpractice suits by a plaintiff, or by the defendant in suits for medical fees for services, has long been regarded as a fruitful source of erroneous verdicts, and an act of manifest unfairness to the physician or surgeon To allow a jury of twelve, or twelve hundred, uneducated (medically) and unskilled men to say in how far the surgeon is responsible for a given deformity is as manifestly unfair as to allow the same jury to dictate to the attending physician as to what remedies should be used in a case of diabetes or typhoid fever, whether the forceps should be used in a case of shoulder presentation, or whether any, and what, antiseptic agent should be used in a case of ovariotomy

The case of Carstens *vs* Hauselman, decided by the Supreme Court of Michigan, on May 12, has some points of interest to surgeons as regards this question Action was brought by the surgeon for services rendered in the case and treatment of a fracture of the leg Among other points of defense one was raised of improper treatment The lower Court gave verdict and judgment for the plaintiff Error was assigned because the Court below had refused to allow the defendant to exhibit her injured leg to the jury Upon error the Supreme Court, *per* Campbell, J, used the following language

"The injury occurred several years before, and there was testimony concerning the correctness of the treatment, which necessarily involved medical questions which no jury could be supposed to fully comprehend It is not competent to allow juries to determine for themselves whether a physician's course has been proper or improper in the treatment of a fractured limb, and the Court very properly refused to permit them to inspect it for that purpose No inspection after an injury is healed, apart from some knowledge of the character of the injury and the methods of treatment, could enable even a medical expert to decide upon the merits or demerits of the attending surgeon A jury's guessing from such an inspection would be of no value whatever, and any needless exposure would have been, as the Court below properly held, improper, if not indecent"

SOCIETY PROCEEDINGS

AMERICAN LARYNGOLOGICAL ASSOCIATION

Eighth Annual Meeting, held in the Hall of the College of Physicians, of Philadelphia, May 27, 28 and 29, 1886

THE PRESIDENT, DR HARRISON ALLEN, of Philadelphia, delivered the *Annual Address*.

Following the Presidential address, a letter from the Secretary of the Philadelphia College of Physicians, tendering to the Association the use of the hall and the hospitalities of the college, was read

DR HARRISON ALLEN then read a paper entitled

TWO CASES OF ADENOID DISEASE OF THE ROOF OF THE PHARYNX WHICH EXHIBITED UNUSUAL FEATURES

The result of operations for the removal of adenoid tissue from the pharynx is usually so excellent that the necessity for a repetition of the operation is said to be seldom met with The following cases were related as presenting certain points of interest

Case I—A B, age 5 years, much emaciated, without appetite, suffering with frequent attacks of indigestion, was sent to him in the latter part of January, 1884 Examination showed the roof of the mouth to be elevated, but the slightest attempt to depress the tongue was followed by gagging The nostrils were filled with a mucoid discharge, and a small quantity of a similar discharge was seen in the fauces after gagging During the day, the respiration was not exceedingly difficult, but at night it was greatly impeded Almost directly after the child fell asleep, respiration became labored After three or four inhalations, breathing would cease, the child would open its mouth and make strenuous efforts to inspire The child would then awaken and a forced inspiration ensue It would then quickly fall asleep and the same phenomena would recur, and in this manner the entire night would be passed To these were occasionally added fits of crying and emesis During an attack of whooping-cough the symptoms became much exaggerated, and were associated with irregular action of the heart

Hypertrophy of the adenoid tissue of the pharynx with unusual reflex phenomena was diagnosed On January 29, with the patient under ether, the operation for the removal of this tissue was performed An attempt was made to break down this tissue with the finger, but the presence of the finger arrested respiration Efforts were then made to rasp the growth away with an instrument passed through the nose, but in a short time the patient showed symptoms of depression and the operation was suspended The pharynx was next seared with the hot wire During the succeeding five weeks, applications of iodine and glycerine were made, but there was no evident improvement in the breathing at night The patient was again etherized and the pharynx shown to be empty Suspecting that the tonsils might be the cause of the difficulty, a portion of each was excised Still no improvement followed A third attempt to detect the cause of the difficulty was made, and it was determined positively that the nostrils were patulous A careful examination showed that during sleep the tongue fell backwards, and that this was the essential condition It was then directed that when these attacks came on the boy should be held with the face downwards The moment this position was assumed the child passed into a profound slumber It was then so arranged that during the entire night the patient should be watched, so that the tongue should not have an opportunity of falling back This watching has been continued up to the present time The boy prefers to lie upon his side, but when the attacks come on, turns on his face without awakening He is now a strong and healthy boy

Case 2 —A girl 6 years of age The child was cyanotic at birth The extremities were cold and of a bluish color, but no difficulty with the heart could be detected The irritability of the pharynx was excessive The patient had been twice operated on by other surgeons, and it was inferred that an attempt had been made to remove morbid tissue The patient was etherized with great care and the entire nasal pharynx found to be much smaller than normal, and its roof was highly arched in form The posterior slope of the roof was the seat of adenoid growths Some were removed by the galvano cautery passed through the nose Some of the nodules at the lower border of the pharynx were removed with the scissors

The patient was improved, and two weeks later she was again etherized, and it was ascertained that all the nodules had been removed, but that the membrane at the roof of the mouth was exceedingly thick and tended to obstruct the passage of air This was subjected to cauterization in several places No further efforts were made to reduce the size of the membrane by operation, and the patient was treated as a case of perverted nutrition of the osseous system Iodine and glycerine were applied locally Under this treatment gradual improvement in the nasal respiration took place, and at the present time the child appeared to be perfectly recovered

Dr **Franklin H Hooper**, of Boston, had had only one case in which any accident followed the operation for removal of adenoid tissue This was in the case of a little girl 8 years of age, of a neurotic temperament and very precocious Nasal respiration had been obstructed and articulation had been defective since the age of 3 years Hearing was also impaired A large quantity of adenoid tissue was demonstrated, the removal of this was followed by great improvement in breathing and articulation The breathing did not improve at once, but the use of the Politzer bag resulted in marked improvement This had been previously tried without effect From this time she began to grow nervous. Eight days after the restoration of hearing, she complained that she could not keep still In a short time the symptoms of chorea developed and gradually increased in intensity The speech became affected, and for over a month she was unable to speak The chorea assumed an exceedingly severe form She was unable to sleep Various remedies were tried without benefit Finally urethran was suggested The use of this drug was followed by quiet sleep Since this time the child has continued to improve and the chorea has now entirely disappeared

Dr **E L Shurly**, of Detroit Where the galvano-cautery is used, it has been said that there is considerable danger of the ether taking fire when this is used as the anæsthetic He always uses chloroform under such circumstances

Dr **S W Langmaid**, of Detroit In one case coming under his observation there was a period of thirty-five seconds between the respirations In that case, the difficulty was relieved by the patient getting on his hands and knees There must have been either a falling back of the tongue or some inhibitory action of the respiratory centre The removal of the growth did away with the interruption of respiration. He was not aware that much has been said in regard to this interruption of respiration

Dr **Carl Seiler**, of Philadelphia One point with reference to adenoid growths in the roof of the pharynx is the effect upon singing voice Dr Bosworth, of New York, called his attention to the fact that different lines might be drawn on the roof of the pharynx corresponding to different notes of the scale A swelling in a particular situation will interfere with the production of a certain note A case illustrating this was seen by him a short time ago A young lady could not reach the upper notes of the scale He found a small adenoid growth which he removed with his finger She is now able to reach every note with the greatest ease

Dr **Harrison Allen** said that Dr Hooper's case is an evidence of the way in which the adenoid growths may affect the entire system His case is noteworthy in view of the fact that the phenomena appeared after the removal of the growth With regard to the use of ether, he has not been unaware of the danger, but by fanning the patient for a moment before using the cautery the vapor of the ether is removed, and he has experienced no difficulty He has been unable to find on record a case similar to the first one narrated Dr Langmaid's case agrees with it in that the difficulty was relieved by change of position In a case similar to the one related by Dr Seiler, he removed a small mass of adenoid tissue and although the patient was able to reach the higher notes, she complained of the sensation of a large cavity in the situation from which the mass was removed

Dr **J Solis Cohen** then presented for **Professor**

RAMON DE LA SOTA Y LASTRA, of Seville, Spain, a paper on

LUPUS OF THE THROAT

The author referred to the difficulty of diagnosis which was experienced in many of these cases, and in illustration related the following In 1884, he was consulted by a physician on account of an affection of the throat The patient was much emaciated, reduced in strength and with a clay-colored complexion He was 60 years of age The trouble with the throat had commenced one year previously He was unable to take anything but milk and broth The throat was covered with psoriatic scales The pharynx was lumpy and of a wine red color The right tonsil was the seat of an ulceration extending from the pyriform fossa below to the middle of the uvula and involving half that structure Its borders were red and swollen, its surface lumpy and irregular, and of a hard and elastic consistence Some pain was produced by palpation, but no bleeding There was no trouble while talking or on coughing Liquids were swallowed without difficulty Breathing was accomplished with perfect freedom The submaxillary glands were swollen The patient had suffered from rheumatism, but no history of syphilis could be obtained Taking into consideration the history of the case and the age of the patient, he considered it an ulcerated epithelioma This was concurred in by the patient's physicians, nevertheless, mistrusting the testimony obtained, antisyphilitic medication with mercurials was tried This occasioned such bad results that it was necessary to suspend it He was then placed upon the use of iron and bitter tonics and such diet as he could take The specific treatment was subsequently resumed, but the local lesion assumed such a bad aspect that it became necessary to give up the treatment From the fact that the ulceration was unattended by pain he began to have some doubts of its epitheliomatous nature He next prescribed sodium argenite in ascending doses, with a gargle of resorcin and the use of iodoform on the ulcerated surface after it was washed with a solution of borax For a month the ulceration continued to extend, and when he had lost all hope, it stopped its progress and became covered with healthy granulations Cicatrization went on and was complete in three months The scar is irregular, elevated and depressed, hard and soft, the posterior portion being adherent to the pharyngeal wall The lingual psoriasis continued Restoration to health has taken place It is now eighteen months since the ulcer healed With this result, he concluded that the case was one of lupus

His experience with this and other cases of lupus of the throat has led him to conclude that the disease may make its appearance at any period of life He has seen it more frequently in adults than in children, and more frequently in men than in women He has been unable to obtain any information in regard to inheritance He has not found that hard drinkers or smokers were more liable to suffer, nor has he found that great exertion of the voice or exposure to irritating substances, the application of the cautery or other agents, had any influence in its production

He has never had an opportunity of observing the initial manifestations of the disease, but he has been able to detect the involvement of sound tissues later in the disease Sometimes the mucous membrane assumes a purple color, and swells up and becomes granulated Then one or two nodules may develop and may attain the size of a pea Sometimes they become prominent without any alteration in the appearance of the mucous membrane They may remain superficial, or they may attack the mucous tissue and also the submucous tissue Their form is rounded and their surface is smooth These nodules are distinguished by their rosy red color from leprous tumors Unlike carcinoma, the tumors are usually quite distinct On pressure they present an elastic resistance This is greater than the hardness of inflammation, but less than that of epithelioma The parts on which the tumor develops become rigid and the natural movement is diminished or lost Contrary to carcinoma, which usually produces sharp lancinating pain, and to leprosy, which is generally accompanied with anæsthesia, there is in lupus no alteration of the sensitiveness of the part After a shorter or longer period, the tubercle softens and becomes ulcerated The ulceration assumes two forms In some cases the tumor becomes excavated to a considerable depth, while in others it is more superficial These ulcers do not bleed on pressure The cure is difficult and attended with the formation of scabs In some cases, these ulcers develop in a slow way, while in others they start with astonishing rapidity They may develop within a few days, or they may remain quiescent for months or years and then take on destructive action The healing of the ulcer is followed by the formation of irregular scars, raised in some places, depressed in others, red in the former, white in the latter Adhesions to different parts take place Cicatrization takes place slowly and is easily destroyed Infiltration always remains

All agree that the cure of lupus of the throat is more difficult than the same process in the skin In the cases which he has seen, the same treatment which he has employed in external lupus he has found of service in lupus of the throat He does not despise internal treatment, but uses such remedies as are indicated by the general condition of the patient This has an important influence upon the result of topical treatment If the lupus is not ulcerated he applies caustic substances Until a few months ago he used tincture of iodine He has, however, found good effects from the use of lactic acid He has used it in cases of lupus of the cheek and gums, and also of the larynx He has met with no inconvenience from its use except the pain, which varies in different cases If the lupus is ulcerated, he sometimes uses the lactic acid, more frequently he employs a wash of borax and covers the ulcer with powder of iodoform He always prescribes a gargle of a 1 per cent solution of resorcin Patients thus treated have always recovered after a greater or less time In some cases the cure has probably been realized in the natural course of the disease rather than as a result of the therapeutic measures

DR JOSEPH LEIDY, of Philadelphia, on invitation, gave

SOME POINTS CONNECTED WITH THE LARYNX AND ITS INTRINSIC MUSCLES

The aperture of the larynx which communicates with the pharynx is a large oblique opening, bounded above by the summit of the epiglottis and laterally by the aryteno epiglottidean folds The lower portion is formed by the notch of the arytenoid cartilages Laterally on each side, two eminences are quite prominent in the fresh larynx, an upper pair and a lower pair The lower pair is produced by the carniculæ of the larynx which terminate the summits of the arytenoid cartilages The text-books state that immediately above these there is another pair of cartilages These are the cartilages of Wrisberg The writer has rarely found these cartilages decidedly developed in the white subject Where a prominence exists in the white subject, it is caused by a group of glands Often in these a little cartilage may be found In the negro, the cartilages of Wrisberg are conspicuously developed This point has also been referred to by European writers

The next point refers to the vocal cords, as they are usually designated Between these cords is the fissure of the glottis While physiologically it is correct to speak of the vocal cords, yet anatomically it is not correct to speak of vocal cords These bands are usually spoken of as the inferior thyro arytenoid ligaments There is another ligament extending between the thyroid and cricoid cartilage in front and extending back to the base of the arytenoid cartilages This is the middle crico thyroid ligament, and is connected with the upper border of the vocal membranes This connection is very important If the cricoid cartilage is broken or crushed it must influence the action of the so called vocal cords, for the vocal membranes are connected quite as much at the lower border to the cricoid cartilage as they are at the upper border to the thyroid cartilage

The vocal cords are influenced altogether by the muscles attached to the arytenoid cartilages These are supplied by the inferior laryngeal nerve Another muscle which may influence the movements of the vocal membranes is the crico thyroid This is supplied by a separate nerve, the superior laryngeal Why this muscle should be supplied by a different nerve has not been satisfactorily explained The muscles which operate the arytenoid cartilage are the posterior crico arytenoid, the lateral crico arytenoid and the arytenoid muscle These muscles are sufficient to produce all the movements of the vocal membranes Other muscles, that is to say the aryteno-epiglottidean and the thyro epiglottidean muscles, have been described, but in his experience, the development of these muscles is exceedingly uncertain

Another point is in regard to the connection of the muscles In looking at the origin of muscles we usually consider that they are attached to the surface over which they lie for instance, we look upon the crico thyroid as arising from the posterior lateral surface of the arytenoid cartilage If the muscle is cut across, we find that it arises only at the most remote portion of this surface Between this and its insertion there is a smooth surface

DR J SOLIS COHEN had noticed that the cuneiform cartilages are best developed in those who have the best control over their voices He had regarded them as supports for the ventricular bands The connection of the crico-thyroid membrane with the vocal cords is very interesting There are two supposed paralyses of the larynx which present exactly the same picture One is the paralysis of the thyro-arytenoid muscle, giving the Indian-bow paralysis of the Germans The other is paralysis of the crico-thyroid muscle, giving exactly the same appearance The way to distinguish these paralyses is by placing the finger on the crico thyroid membrane If the membrane vibrates when the patient speaks, the crico thyroid muscle is not paralyzed With reference to the action of the crico-thyroid muscle in phonation, the thyroid cartilage is fixed, and when the attempt to sound high notes is made the cricoid cartilage is drawn up by this muscle The posterior crico thyroid muscle, from its attachment, not only separates the vocal bands, but when they are made tense by other muscles, its action is to increase their tension

DR JOSEPH LEIDY had never been able to see that the crico thyroid muscle was related to the other muscles in the production of sound He was glad to hear the explanation which had been given, which appeared to be a satisfactory one

DR J H MACKENZIE, of Baltimore, exhibited

AN INSTRUMENT FOR FRACTURING THE NASAL SEPTUM,

the chief difference from other instruments of the same class being the great leverage which was obtained

DR CARL SEILER exhibited

AN APPARATUS FOR MAKING SECTIONS OF FROZEN HEADS

Sections made with the machine were exhibited

DR C E SAJOUS, of Philadelphia, presented

A GALVANO CAUTERY HANDLE,

in which the wires were attached in the middle of the instrument, and both the wires and the electrodes were secured without the use of screws The connections within the handle were made of copper and heavier than usual, in order to diminish the resistance

THE PRESIDENT announced the following as the *Nominating Committee* Dr T R French, of Brooklyn, Dr F I Knight, of Boston, and Dr G W Major, of Montreal

AFTERNOON SESSION

DR F H HOOPER, of Boston, read a paper concerning

THE POSITIONS OF PARALYZED VOCAL BANDS

The paper was in part based on experimental work done in the physiological laboratory of the Harvard Medical School, and in part theoretical Specimens and drawings illustrating certain points were shown The reader stated that it was his purpose to inquire into certain influences which might combine to determine the position of paralyzed vocal bands, and to ask whether we are always justified in assuming that a given position of immobile vocal band was indicative of the arrested function of this or that muscle of the intrinsic laryngeal groups The speaker thought that a vocal band might assume different positions in cases of complete paralysis of the recurrent nerve, and he passed in review certain anatomical factors and physical causes which he thought might contribute towards producing the position which might happen to be present when seen reflected in the laryngeal mirror

Dr Hooper concluded by saying that in his judgment the larynx is such a complicated organ anatomically, it is subject to such changes at different stages of life, its shape is so different in different individuals, its nerve supply is so great, the arrangement of its muscles so liable to anomalies, that as surely as one attempts to formulate theories on the positions alone of paralyzed vocal bands—positions which may be controlled by intrinsic muscles of the larynx that are not paralyzed, as well as by those that are—just so surely will one be led unconsciously into erroneous mental inferences

Dr J Solis Cohen read a paper which related the further

HISTORY OF A CASE OF PARALYSIS OF THE POSTERIOR CRICO ARYTENOID MUSCLES,

presented at the first meeting of the Association in 1879, with a report of the autopsy and the exhibition of a specimen

The history of the case was briefly given as follows A man aged 48 years was brought to him with a history that for two years he had suffered from occasional spasm of the larynx so that, on at least two occasions, he had fallen unconscious in the street When a boy he had suppurative inflammation of the left ear, and ever since then the introduction of the finger into the ear would produce spasm of the glottis On examination with a mirror, the doctor found what he then considered to be the picture of paralysis of the left posterior crico arytenoid muscle The examination produced spasm on the other side The patient was directed to carry with him nitrite of amyle to be used when the attacks came on This he did for awhile with good results He subsequently returned with the statement that the day before he had a severe spasm from tickling in the ear While illustrating this he had a violent attack in the office, requiring the use of chloroform to relieve it The next day tracheotomy was performed No other lesion was found at that time The spasms were still produced by irritation of the ear Five or six weeks later, he began to have paralysis of the right vocal band The picture then became extreme, and after this time he never saw the larynx in any other position The man gradually became blind, and developed other symptoms of locomotor ataxia During the four years preceding his death Dr Cohen did not see him, but during this time he continued to wear the tube He was able to speak well without occluding the tube With the condition of conductor paralysis, the doctor thought there was a condition of spasm of the adductors

At the autopsy the left recurrent nerve seemed natural, although it will be remembered that the left cord was the first affected The right recurrent showed a distinct line of demarcation between the healthy and unhealthy fibres Instead of the right muscle being atrophied, it was the left muscle which had undergone wasting

Dr Frank Donaldson, Jr, of Baltimore, read a paper on

THE FUNCTIONS OF THE RECURRENT LARYNGEAL NERVE, FROM AN EXPERIMENTAL STUDY IN THE JOHNS HOPKINS UNIVERSITY

Reference was made to the fact that all the muscles, with the exception of the crico thyroid, are supplied by the recurrent laryngeal nerve The nerve, therefore, contains fibres controlling both phonation and respiration, acting both upon the abductor and upon the adductor muscles He then referred to the experiments performed by Dr Hooper, of Boston, the results of which had been presented at the last meeting of the Association Dr Hooper had found that the constrictors cease to act when consciousness was suspended by the action of ether, and that abduction with dilatation of glottis was obtained by stimulating the recurrent laryngeal nerve when consciousness was suspended. Dr Donaldson's experiments were made to test the correctness of these results In five experiments under states of deep narcosis, slight narcosis and almost complete consciousness, he invariably got adduction of the vocal bands under the application of stimuli with the induction coil at ten In one case in which consciousness had been suspended, under slight stimulation, abduction was produced, while under strong stimulation, adduction was obtained It was then found that abduction was always produced when weak currents were employed, but adduction was obtained when stronger stimuli were used He therefore concluded that the constrictors did not cease to act during profound narcosis or in suspensions of consciousness from any cause, and that abduction is not always obtained when consciousness is suspended It is with weak currents that abduction is produced, but as the stimulation is increased adduction takes place

Dr F I Knight, of Boston, said we must bear in mind that these experiments have been performed upon lower animals, and not upon man, and even if a certain unanimity of opinion is reached, we shall have to adapt these results to the case of man by clinical and pathological observation It does not follow that the same mechanism takes place in the opening and closure of the glottis in man as in the lower animals In regard to the abductor paralysis, he thought the whole question should be decided upon the position of the vocal process without any reference to the cord If the vocal process is found in the median line, it is fair to assume that for some reason the function of the abductor muscle has been abolished A good deal of difficulty has been experienced by observers in determining when the vocal process is in the median line To him the crucial test is by phonation If you get a vertical glottis on phonation, without any movement on suspected cord, you have a sure case

Dr S Solis Cohen, of Philadelphia, said it was important to distinguish between the automatic (respiration), the reflex (cough), and the psychic (phonation) functions of the larynx A well known physiological law is that the resistance which a nerve offers to the transmission of nervous force is inversely as the use made of the muscle which it ennervates No muscle is used more than the abductors of the larynx The resistance of their nerves would *a priori*, then, be supposed to be the least, and Dr Donaldson's experiments show that they respond to a weak stimulus The phonatory muscles are not so frequently used, the resistance of their nerves, though low, is higher than that of the respiratory fibres The respiratory impulses traverse the nerve continuously, and additional stimulation, whether reflex (irritation of the superior laryngeal), producing cough, or psychic, for purposes of phonation, produces adduction of the vocal bands There is a local centre in the medulla, the vago accessorius, nucleus for all the laryngeal muscles Moderate stimulus from the respiratory centres opens the glottis for respiration, increased stimulus opens it farther, a greater increase, say by reflex irritation, closes it for cough An impulse from the cerebral cortex, the centre of voluntary motion, closes it for speech

(*To be concluded*)

OBSTETRICAL SOCIETY OF PHILADELPHIA

Special Meeting, April 15, 1886

The President, B F Baer, M D, in the Chair

W H H Githens, Secretary

(*Continued from page 642*)

Dr H A Kelly exhibited the

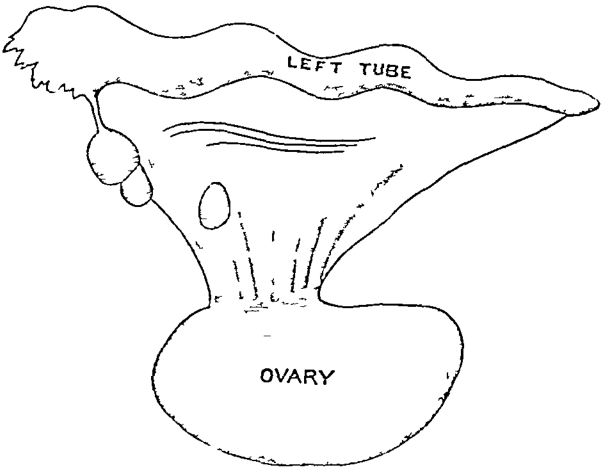
OVARIES AND TUBES FROM A CASE OF CHRONIC OVARITIS, SALPINGITIS AND PELVIC PERITONITIS

Also, the right ovary and tube from a case of

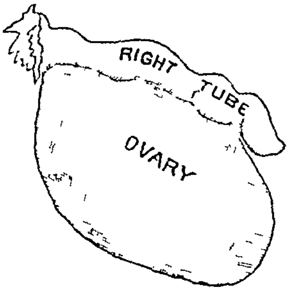
CELLULITIC CONTRACTION OF RIGHT BROAD LIGAMENT WITH DISAPPEARANCE OF THE MESO SALPINX AND COHERENCE OF OVARY AND TUBE

of which the following is the history H P, married, age 32, four-parous, has always been irregular in her menstrual function, the flow generally appearing from ten days to two weeks later than expected, and being scant Her last confinement was eleven months ago Labor was slow, but no instruments were used The child died in two months Ten days after delivery she had an attack of "typhoid fever," (*sic*) and since then she has never been well During the fever, which lasted many weeks, she had constant severe pain in the right ovarian region, and had repeated chills and flushes of heat She has at present severe pain in the right ovarian region, and constant headache, is unable to work or exert herself in any way She has not now menstruated for two months, although regular before She has a leucorrhœa, which is intermittent in character Bimanual examination reveals an enlargement on the right side extending from the middle of the hypogastrium two and a half inches to the right, downwards to the pubis and upwards almost half way to the umbilicus It is most prominent above, very tender and semi-fluctuant, every movement of the mass carries the cervix with it The cervix points to the left and the right fornix is very shallow The mass has no firm attachment to the pelvis but is easily movable It seems to spring from the right cornu-uteri February Pain and sensitiveness great The right fornix obliterated and the uterus drawn bodily to the right side by a shrinkage in the mass There is a mass which is as hard as a bone on the left side, like a finger, high up behind the vagina, pointing down in its axis March After faithful and prolonged treatment consisting for the most part of rest with counter-irritation in the vagina and on the abdomen, and hot douche and glycerine plug, I made an explorating incision, at my private hospital, on March 27, in the presence of Drs R P Harris, Chas Herman Thomas, P G Clark, Marie B Werner, Boyle of Kansas, Bull of Missouri, Baldy and I W Mecaskey to whose courtesy I was indebted for the case, and assisted by Dr Jas Hoffman The right cornu uteri was found elevated and matted with a mass of mesentery in which it was completely encapsulated This was slowly detached layer by layer, and the vermiform appendix separated for an extent of two inches The tip of the appendix gave rise to troublesome bleeding finally checked by the cautery An enlarged ovary with a withered tube intimately adherent to its periphery was then raised with great difficulty, a black walled cyst, about one and a half centimetres in diameter, burst and a quantity of grumous matter escaped into the peritoneum The ovary and tube were removed with great difficulty and a part of the hilum was left in the grasp of the ligature This was carefully burned

The illustration gives a correct indication of the structural changes in the right ovary, tube and ligament The left ovary and tube, which were free and sound, I also removed as I was anxious to stop all determination of blood to the uterus The figure shows well the contrast between the two The operation was protracted, lasting one and three quarter



hours The patient died on the seventh day of one of those remarkable insidious attacks of peritonitis She appeared to be doing well until the seventh day, when I found her with a wild frightened look and a pulse of 200 She had no pain at all I broke up the adhesions in the lower part of the wound, which looked well, but I could not reach anything within the wound, and she died within two hours Dr R P Harris was present at the autopsy a few hours later The recti had a deep red unhealthy appearance, and a few spots of pus lay in the floor of the wound, opened down to the peritoneum The peritoneum was firmly glued together and my effort in the morning had not penetrated it, for as soon as the adhesions loosened a large quantity, at least a pint, of brown pus rushed out, and I found the whole posterior part of the pelvis shut off from the general peritoneum by firm agglutination of the viscera above and full of the same material My chief anxiety was to find the vermiform appendix and see if I could blame it for any share in the result It was found with difficulty and was covered with a thick finger of lymph The sepsis came from the matter which escaped from the ovary I say this for I have never yet seen sepsis in any clean case Then in looking back for unnoticed symptoms for future guidance in such cases, several points deserved closer attention than they received *First* She complained more than usual of pain in the first three days *Second* The pulse remained about 112 instead of dropping below 100, as usual *Third* She wandered a little occasionally, insisting once that she saw a man in the room She was more nervous about herself than any of my other cases had ever been, often insisting on sending for me in the night These signs, taken together, are certainly significant in the absence of pulse and temperature indications



Dr R P Harris saw both the patients from whom these specimens were removed The ovary in the latter case presented a very peculiar appearance, it was cartilagenous, with small cysts The material escaping from these cysts caused septic peritonitis The first patient was wonderfully changed by the operation She was free from pain for the first time in twenty years, and could scarcely be kept quiet, so great was her joy at her release

Dr Howard A Kelly reported a

UNIQUE CASE OF EXTRA-UTERINE PREGNANCY, COMPLETE REMOVAL OF THE SAC AND CONTENTS

Mrs J B, 22 years of age, married three years, of medium size, well built, but rather pale and worn looking, has been twice pregnant, the first being a premature still-birth, the second a cross-birth, necessitating turning by the feet Since the last pregnancy she menstruated seven times In July she menstruated the last time for four months, when a flow came on (in November), at which time she passed a piece of flesh called by a doctor a "false conception" Previously to this she had noticed a swelling in the right ovarian region which gave her some pain This pain was constant until the flow came on, when it was relieved In December, three weeks after this flow, she thought she felt life and believed she was pregnant She then had colastrum and a dull pain in the breast, and the nipples were coated with a waxy secretion Examination A tense, smooth, elongate, ovoid sac lay in front of the uterus (which reclined in the hollow of the sacrum), and rising out of the pelvis pointing over the pubis, reached half way up to the umbilicus as she reclined on her back The tumor was very tender on pressure and presented a remarkable smoothness and uniformity of its surface It had a tense fluctuant feeling, and was distinctly movable as distinct from but closely connected with the right side of the uterus She menstruated regularly in January, February and March, the flow being lighter in color and much more profuse, lasting two or three days longer than her normal menstruation On March 13 she was menstruating freely, and the notes state "the uterus lies, small in size, in the sacral hollow, and in raising the finger from the cervix to the anterior vaginal wall, an elongate, ovoid, tense cyst is felt on the right side, it is about 3½ inches long by 2½ wide The cyst lies in the plane of the superior strait The anterior extremity of the ovoid lies at the pubis, and its posterior, attached extremity at the right *cornu uteri* A well defined sulcus exists between the tumor and uterus, and the two are connected by a short but distinct pedicle The tumor is very smooth, and of a remarkable rubber ball elasticity It is movable over an excensus of one or two inches, but too tender to manipulate further" These notes were made a week before the operation, which was upon March 20 I then wrote to Dr R P Harris that I expected to operate upon an extra uterine cyst, and upon March 20, assisted by Dr Joseph Hoffman, and in the presence of Drs R P Harris, Chas H Thomas, Marie Werner, Wm Stuart, Baldy, Chas M Wilson, James Gibbs, R Keely, Paris G Clark, McConnell, and others, the sac and its contents were removed The belly walls were fat The incision was about three and a half inches in length, through the linea alba, beginning about one inch above the pubis The sac wobbled about so in the pelvis that it was hard to bring its globular form up under the line of incision It felt at first like an enlarged uterus, but the uterus lay retroposed, anteflexed, reclining in the sacral hollow The tumor was raised and brought out of the pelvis by passing two fingers in front of and under it, hooking it up and revolving it on the axis of its attachment at the broad ligament, it was then delivered at the linear incision by pressing the walls outward and towards the patient's back until it slipped out, it was then transfixed below its base and tied, and with the ovary and whole of the right fallopian tube, was removed intact The cyst was reddish blue in color, and developed in the free margin of the right fallopian tube, its longest diameter crossing the axis of the tube at right angles Pure water was used for the sponges, and the instruments were kept in a dry pan No antiseptic of any sort was employed Everything was thoroughly clean and prepared beforehand, and no antiseptic was needed The whole operation from beginning to complete closure lasted forty minutes Silkworm gut sutures, about four to the inch, were used to close the wound, and with a little iodoform powder and dry absorbent cotton the dressing was complete The sac was about three inches long by two and a half wide, smooth and slightly rugous in its long diameter Dr Charles Hermon Thomas incised it at its free extremity, cutting through the placenta into the amniotic sac, which did not contain a drop of fluid The hands and then the head of the brownish, exsanguine fœtus protruded, its cranial bones well developed There was not the slightest fetidity The whole fœtus was well formed and perfectly preserved It was a male, measuring 5¾ inches in length, the cord was five inches long, twisted from left to right The recovery was as rapid and perfect as after any simple abdominal operation An objection which naturally presents itself, and one which has been urged, is this Here was an extra-uterine cyst containing a mummifying fœtus in just the condition we try to obtain by faradic fœticide Why interfere with it at all? My reasons were several First, my patient was constantly suffering from a painful tumor Second, she had deteriorated greatly in health, and in place of her usual fresh and rosy complexion, was looking sallow and wan, and was very despondent Third, the facility of the operation was manifest, and my bimanual examination revealed all the peculiarities of the case before making the section Fourth, the very real danger of peritonitis and the possibility of the later discharge of the fœtal parts by protracted suppuration And further, I was acting in accordance with the practice of such eminent authorities as Lawson Tait and Olshausen, who counsel early interference in all pelvic tumors where the probabilities of success are good It must be remembered in any critique of the case, that it presents features utterly unlike any other abdominal pregnancy ever recorded as operated upon Dr Harris's remarks will show that the crisis is not always passed when the fœtus is killed by electricity

Dr R P Harris said the case reported by Dr Kelly had as clear a history of extra-uterine pregnancy as we ever find in the *very early period* of ectopic gestation, *when*, it cannot be claimed, that a positive diagnosis can be made We can, however, very closely approximate it, as was done prior to this operation The woman had been twice normally pregnant, she ceased to menstruate on July 16, 1885, and there was no recurrence until November 17, a period of four months She considered herself pregnant, and as the menstrual flow of November lasted a week, was excessive, and she passed, as she termed it, "two pieces of flesh," she thought she had aborted Having seen her in the operation, and upon several occasions since, I learned from her that her menstrual periods usually lasted about three or three and a half days, but had increased to a week or thereabouts, after the return in November

The development of the breasts, the presence of astrum in them, the discharge of the decidua, the detection of the spherical tumor connected to the right *cornu uteri*, the decrease of this in size after the decidual expulsion, and the prolongation of the menstrual periods, all pointed to the existence of a right fallopian pregnancy and a dead fœtus When the tumor was brought into view in the operation, it was seen to be of a reddish blue color, which is common to fœtal cysts, and about three inches in diameter When opened after removal, the placenta was found at the top, and the cyst empty of amniotic fluid, which had been removed by absorption The fœtus was a male, 5¾ inches in length, and to judge by its size, degree of cranial ossification, and mark of sex, it must have died near the end of the fourth month Such a fœtus, at the time of its death, must have occupied a cyst as large as a cocoanut The loss of fluid in the cyst made it sufficiently flaccid to admit of its being drawn upon so as to form a pedicle for transfixion and ligation Fortunately for the woman, the cyst retained its integrity, the fœtus perished, and there was no peritonitis to produce adhesions, the operation was therefore as simple as an easy ovariotomy, and no more dangerous

There can be no question in my mind that under all the peculiar circumstances of this case it was proper to remove the fœtal cyst for the purposes of relieving the pain felt in it, and of checking the menstrual loss The question might be asked, Why operate in such a case more than in one where fœtal death has been produced by the farradic current? I answer, that under the same peculiar sufferings and advantages the exsection might be called for The after history of the cases of faradic fœticide has yet to be written Thus far, there has been no death, immediate or remote, but there have been attacks of peritonitis, and there may be other troubles from the dead fœtus after a long period Very little has been recorded of the ill effects produced by ectopic fœtuses, which have died in the second, third and fourth months of tubal or abdominal gestation We know that a fœtus of the fourth month has been passed whole from the rectum, and that one still smaller has been vomited, but death has rarely taken place within an unruptured cyst, in the second, third or fourth months, and we therefore do not know by the past what may be likely to happen in some of the cases subjected to faradization Thus far the method has much to recommend it, by its safety of application, and by the present health of its subjects Fœtal death being followed by absorption of the amniotic fluid, there is no longer any danger of the cyst rupturing from tension, and the woman's life is saved

The first to destroy a fœtus by electro magnetism in the United States, was our fellow member, Dr Joshua G Allen, who has now operated three times with success, and all of the women are still living Case 1, 1869, and Case 2, 1870, were illegitimately impregnated, and both have since married Case 1 has remained childless, she continued well for two or three years, and then went to the Jefferson College Hospital, where she was supposed to have rheumatism, but as the pain was in the lower part of the abdomen on the side corresponding with the seat of the fœtal cyst, Dr Allen attributes the attack of pain to the presence of the foreign body, the age of the fœtus was computed at three months In Case 2 the age was believed to be eight weeks, and the woman did well for a year or two, when she had an attack of peritonitis lasting about three weeks She subsequently married, bore a female child, now ten or eleven years old, had a second attack of peritonitis about a year later, and four or five years later, a third Although severe, Dr Allen did not regard the attack as dangerous to life

Dr J C Reeve's patient has had a probation of six years, and has had no after trouble to note

Dr C L Billington writes me that his patient has improved in health, and that although the fœtus was computed to have a three months' growth, "there was no tumor perceptible five or six months afterwards"

Dr Lusk's second operation was followed by a peritonitis which confined the patient to bed for two months She is now near her maturity of pregnancy and has had no trouble during gestation from the presence of the tubal sac

Dr Bache McE Emmet's case never showed the the slightest effect from the presence of the ectopic fœtus up to the last report, about a year ago

Dr Garrigues examined his patient two years after the operation, which was performed upon a fœtus of "barely two months," and "the tumor to the right of the uterus had entirely disappeared" She had no longer any orgasm in sexual intercourse

Dr P F Mundé reports that at the end of two years his patient remains perfectly well

In her menstruation, which was in progress when I last saw the patient of Dr Kelly, the loss was restored to its normal moderation, and she was free from pain

Dr **Baer** spoke of a case of extra uterine fœtation which had gone to full term, and in which laparotomy was performed thirteen months after the death of the fœtus The mother had shown great loss of vitality, and the tumor felt loose in the abdominal cavity and promised to be easy of removal, but when the abdomen was opened, adhesions were found so numerous and strong that removal would not be safe The opening in the sac was stitched to the abdominal wound The temperature did not rise and there was full recovery This was an instance of tubal pregnancy carried to full term

Dr **Parish** said we would find, in the large majority of these cases, that at an early period adhesions would be slight and removal easy Operation after rupture of the cyst is not complicated by adhesions except those formed by the placenta, which are so vascular as to defy separation, and constitute the great danger Prior to the fourth month before such adhesions are formed, it is safe and easy to operate It is a favorable time to operate after the death of the fœtus, because the maternal tissues lose the extreme vulnerability that exists during the life of the child

Dr **Longaker** had been surprised at the absence of peritonitis after so much pain and tenderness

Dr **Kelly** remarked that the pain had always been non febrile, there had been no elevation of the temperature or pulse

There had, in this case, been no sense of contraction in handling the tumor, as had been noticed in hydro-salpinx

L Tait had heard the uterine souffle in one case at his first examination, but could not find it again Dr Kelly has a case of extra uterine fœtation on hand now, and is waiting for the death of the fœtus, when he will operate Ohlshausen has formulated the rule that "any abdominal tumor as large as the fist should be removed"

FOREIGN CORRESPONDENCE

LETTER FROM LONDON

(FROM OUR OWN CORRESPONDENT)

Royal College of Surgeons of Dublin, Honors to Pasteur, Huxley, Paget, Lister, Wells and Marshall—Vivisection Experiments in 1885—King Theebaw's Hairy Family—Anthropological Society of Bombay—Bulbar Paralysis

The Lord Lieutenant and Lady Aberdeen, together with the Prince and Princess Edward of Saxe Weimar, were present on the afternoon of April 28, at some interesting ceremonies in the Royal College of Surgeons, Dublin First, Honorary Fellowships of the College were conferred on MM Pasteur and Huxley, Sir James Paget, Sir Joseph Lister, Sir T Spencer Wells, and Mr John Marshall From various causes Sir James Paget was the only one of the recipients who was able to be personally present Next was unveiled a statue erected to the memory of William Dease, one of the founders of the College and its first President He died in 1798 This statue which is erected in the entrance hall, is the gift of his grandson, Mr O'Reilly Dease, who has also presented the Butcher Museum for the accommodation of surgical casts This Museum was formally opened The honors of the reception was performed by Sir Chas A Cameron the President, and Mr William Stokes, the Vice President, the former of whom made an interesting speech eulogising William Dease and Sir James Paget

The report from inspectors on experiments performed on living animals during 1885 has just been published The total number of experiments performed during the year was about 800 Of these 210 were done under the restrictions of the license alone, and eighty two lecture demonstrations under similar restrictions As regards the amount of pain involved in these experiments, in all of them, except those performed under special certificates, the animals are rendered insensible during the whole of the experiment, and are not allowed to recover consciousness With respect to the experiments under special certificates, which dispense either partially or entirely with the use of anæsthetics, no less than 328 consisted, so far as any operative proceeding was concerned, in simple inoculation or hypodermic injection, either with some morbific virus or for the purpose of therapeutic inquiry, and in which the administration of an anæsthetic to which all animals have a great repugnance, would only entail needless annoyance and distress. In this class of experiments, when the inoculation took effect at all, any appreciable suffering could be likely to ensue only in those cases in which some morbid affection was induced as in ordinary vaccination. It is impossible to give any precise estimate either of the number of cases thus affected, or still less to appreciate the trifling and brief distress rather than actual pain that would be caused. Considered in this way from the returns that have been received from the various operators, and from other considerations drawn from their reports, it appears that the number of animals that suffered any appreciable pain might be estimated at thirty-five or forty and these for the most part frogs. Although the number of experiments in 1885 was nearly double those performed in 1884 the increased number consisted of experiments not, or scarcely involving any appreciable increase of suffering of the animals employed.

Ex-King Theebaw's famous hairy family, which he long kept jealously at Mandalay, are coming to Europe for exhibition. The family have been renowned in Burmese history for many years, and the present members, a mother and son, form the fourth generation known. The mother is 63, quite blind, and usually sits motionless on a platform, occasionally fanning herself and speaking in a low, sweet voice. She was seen and described by Colonel Yule when on a mission to the court of Ava in 1855. Save her hands and feet, she is covered with long soft hair, like her son, who is covered even to the drums of his ears, the hair in some places being five inches long. The man is of medium height, with pale brown skin, and is fairly friendly, having been partly educated and married to a maid of honor. Neither he nor his mother have either canine teeth or grinders.

An Anthropological Society has been founded in Bombay in order to gather and classify information respecting the native races of India. The scheme is eagerly taken up and a large number of members have already joined, under the presidency of Mr. Tyrell Leith. As a native member points out, the Bombay Presidency affords excellent ground for commencing such work considering the mass of aboriginal tribes in the hills and jungles, descendants of the non-Aryans driven out by the Aryan invasion. They are generally known as the "black races," and preserve native traditions fully 3,000 years old.

An interesting case of bulbar paralysis has recently been under the care of Dr. Broadbent, and was mentioned by him at the last meeting of the Harveian Society. The case occurred in a man aged 35, who was admitted as an in-patient into St. Mary's Hospital on January 29, 1886. While a soldier serving in India he had suffered from ague, syphilis, sunstroke, dysentery, etc. The first thing he noticed was that about a year before admission he began to lose his voice, and the food collecting in the sides of his mouth, gave him difficulty in swallowing it, necessitating manipulation with the fingers, the saliva dribbling away. These conditions, along with a gradually increasing muscular weakness, had continued, with now and then a slight remission, until admission, when he was unable to speak except in a whisper, every syllable necessitating a long forcible expiration. The tongue was small and shrunken, could not be properly protruded, but could be moved from side to side. There was impaired movement of all the facial muscles of expression, traces of the reaction of degeneration, general muscular wasting, increased superficial reflexes and good sensation. There had been a general improvement since admission in all these symptoms, the chief trouble arising from the profuse amount of saliva with which the pharynx and larynx were frequently blocked. The condition of the patient at the meeting included all the foregoing symptoms, with the addition of pain in the left side of the face and head, with occasional nausea. The ophthalmoscope showed pallor of the centre of the discs and very small vessels, vision was consequently impaired. The pupils were somewhat contracted, but retracted to light and accommodation. Hearing was also impaired. The heart's action was weak, but regular, respiration was chiefly abdominal. The man walked with a stiff but steady gait, had great difficulty in going up stairs or in rising from his seat, owing to weakness of the extensor muscles of the thigh, which, in common with most of his extensor muscles, were wasted, exhibiting to a slight extent the reaction of degeneration. The superficial reflexes were exaggerated, and there was ankle and thigh clonus in the left leg. Sensation was complete. Treatment had consisted of rest in bed, with 30 grains of iodide of potassium daily.

BOOK REVIEWS.

A SYSTEM OF OBSTETRIC MEDICINE AND SURGERY, Theoretical and Clinical. For the Student and Practitioner. By ROBERT BARNES, M.D., Obstetric Physician to St. George's Hospital, Consulting Physician to the Chelsea Hospital for Women, etc., and FANCOURT BARNES, M.D., Physician to the Royal Maternity Charity and to the British Lying-in Hospital, Assistant Obstetric Physician to the Great Northern Hospital, Physician to the Chelsea Hospital for Women. 8vo., pp. 884. Philadelphia: Lea Brothers & Co. Chicago: Jansen, McClurg & Co. 1885.

In the preface to this work the statement is made that "the history of gestation, of puerpery, of the mechanism of labor and of hæmorrhage, is contributed by Robert Barnes, while much of that which relates to the prophylaxis of puerperal diseases, and the description of operations, is contributed by Fancourt Barnes. Still the production is essentially a joint production." That part of the book which treats of embryology is contributed by Prof. Milnes Marshall. The authors justify their action in calling upon Prof Marshall by saying that "no man can hope to master the facts and science of embryology unless he can spend several hours daily in the physiological laboratory "

The authors claim that the immediate purpose of the work is to furnish a handbook of obstetric medicine and surgery for the use of the student and practitioner, and they have succeeded well in their purpose It is not an exaggeration to say of the book that it is the best treatise in the English language on obstetrics yet published, and this will not be a surprise to those who have been familiar with the work of the elder Barnes

The limits of this review make it impossible to analyze in detail even the chapters of the work, and hence mere mention of one or two special subjects must suffice Unfavorable criticism may seem presumptuous, but the authors have hardly given as much attention to the application of Braxton Hicks's method of bimanual version in *placenta prævia*, as the matter deserves, especially in view of the very favorable results which have recently followed that practice in Germany (For particulars see *American Journal of Obstetrics* for December, 1884—a report by Dr Richard Lomer, assistant at Schroder's clinic in Berlin)

In relegating the so called and formerly disputed "*milk fever* " to the past the book simply adds the weight of its authority to the best teaching of the time The classification of puerperal fever may meet with some opposition, but is clearly and sensibly put, and will probably meet more approbation than opposition

What the author says in regard to the significance of kyesteine in the urine (p 175) is an amusing illustration of the strength of a prejudiced opinion After stating that Parkes, Kane and Braxton Hicks have carefully investigated the subject and have decided that kyesteine has been found in the urine of virgins, and appearances very similar to it in that of men, Barnes remarks "We may in conclusion state that, assenting to the propositions of these authorities, we have seen several instances in which a confident diagnosis of pregnancy expressed on the evidence of this appearance proved to be correct "

Perhaps the only serious fault of the book is the lack of fulness and completeness in the index So good a book deserves a better index than this one has In conclusion it is not an exaggeration to say that every practitioner who desires to have the best obstetrical opinions of the time in a readily accessible and condensed form, ought to own a copy of the book

A TREATISE ON NERVOUS DISEASES, THEIR SYMPTOMS AND TREATMENT A Text Book for Students and Practitioners By SAMUEL G WEBBER, M D Clinical Instructor in Nervous Diseases, Harvard Medical School, member of the American Neurological Association, etc , etc 8vo pp ix—415 With Illustrations New York D Appleton & Co 1885 Chicago Jansen, McClurg & Co

The author disarms hostile criticism by the statement in his preface that the book is not written for specialists The general introductory chapter on methods of examination in nervous diseases, together with a consideration of certain general conditions common to many forms of nervous lesion is well written The general classification made by the author is 1 Diseases of the Brain, 2 Diseases of the Spinal Cord, 3 Diseases of the Peripheral and Sympathetic Nerves, Unclassified

The anatomy of the brain is illustrated by fifteen figures taken from Ecker, Wernicke, Erb and Ferrier, some of the drawings being modified in reproduction The arrangements of the relation of the text to the drawings is unfortunately such that the combined impression obtained from them is much less clear than it both ought and might be The anatomy of the cord is illustrated by Hammond's colored plate, modified from Flechsig, and leaves nothing to be desired The arrangement of colors is such that the relations of the direct and crossed pyramidal tracts may be seen at a glance, and the text is clear and direct

Among the "unclassified" diseases the author has given a satisfactory account of the comparatively rare and interesting disease *tetany*

The general arrangement of the book is excellent, but the clinical pictures of the various diseases are not so closely cut and systematic as it seems might be easily possible

A list of the authors consulted, together with the titles of the articles by each, is given at the head of each chapter

In his discussions of treatment, the author shows that he is not a friend of nihilism in therapeutics, and also that he is familiar with the subject of which he writes

For the purpose designed, for students and practitioners, the book is a valuable addition to the literature of the subject, and will prove a reliable clinical guide in the hands of any one who reads it carefully

RESEARCHES INTO THE ETIOLOGY OF DENGUE[1]

BY J W McLAUGHLIN, M D,

OF AUSTIN, TEXAS

The epidemic of dengue which prevailed throughout the State of Texas during the fall of 1885, was unusual in many respects, for example

1st In its universality
2d In the violence of its symptoms
3d In its manifest contagiousness
4th In the protracted convalescence of its subjects
5th Its hæmorrhagic tendency
6th In its numerous sequelæ

From Galveston, located in the South eastern portion of the State, it spread, in the course of a few months, to its Northern border During this time almost every city, and many of the country districts within these limits, fell under the epidemic influence of this disease In the city of Austin about 16,000 cases of dengue occurred during this time, out of a population of 22,000 inhabitants I am informed that other cities and sections suffered as severely, *i e*, had as many cases in proportion to the population as did Austin

Many cases where direct contagion was the cause of this disease came under the observation of the writer He has no doubt that by this means it was carried and spread from one neighborhood to another, and from the city to the country by infected individuals The violent type of the disease, the protracted convalescence of its victims, and its sequelæ, were unusually prominent in this epidemic The *first*, by the suddenness of its invasion, often with an initial chill, its pyrexia, its excruciating pains, nausea, and the constancy of its exanthemata The *second*, by the mental and physical prostration which follows its defervescence, this often continues for weeks or months, with anorexia and indisposition to perform any kind of labor

The sequelæ most frequently observed were dysentery, entero-colitis, nephritis, bronchial and gastric catarrh, abscess, glandular enlargements and eruptions of the skin It would seem from the peculiar clinical history of dengue, especially its contagiousness and its epidemic character, that it is a specific disease, that micro organisms are the source of its infection, and these micro organisms find in the blood a suitable environment for their growth and multiplication

To determine the correctness of this theory, and if possible to obtain information with reference to the etiology and pathology of this malady, which is the scourge of our southern country, and especially as medical literature is absolutely silent upon these matters, the following experiments were conducted, with hopes that they would lead to a more rational therapy, or perhaps indicate some method of protecting individuals against dengue by means of inoculating them with the attenuated virus I found, however, that I had neither the time nor means of carrying out the necessary investigations to determine the practicability of this hope, or of accomplishing these latter anticipations A physician engaged in active practice has but little time, whatever his inclination may be, to indulge in experimental work The demands of his patients and his creditors too frequently prevent his giving that time to original work or pure scientific labors which the interests of his profession demand

During the six months occupied in making these investigations, one-half, and frequently two thirds, of nights succeeding days of toil, were utilized in these labors, they possessed my interest, I managed to give them much of my time The work actually performed during this time is embraced in the following statements

1st Blood, which was obtained from living subjects during the various stages of dengue, was microscopically examined, (a), directly, that is, without the addition of any chemical reagents, (b), after it had been subjected to the action of certain chemical reagents, viz glacial acetic acid, with and without dilution, caustic potash in solution, both weak and strong, chloroform, and ether

2d This blood was carefully dried upon sterilized cover glasses by passing these through the flame of a spirit lamp, and then subjected to the action of various staining reagents

3d Dengue blood obtained from living subjects was introduced, upon the point of a platinum wire, into test-tubes containing sterilized culture jelly prepared for this purpose

These tubes were closed with plugs of sterilized cotton, then placed in an incubator, where the temperature was kept at 100° F for the growth of such organisms as were contained in the blood

4th Blood was drawn directly from the veins of a living subject into a series of sterilized glass bulbs, which were united by a capillary tube. This was performed in such a manner that it seems impossible for germs from the air, or by other accidental means, to have gained an entrance into these bulbs. These were also kept in the incubator, at a temperature of 100° F.

---

[1] Read in the Section on Practical Medicine at the Thirty Seventh Annual Meeting of the American Medical Association, St Louis May 1886

5th. The matters vomited and urine passed by dengue subjects were subjected to microscopic examinations.

It is the purpose of this paper to record the methods adopted in making these examinations, and the results obtained from them. Before entering into the technique of these methods, which are necessarily tiresome, I think it better to submit the following outline of the results obtained. In the blood examined directly, or after its treatment with the chemical reagents already referred to, stained or unstained, I invariably found, often in great numbers, in the cell elements as well as in the plasma, micrococci about $\frac{1}{20}$ to $\frac{1}{30}$ the diameter of the red cells, spherical in shape, and red or purplish in color; when these were seen in great numbers one layer superimposed upon another; frequently seen in the cultures, they appeared of a black or brownish color, but when seen singly or in thin layers in the blood or in the cultures, the red color is always distinct and characteristic.

During the development of this organism, at some period in its life history, from causes which I do not understand, it becomes surrounded by a gelatinous envelope; this I have frequently observed in the blood and in the cultures alike. I always succeeded in growing in the culture tubes, upon the surface of the jelly, micrococci, and no other form of bacteria, which in color, size and behavior, are identical with those seen in the dengue blood. The blood contained in the series of glass bulbs was examined, some after the lapse of six weeks, others at three months. In both instances I found that the blood contained a pure culture of micrococci which, in all respects, were the same as those which I had previously seen in fresh blood, and grown upon culture jelly, in culture tubes; these were apparently composed of micro organisms held together by their gelatinous envelope, or capsules; at the end of the casts, where the micrococci were less firmly attached, or cemented together, their shape, size and color were found to correspond with those seen in the blood, or grown in the culture-tubes, or bulbs.

The microscopic examination of the blood for micro-organisms is attended with many difficulties. The first care is to obtain blood for examination that is not contaminated with bacteria from the air, or from other outside sources. In all examinations of the blood, or other portions of the body, for micro-organisms, every precaution against its accidental contamination, or the introduction of germs from outside sources, should be taken; without such precautions all investigations of this sort would be worthless and delusive.

When it is remembered that air and water contain large quantities of micro-organisms, that these adhere to the glass apparatus, metal instruments, fingers, and clothing of the operator, and that bacteria will quickly form in distilled water, and in staining fluids required in such examinations, the necessity of thoroughly washing and then sterilizing by heat and by chemicals, when this is practicable, all articles used, and by boiling and filtration, or other efficient means, becomes at once apparent.

The methods which I adopted to secure cleanliness and sterilization of all glass apparatus, instruments, and other agents used in these experiments, may not have been absolutely perfect in every instance. I made them as nearly so as the means at my command would allow. I am constrained to believe, from the uniformity of the results obtained, notwithstanding some minor defects in the detail of my technical methods, that, in the main, these were sufficiently exact to exclude serious errors.

The second difficulty which confronts him who examines blood for schizomycetes, is to dry the blood on the cover-glass without overheating, and thus disintegrating it.

The third difficulty is, to not mistake for micro-organisms certain elements and granules found in normal and pathological blood. These mistakes have occurred frequently, and wrecked many a beautiful hypothesis. That the reader may know and appreciate the difficulties to which I refer, I quote from the recent work of Dr. F. Huppe.[1] "The examination of blood for bacteria offers very great difficulty, because in the normal blood within the vessels, and in the normal disintegration of the healthy blood, granular elements are present, or are formed, which under certain pathological conditions, in anæmic state and in fever, are increased in number, and can be easily mistaken for micrococci.

"They have already been often confounded with micrococci, and are almost daily mistaken for them, *e. g.*, the renowned syphilitic corpuscle, and the so-called organisms of the venom of serpents. Here belongs also much of what has been spoken of as the development of bacteria from nitrogen molecules, from microzymen, or from the anamorphosis of protoplasm. An exact study of these granules of the blood is, on this account, an indispensable desideratum in bacteria investigation.

"These granular forms further constituent parts of the cellular elements of the blood, and on this account again are of interest in ætiology, because there are parasites which are similar to the amœboid cells, *e. g.*, those monads found by Lewis in the blood of rats, by Koch in the blood of marmots. The elements of the blood, which directly or through their granules may be confounded with micro organisms (with the exception of the red blood corpuscles), and the products of their disintegration), are divided according to Ehrlich into

"1st. Lymphoid elementis, (a), small lymph cells, (b), large lymph cells.

"2d. Myeloid cells (eosinophile).

"3d. Undetermined spleen and [or] marrow. (a), large mononuclear cells, (b), transitional forms, (c), polynuclear.

"The small lymphoid elements are somewhat smaller than the red blood corpuscles, possess a very large nucleus, so that there is very little or no protoplasm to be seen

---

[1] 'Methods of Bacteriological Investigation' by Dr. Ferdinand Hüppe. D. Appleton & Co., New York. 1886.

"The large lymph elements are a further development of the first, and are only to be differentiated from them in this, that they possess, around the large nuclei, a distinct border of protoplasm

"The myeloid elements are large round cells, with large oblong nuclei

"The mononuclear cells are about three times the size of the red blood corpuscles, possess round or oval nuclei of large size, and a considerable mass of protoplasm The mononuclear transitional forms are to be differentiated from these cells only in this, that the nuclei are no longer round or oval, but have become indented

"The polynuclear elements are somewhat smaller, but still are always larger than the red blood corpuscles, and their nuclei show, as a further differentiation, a polynuclear form, these are the true white blood corpuscles

"The granular elements, or granules, which are present in the cells, and which become free in the destruction of the same, are divided with respect to their reaction to aniline dyes

"The *α* or eosinophile granule is coarsely spherical, strongly refracting, and can be stained in all the acid aniline dies It is present in the myeloid elements, seldom in the normal blood, and its number is greatly increased in leucæmic processes

"The *β*, or amphophile, is formed especially in the marrow, very often in the leucocytes in the blood of rabbits and guinea pigs, and can be stained by acid and basic aniline dyes

"The *γ*, or basophile plasma cell granule, can be stained, like the bacteria, by the basic aniline dyes These granules are coarse, slightly refracting, almost completely wanting in normal human blood, increased in leucæmic processes, and are present normally in the blood of the lower animals, especially the white rat

"The *δ*, or basophile granule, is fine, and can be stained in basic aniline dyes, and forms a constituent part of the large mononuclear elements

"The *ε*, or neutrophile granule, is very fine, and fills the polynuclear elements of the human blood quite thickly, is present sparsely in the transitional forms, and very seldom in the mononuclear elements It can be stained by the neutral dyes Without recourse to staining, these granules, as a whole, and also the products of the disintegration of the red blood corpuscles, may be confounded with micrococci

"By systematic staining with aniline dyes the *α*, *β* and *ε* granules can be excluded An error is then possible only with the *γ* and *δ* granules, because these are stained in the basic aniline dyes, the same as the bacteria. These last, on account of their fine grain, can, with comparative ease, be differentiated from micrococci, and have not, as yet, been confounded with them

"The plasma cell granules on account of their medium size, come so near to the known forms of cocci that not only the individual free granules in the blood have been considered as cocci, but even the so called plasma cells in the tissues have been described as colonies of cocci They can, on purely morphological grounds, be differentiated from them in this way, viz That they do not all have the symmetrical appearance of the cocci, but present the greatest differences in the size of the granules

"If it be desired to examine the blood for bacteria, a small drop is rapidly spread out in a thin layer, dried, fixed, and then passed three times through the flame, and then stained in the ordinary manner In such preparations the bacteria are sufficiently stained, but not the granules"

Prolonged heating of cover glass preparations, or sections containing these granules, is necessary to their successful staining The method of doing this, which is recommended, is to subject the specimens, in a drying oven, to a temperature of 240° F for an hour, they are then prepared for the staining process, and may be stained with their respective dyes, acid, basic or neutral, in the manner described

As micrococci and other forms of schizomycetes do not require this prolonged heating in order to their successful staining with the aniline dyes, renders this difference in the behavior of the protoplasmic granules on the one hand, and micrococci on the other, an efficient means for their differentiation

All the glass apparatus and instruments used in the following examinations of dengue blood were sterilized by the following methods The cover-glass and microscope slides, which had never been previously used, were first washed in warm water with soap, then in clear water, then immersed in Seiler's cleansing fluid, prepared as follows

Bichromate potash	2 oz
Sulphuric acid	3 fld oz
Water	25 fld oz.

When they were taken from this solution, they were again washed in clear water, and finally heated in the flame of a spirit lamp just before they were used The metal instruments were washed in warm water and soap, clear water, and then in a 5 per cent solution of carbolic acid, they were also heated in the flame of the lamp just before they were used The platinum wire was fused to the end of a glass rod, this wire was sterilized always before using, by heating it to whiteness in the lamp The arm or finger of the person from whom the blood was obtained was washed with warm water and soap, then in a 5 per cent solution of carbolic acid

The part was then punctured with a sterilized needle, and a small portion of the blood which appeared at the point of puncture was transferred by means of the sterilized platinum wire to the sterilized cover glass, this was covered by another glass in order to obtain a thin layer of blood upon each of them, they were then separated, dried, and finally passed three times through the flame of the lamp, in order to thoroughly coagulate the albumen, and fix the blood elements

Blood for examination was obtained from about forty typical cases of dengue, at various times and places, and during the various stages of the disease The results which I obtained from examinations of these different specimens were entirely uniform

Dengue blood dried upon the cover glasses in the manner described was subjected to the action of certain chemical reagents, and aniline dyes, with the following results, viz. some were treated with a 10 per cent. solution of caustic potash, others with glacial acetic acid, and others with ether and chloroform. None of these chemical agents had any destructive effect upon the micrococci which the blood contained—they could be seen as brilliantly and distinctly after treatment as before.

A peculiar effect was produced upon the micro organism by the glacial acetic acid. This agent stained these organisms brownish, and changed their shape from spheres to ovoids; these were seen in such numbers that the field of the microscope was covered by them. I think this change in shape was only apparent, and was caused by the action of the acid upon the capsules of the cocci. I am sustained in this opinion by the fact that the organisms seem larger after treatment with the acid; this was due to the invisible capsule being made visible by this agent. Inasmuch as there are no tissue elements in normal or pathological blood, as corpuscles, granules, cells or cell elements, which can resist the destructive action of each of these chemical reagents, whilst bacteria, on the other hand, can resist them, it would seem evident that if spherical bodies, uniform in size, shape color and behavior, are found in the blood in certain pathological conditions, and these bodies can resist the destructive action of these chemicals, they must be micrococci, and cannot possibly be anything else. The remainder of these cover-glass preparations were subjected to the action of the various aniline dyes, in both weak and strong aqueous solutions, in aniline oil, water, and in alkaline solution.

The results which were obtained by these methods of staining were very instructive and important; for instance, it was shown:

First. That the dengue micrococci do not stain with the aniline dyes as readily as do other forms of bacteria.

Second. Methyl aniline blue in a weak solution of caustic potash furnishes a staining fluid for which the cocci of dengue manifest an especial affinity.

In order that the importance of this matter may be fully appreciated, I shall quote the following remarks from Friedlander:[1] "Furthermore, if among a certain number of elements which appear to be identical, some conduct themselves in a peculiar way toward a certain reagent, while others do not—if, for example, some are stained by a certain dye, while others remain colorless, we must necessarily conclude that there was a primary difference among the elements. Upon this principle are formed all the methods of preparation, and some of them very complicated, which are employed for the exhibition of the different histological elements. The principle in staining is, therefore, that certain elements or tissues, and also of cells, appropriate actively, or in large quantity, from the solution employed, a certain dye, and form with this a combination having an intense color, that is more or less permanent. Hence in many instances staining assumes the importance of a chemical reaction, by means of which any particular structure that lies concealed among other bodies, can be brought easily into prominence.

"This 'elective' action of dyes is of extreme importance in pathological investigations. The technique of dyeing is usually this: A section is transferred from distilled water to a dish filled with the staining solution, with which it is entirely covered; it remains in this for different lengths of time, varying from a few minutes to twenty four hours, and is again immersed in distilled water, in order to wash away the portions of the dye that are adherent to its exterior.

"In many cases, however, the section which has been removed from the staining solution, and washed, is subjected to further manipulation; it is again decolorized, that is, partially. In this instance there has occurred at first a diffuse, even, but unnecessary amount of staining; but during the supplementary process of extraction, while certain elements give up their staining completely, others, that have a stronger affinity for the dye, retain it. This is called by Ehrlich the principle of maximum staining. In accordance with these principles of staining, the blood, which had been dried upon the sterilized cover glasses, was submitted to the action of various aniline dyes, to find, if possible, some staining fluid with which isolated staining of the micrococci could be produced."

With this object in view, I tried successively Bismark brown, vesuvin, gentian, violet, methyl violet, fuchsin, methyl blue, aniline green, picro carmine, and eosin in watery solutions, and in solution with aniline waters. This result was obtained imperfectly with the solution of fuchsin in aniline water, and perfectly with methyl-blue in a solution of caustic potash.

With all the other dyes named, the results were negative, *e. g.*, all parts of the picture were stained alike—cells and organisms—and they were all decolorized with equal facility when washed in a 1 per cent. solution of acetic acid and then in absolute alcohol. With the methyl blue potash solution, however, a very different result was obtained; this dye, in the solution referred to, manifested such an affinity, or elective action for the organisms of dengue, that these would retain the blue color after this had been extracted from the blood cells by the decolorizing agents named.

The manner of preparing this solution, and the method of staining with it, which were adopted, are as follows: Concentrated alcoholic solution of methyl blue, 30 c. cm.; solution of caustic potash, 1 to 10,000, 100 c. cm. In a dish filled with this fluid the cover-glasses were floated, with their blood sides downward. The dish was then covered to exclude dust, and the cover-glasses were kept in this condition from twelve to twenty four hours. Better results are obtained by keeping the staining fluid during this time at the temperature of 100° F. The cover glasses are then removed from the staining solution and washed in the 1 per cent. solution of acetic acid, then in absolute alcohol, until the color is entirely or sufficiently removed.

---

[1] The Use of the Microscope in Clinical and Pathological Examinations. By Dr. Carl Friedländer. D. Appleton & Co. 1880.

I think a better picture is obtained, and the relative position of the organisms to the cells shown, if the process of extraction is arrested before the cells are entirely decolorized; they should then be mounted in Canada balsam, and examined with a high power, and with a large diaphram or open condensor. The blood cells should show of a faint blue color, whilst the micrococci, which are to be seen in the blood cells and plasma, will be stained an intense blue. The inability of these organisms to hold the other aniline dyes, acid or basic, to which they were exposed, their uniform size, their presence in the blood cells, their ability to resist the destructive action of acids, alkalies, ether, etc., it would seem are sufficiently distinctive to differentiate them from protoplasmic granules, or the products of cell disintegration. An additional reason for regarding them as micro organisms exists in the fact that they can and have been grown upon culture media, outside of the body.

In conducting these culture investigations, the same care to guard against error in results was practised as in the former. The test tubes, which had not previously been used for any purpose, were thoroughly washed with soap and water, then in clear water, dried, and plugged with absorbent cotton; they were then put into a furnace and exposed to a temperature of 400° F. for an hour. The culture medium which was used in all these investigations was that known as Miguel's lichen jelly; this was used in preference to gelatine, blood serum or other solid culture media for the following reasons:

It melts only between 55° and 60° C. (131° to 140° F.), which permits of the cultivation of such organisms as require for their development elevated temperatures. Ordinary nutritive gelatine melts before 30° C. (86° F.). Second. It remains without alteration or losing its power of solidifying when exposed to a temperature of 100° C. (230° F.) for rigerous sterilization. Gelatine, on the contrary, is reduced under such conditions to a turbid broth, which remains fluid on cooling. It is prepared by digesting Irish moss—*crispus chondrus*—in beef broth.

The broth is prepared as follows: Allow sixteen ounces of lean beef, as fresh as possible, two quarts of water, and sixteen grs. of table salt, to simmer for four hours in an uncovered vessel, then close it and boil for an hour, cool, and skim off the fat, neutralize carefully with carbonate of soda and filter.

In preparing the jelly, one ounce of Irish moss was digested in one quart of the broth, at a temperature short of boiling, the resulting decoction was passed through a colander to separate the swollen leaves, and then filtered through sterilized bolting cloth. It was then boiled for an hour, and whilst at this temperature the test tubes were filled with this jelly, by means of a sterilized pipette, to about half their capacity; cotton stoppers were then introduced in the tubes, and these were subjected to a temperature of 212° F. in a Koch and Grafiky sterilizing cylinder for an hour each day for seven successive days.

After the last heating, the tubes were placed at an angle whilst the jelly cooled, in order that as large a surface as possible should be presented upon which the organisms could grow and multiply. Many test tubes were sterilized and filled with the jelly, and subsequently subjected daily to the temperature of boiling water in the manner above described. These were carried to the homes of those persons from whom dengue blood was obtained for inoculation purposes.

In obtaining this blood, every possible danger of introducing germs by accidental means was guarded against. The method of washing the arm and sterilizing the needle with which the puncture was made, has been described. A small wire of platinum, fused to the end of a glass rod, was used to convey a small quantity of the blood which appeared at the point of puncture into the test tubes, where the point was brought in contact with the surface of the jelly. The only chance of introducing air germs occurred during the short time the cotton plug was removed to allow the passage of the platinum wire; the wire, of course, was heated to whiteness just before its use. Some twenty tubes of jelly were directly inoculated with the blood of dengue subjects; the blood used was obtained from different individuals, and always at their homes. These tubes were then put into an incubator, where the temperature was maintained constantly at 100° F., for the growth of the dengue organisms.

Without a single exception every tube which had been inoculated in the manner described showed, upon the surface of the jelly at the point of inoculation, a white spot elevated above the surface of the jelly; this gradually enlarged and could be seen, faintly outlined in the jelly, at the expiration of twenty-four hours. When this growth was examined under the microscope, with a high power, it invariably showed a pure culture of micrococci—which in color, size, shape and behavior, were identical with those seen in the blood of dengue subjects.

The uniformity of these results, in all the tubes inoculated, in growing these micrococci, and never other forms of bacteria, would certainly indicate that the matters of inoculation came from a common source, *e. g.*, the blood. If they had been accidentally inoculated from the air, or by the platinum wire, or through want of absolute sterilization of the tubes, many other forms of bacteria and fungi would have been found growing on the jelly, and these tubes, when opened, would have had the odor of putrefaction, which was not present in any of them. These cultures were continued from test tube to test tube for a period of six months. The method of perpetuating these pure cultures of the dengue micrococci, was to inoculate in the manner described, the sterilized jelly, in a fresh tube, from one which had previously been inoculated from the blood, then a third tube from the second, a fourth from the third, etc., through many generations of the organisms.

When it is considered that these culture investigations occupied a period of six months, and that during this time many transfers occurred from test tubes containing micrococci to those which did not contain them; that each transfer removed by generations the organisms from those contained in preceding tubes; that frequent microscopic examinations of the different series of tubes invariably revealed a pure culture, e. g., without any other forms of bacteria, it would seem that the methods of sterilization employed had been successful in excluding alien germs, and that those found had a common origin from dengue blood.

The life history of these organisms was watched daily, and studied by means of Holman's life-slide. In the old cultures, those which were removed by many generations from the blood, the organisms were smaller, less deeply colored, and less frequently encapsulated, than those seen in the blood, or removed from it by a few generations. When examined in water without being stained, or in other fluid media which possess a low index of refraction, the micrococci are seen in active movement (Brown movement).

In those cultures which are removed by only a few generations from the blood, the cocci are seen surrounded by capsules. These are sometimes faintly colored pinkish, and can be distinguished from the cocci, which possess a deeper color.

Two methods of generation were observed. The first by fission, the organisms are seen to divide through their centres, each coccus will thus form two others. Frequently these newly formed organisms remain united together so as to assume the form of a rod or chaplet, this indicates that they belong to the class named streptococci. In other cases they unite to form swarms or zoogloæ. These latter become more compact, the distinctions of the cocci less, the color of the mass deeper, until they finally contract into corpuscular bodies, about the size of red blood cells, these often unite to form filaments, which frequently assume the shape of a network. This I have often seen when the culture was thinned with distilled water and allowed to dry upon a microscopic slide. This arrangement can be seen, whether the specimens are stained or not. The swarms and chaplets of the micrococci can be much better seen in the stained preparations. A histological stand, Abbé's illuminating apparatus and $\frac{1}{12}$ H. I. objective, manufactured by J. Grunow, of New York, were used in these researches.

The results obtained in the following and last series of investigations of dengue blood are to me very satisfactory and conclusive, inasmuch as the means adopted to exclude alien germs were, as far as I can see, absolutely perfect.

The apparatus used consisted of a series of glass bulbs united and blown upon a capillary glass tube—Liebig's potash bulbs. To one end of this apparatus was attached a new hypodermic needle, by means of a short piece of new rubber tubing. To the other end of the glass tube (which was packed with cotton) was attached an aspirator.

The following is the method used in sterilizing and using this apparatus, viz. The series of bulbs were first chemically cleaned, one end of the tube was then packed with absorbent cotton, and the bulb heated in a furnace for an hour at 400° F. The rubber tubing, with the hypodermic needle attached, was treated with a 20 per cent. solution of carbolic acid, washed in clear water, and exposed to the temperature of escaping steam for an hour, in the sterilizing cylinder. It was then dried in the furnace, the free end of the tubing slipped over the free end of the glass tube, and the end to which the hypodermic needle was attached was encased with a sterilized test tube, this was held in its place and the needle protected from air germs by means of absorbent cotton, that was packed firmly in the mouth of the test tube, and around the needle. The entire apparatus as thus arranged, tubing and needle attached, and covered with test tube, was again put into the furnace and heated to 300° F. It was then removed from the furnace and carried to the home of the gentleman who kindly donated a sufficient amount of his blood for this investigation. He had a typical case of dengue. His arm was washed with soap and warm water, dried with a freshly ironed towel, and then a solution of carbolic acid, sufficiently strong to quickly whiten the skin, was applied to that part of the arm where the puncture was to be made. A ligature was then applied to the arm above the elbow. The test tube was removed from the hypodermic needle, and this was quickly passed into the large vein, at the bend of the arm. An aspirator was then attached to the free end of the glass tube—which was packed with sterilized cotton—and the bulbs partially filled with blood by means of aspiration. The glass tube, next to the rubber, was then closed and separated by the blow-pipe, before the needle was withdrawn from the arm.

These bulbs containing the dengue blood, which were effectually closed against the admission of all germs, and which contained no germs except those which entered with the blood from the veins of the donor, were then put into an incubator at 100° F. temperature, in order that a pure culture of the dengue micrococci might be grown in the bulbs, with their contained blood as the nutritive medium.

The first bulb was removed with the blow pipe, and examined at the expiration of six weeks. The blood was examined, first, directly, without admixture, second, after treatment with glacial acetic acid, undiluted and in weak solutions, third, with 10 per cent. solution of caustic potash and in weak solutions of this alkali, and fourth, finally subjected to the various aniline dyes, before referred to.

In the direct examinations, a small drop of blood was placed upon the cover glass, this was then inverted upon a slide, so as to obtain for examination a thin layer of blood, or the blood was examined in $\frac{2}{3}$ per cent. salt solution or a solution of osmic acid 1 to 300. In those specimens examined directly, the field appeared to be covered with blood cells and dark pigment granules, these latter were seen in immense numbers.

When the blood was examined in the salt solution, or in the solution of osmic acid—this latter fixed the cells, and by giving them a faint brown color, rendered them more distinct—it was seen that what appeared as dark pigment granules in the direct examination, was now recognized as dengue micro organisms, with all their distinctive features. The red cells in many cases were absolutely crowded with these, whilst in the plasma they were seen free, in swarms, zoogloea, masses, and in corpuscular bodies, which sometimes united to form filaments, as in the jelly culture Cover glass preparations of the blood, from this culture bulb, were subjected to the various aniline stains

The indisposition to hold any of these dyes, except the methyl blue potash, was as distinctly manifested as in the fresh dengue blood The only difference in the appearance of the micrococci as observed in the fresh blood and that obtained from the culture bulbs is this The organisms, when stained, appear larger in the latter than they did in the former, this, I think, is due to the fact that in the culture bulbs they are more frequently encapsulated When both cocci and capsule are stained, the size is apparently larger

The remaining bulbs were examined six weeks later They all contained pure cultures of the dengue streptococcus, with disintegrated blood cells These organisms were seen in zooglœa, swarms, and in compact corpuscular masses, these were often united to form filaments Normally shaped blood cells were found in only one of these last series of bulbs I think their preservation in this bulb was due to a layer of coagulated serum which had formed over the surface of its contained blood Many of the blood corpuscles in this bulb were more or less disintegrated, those which retained their shape were clouded by coagulation of the cell protoplasm, which concealed the organisms they contained to a greater or less extent These, however, could be seen in great numbers, when the blood was examined in a weak alkaline or acid solution, which rendered the cells more transparent None of the bulbs, when opened, had the least odor of putrefaction, and the only micro-organisms which they contained were those peculiar to dengue

Pure cultures of these were found in each of the series of bulbs, and were seen in their various stages of development, *e g*, with and without capsules, in swarms, in zooglœa masses and in corpuscular shaped bodies, frequently united to form variously shaped filaments In these filaments the corpuscular masses, and often the cocci which formed them, could be seen faintly outlined

This ends, at least for the present, these investigations No one better knows than myself the incompleteness of this work, nor appreciates better the possibilities which might have resulted from its continued prosecution The want of time and facilities for its proper execution prevented me from undertaking any additional labors in this matter The investigations were undertaken without bias, and the conclusions arrived at are the result of careful, conscientious work Whether these conclusions are true or false must be decided by the future

I am greatly indebted to Dr R Munger, of San Antonio, Texas, for excellent micro photographs of dengue blood, obtained from the first culture bulb The zeal and patience displayed by him in this work are characteristic of the lover of science, while the excellent results obtained mark him as an expert in these matters Many efforts were made by him to photograph the specimens colored with methyl blue, success was attained only with those specimens which were stained after Sternberg's method for photographing micro organisms, viz

A drop of sulphuric acid was placed upon the blood dried upon the cover-glass, this was allowed to remain for a minute, and then washed off with distilled water The cover glass was then floated, blood side downward, upon the following solution, in a watch crystal, viz

Iodine	grms 3
Iodide of potassium	" 5
Distilled water	" 500

After a few minutes' exposure the preparation will be found to present a deep orange color, which gives the desired contrast in a photographic negative The micro photographs which he obtained from specimens stained by this method displayed the blood cells, in which appeared many micrococci, while zooglœa and swarms are seen in the blood plasma

In conclusion, I desire to express the regrets I feel in not being able to complete these investigations Zopf, Koch and others indicate among the questions to be answered in a thorough study of any bacteria, the following

1 Shape, size, color and details of structure, *e g*, flagella, peculiar envelope, etc Character and speed of movements

2 Character of natural habitat Artificial media best adapted to growth and reproduction Stages of development passed through Formation of zooglœa spores, filaments rods, cocci, "swarms" Conditions under which such formation occurs Character of colonies formed in firm culture media

3 Capability of producing fermentation, putrefaction Character of decomposition products, volatile and other, formed in various nourishing media

4 Behavior toward oxygen at normal and altered pressures Behavior toward other gases

5 Effects of various temperatures on movements, germination, etc

6 Behavior in relation to light (phototonic properties) Behavior toward electricity

7 Behavior toward antiseptics and poisons

8 Are the forms under investigation found in a diseased organ or tissue What is the effect of inoculating animals of different orders and species with pure cultures If *virulent*, can the *virulence* be attenuated by exposure to air, to antiseptics, to heat, or by repeated "fractional" cultures Under what conditions Does the inoculation of attenuated germs have a *cumulative* effect if repeated at short intervals Does one inoculation give immunity towards a second made with virulent microbes

It will be seen that the character of investigation indicated by these questions could only be carried out by persons possessed of an abundance of time and money, and a willingness to devote both to such labors, or under the auspices and at the expense of the State or Federal Government In view of the brilliant results already attained by such investigations, *i e*, the protection furnished, by inoculation with the attenuated microbes, against the following diseases, viz small pox, hydrophobia, anthrax, yellow fever,(?) hog typhus and chicken cholera, it would seem a wise, humane and economical policy on the part of the State or Federal Government to encourage, by money appropriation, such investigations Among the probabilities which such investigations promise may be reckoned the prevention of many, perhaps all, the epidemic and contagious diseases to which man is heir.

Pasteur has astonished the world with his protective inoculations. His latest and most wonderful achievement is the immunity from hydrophobia which he claims is secured by inoculations with the attenuated virus.

Not less remarkable are the reputed discoveries of the yellow fever cryptococcus by Dr. Freire, of Rio Janeiro, and Dr. Carmona, of Mexico, and the immunity secured by inoculation with these organisms, as claimed by these gentlemen.

Other diseases and their specific microbes, notably diphtheria and phthisis, are under investigation by experienced bacteriologists, and in this day of marvels, we may expect soon to hear that these also are brought under the controlling influence of vaccination.

In the light of this experience, I feel secure in prophesying that within the next decade, dengue and many other contagious and infectious diseases will be as certainly prevented by inoculation as small pox now is. It remains to be seen what contribution of knowledge will be furnished by America to this promising system of preventive medicine.

MANAGEMENT OF THE SECUNDINES[1]

BY WM. H. WATHEN, M.D.,

PROFESSOR OF OBSTETRICS AND DISEASES OF WOMEN AND CHILDREN IN THE KENTUCKY SCHOOL OF MEDICINE, LOUISVILLE; GYNECOLOGIST TO THE LOUISVILLE CITY HOSPITAL.

One year ago, at the meeting of the American Medical Association in New Orleans, I read a paper in this Section on the "Treatment of the Membranes in Abortion and in Labor," but I do not offer an apology for reading another to-day.

Authorities in medicine do not agree as to the management of the third stage of abortion or of labor, and the subject is being extensively discussed in this country and in Europe. At the meeting of the British Medical Association at Belfast, in 1885, it attracted the attention of distinguished physicians of England, who failed to agree in many respects as to the best mode of treatment.

Felsenreich, in the January, 1886, number of the *Wiener Klinik*, and the great French obstetrician, Professor Pajot, in the February number of the *Archives de Tocologie*, wrote exhaustive papers on this subject, the former advocating and the latter opposing expectation. Most physicians who leave the expulsion of the membranes to nature are willing to remove the placenta when it is expelled from the uterus, but there are some who refuse to do so when it lies loose in the vagina. There are many who believe expectation is pernicious, and who remove the membranes from the uterus by expression, after the Credé or Dublin fashion, or draw upon the cord or edge of the placenta, or if the membranes adhere introduce the fingers or a hand into the uterus and separate and remove them.

Nor is our profession agreed as to the mechanism of the separation of the membranes from the uterus. It is argued that it may result from contraction or reduction of the placental area of the uterus, causing a retro-placental clot at the centre or at the periphery of the placenta, which completes the separation; or from a relative inequality in the contractile or retractile powers of the placenta and membranes, causing a separation in the trabecular structures connecting the decidua serotina and decidua vera to the uterine musculature. Neither is there a settled conviction as to whether the separation of the membranes occurs during or after the expulsion of the child. In an excellent paper on the "Anatomy and Relations of the Uterus," etc., in the *Edinburgh Medical Journal* of 1884, by Dr. Freeland Barbour, and from the investigations of Dr. Engelmann and others, it appears conclusive that, when the placenta is well formed, the musculature of the uterus is united to a compact layer of the decidua vera, decidua reflexa, decidua serotina, and the chorion, by a spongy or trellis-like arrangement of enlarged uterine glands and connective tissue.

The chorion and the amnion are seldom firmly united, though the union becomes more intimate toward the end of pregnancy, but at term the amnion may sometimes be easily dissected from the placenta. In the separation of the membranes the fundi of the glands with ciliated epithelium remain attached to the uterus and develop into new mucous membrane.

The formation of the placenta begins about the end of the second month, and it increases in size until the end of pregnancy, but in the latter months the union between the placenta and uterus becomes less intimate. Until the formation of the placenta the embryo is surrounded by the amnion, the chorion, the decidua reflexa, decidua vera, and decidua serotina. But the decidua vera and the decidua reflexa do not unite for several months after conception, and the amnion and the chorion are not in direct contact until between the end of the third and the end of the fifth month. It is important to remember this, for the fœtus may be expelled in an unbroken sac at any time before the sixth month—possibly in the sixth month—the placenta and other membranes being retained. In these cases the amnion has not reached the placenta, or is so loosely attached that it separates easily, the umbilical vessels being torn between the amnion and the placenta without disturbing the integrity of the amniotic sac.

We will divide the subject into the treatment of the third stage in abortions before the beginning of the third month, then the treatment of the third stage in abortions from the end of the second month to the end of the seventh, and finally the treatment of the third stage in premature labor and in labor at term.

Nature separates and expels the membranes by contraction and retraction, the placenta presenting at the os and coming away edgeways. This fact can be demonstrated in nearly every case of labor by grasping the placenta in the hand as it is forced through the neck of the uterus. It is possible that in fundal implantations of the placenta, it may sometimes present by its fœtal or amniotic surface with its long diameter in the os, or pulling on the cord may so invert the placenta as to cause the same abnormality

---

[1] Read in the Section on Obstetrics of the American Medical Association at St. Louis, May 4, 1886.

Hæmorrhage in the third stage of labor at any period of pregnancy is controlled by physiological contraction and retraction, and by the formation of trombi, or fibrinous coagula in the torn ends of the utero placental vessels, which is favored by contraction of the muscular fasciculi, which surround the vessels and contract their caliber

In abortion after the eighth week, in premature labor, and in labor, the membranes should be removed, whether separated or adherent, when they are not expelled within twenty to thirty minutes, and they should be removed sooner if we are not apprehensive of hæmorrhage, retention of the placenta, or of irregular contractions of the uterus If, in abortion, the woman shows symptoms of exhaustion or syncope, and bleeding continues, the shock in removing the membranes is not greater than that of tamponing the vagina

In the statistics of Dr Weir, of Copenhagen, expectation was followed by the retention of the decidual membranes in 1 78 per cent of cases, while in expression the per cent was 2 3 But in all other respects the results favor the immediate removal Post partum hæmorrhage occurred in expectation in 5 78 per cent of cases, and in expression the per cent was 2 3 In expectation manual removal of the placenta was necessary in 1 33 per cent of cases, and in expression in 64 per cent Secondary hæmorrhage followed expectation in 77 per cent of cases, and expression in 32 per cent

Mr T M Watt (Hovingham) in a large experience has seen no cases of post-partum hæmorrhage except in patients treated by expectation

James P Nevin, of Ballymoney, in over 200 midwifery cases saw but one case of post-partum hæmorrhage, that occurred in a patient where a midwife had allowed the placenta to be retained three hours, the woman died

Prof Pajot's statistics show that in 68 cases of retained placenta, which were left to nature, sixty resulted fatally, and in 102 similar cases, where the placenta was removed artificially and timely, only four died, though some of them were in extreme exhaustion from hæmorrhage when the operation was done

So long as a retained placenta is in the uterus or vagina the life of the woman is in jeopardy, and she may at any time be attacked with profuse hæmorrhage, septicæmia, and pelvic cellular or peritoneal inflammation When she has apparently recovered a placental or fibrinous polypus may form in the uterus, or she may suffer from subinvolution, hyperplasia etc Several women in Louisville have died within a few years from septicæmia, with pelvic peritoneal and cellular inflammation, or hæmorrhage, caused by a retained placenta

It may be urged that puerperal septicæmia is always exogenetic in its origin, but we know that a decomposed retained placenta is a prolific cause of the disease, and that its removal or disinfection is the only rational treatment In abortions before the end of the second month, if hæmorrhage ceases, no effort should be made to remove the membranes, unless they protrude into the vagina and can be taken away without introducing the fingers or instruments into the uterus These little membranes are generally innocuous, and will be separated and expelled without causing dangerous complications But if pregnancy has continued until a placenta has formed, expectation should not be practiced If in abortions after the second month the placenta is not expelled in twenty or thirty minutes, it should be removed, unless the woman is threatened with collapse or syncope from hæmorrhage, and when, from the absence of arterial pressure, hæmorrhage has stopped We may then wait until she has recovered from shock, or until there is decomposition of the membranes, or a recurrence of hæmorrhage

If the operation is done without delay the os will usually be dilated or dilatable, and a finger or fingers may be easily introduced into the uterus There is no instrument that can be substituted for the fingers, though it may sometimes be necessary to use other means to dilate the os Tents should, if possible, be avoided, and if the os cannot be dilated with the fingers, Ellinger's dilator, or my modification of Leanard's dilator, or Molesworth's dilator may be used The operation is seldom difficult, and with the patient anæsthetized, any part of, or the entire hand, may be introduced into the vagina, enabling us to examine all the uterine cavity with the fingers and to remove every part of the placenta and membrane Hæmorrhage will then stop, and there will probably be no other untoward symptom Of course our hands should be thoroughly disinfected, but this should be done in every case of delivery In premature labor and in labor at term, the placenta is more easily separated than in the earlier months, and is less frequently retained I fail to recognize a single fact to justify expectation in the management of the third stage of labor in the latter months of pregnancy, and while I do not believe it usually necessary to supplement or supplant nature in an effort to remove the membranes immediately after the child is born, I do not think the placenta should be left in the uterus more than twenty to thirty minutes, and it should be removed from the vagina immediately

The membrane can generally be removed by judicious expression during labor pains, but if this fail we may assist expression by introducing some fingers into the vagina and gently drawing upon the end of the folded placenta With a reasonable degree of care this treatment would neither cause septicæmia nor invert the uterus, and such accidents could only result from criminal ignorance or carelessness in the physician Unless uterine inertia follows the birth of the child there is no necessity for attempting expression until the uterus contracts in an effort to expel the placenta We should then follow the Crede method, being careful to express only during a contraction But it is always safe treatment to keep a hand over the uterus to see that it does not relax, and to encourage it to contract by kneading, massage, or expression, if it fail to do so otherwise

Credé reports that he removes the membranes in four and one half minutes after the child is borne with universally gratifying results, and Garrigues has also removed them in from ten to twenty minutes in 400 or 500 cases with excellent results But it is better to give more time for the membranes to separate and for coagula to form in the mouths of the vessels A little delay will do no harm, and will be less frequently followed by retention of decidual shreds If the placenta cannot be separated by expression then it should be separated carefully by a hand introduced into the uterus If the membranes are imprisoned in the uterus by contraction of the circular fibers of its lower segment or in its entirety, the neck should be dilated with the fingers, and the placenta separated and removed We should always have a hypodermic syringe charged with ergot for any emergency, but I no not believe that ergot should be given until the membranes are expelled

DISCUSSION

Dr Fuller, of Maine, after an experience of thirty-eight years, was in favor of prompt placental delivery, and congratulated the author of the paper upon his method of managing the secundines, and hoped that he would continue in his opposition to expectation He is usually able to express the placenta in cases of labor at term within five minutes after the expulsion of the child

In abortions the membranes can not be gotten away so readily, but they should be removed as soon as possible

Dr Willis P King, of Sedalia, Missouri, had seen 719 cases of labor at term and an unusually large number of abortions He removed the placenta promptly both in labor and in abortion, at term by Credé's method of expression, and in abortion, if the os is contracted, he practiced rapid dilatation with the finger or steel dilators When the finger, hand, or instruments were introduced into the uterus, and in lacerations of the genital tract, he used hot intrauterine injections of a solution of corrosive sublimate (1 4000) He had not seen a case of septic infection for several years

Dr C R Reed, of Middleport, Ohio, believed in immediate delivery of the placenta In nineteen cases out of twenty he was able to deliver the placenta by Credé's method and traction within five minutes after the expulsion of the child

Dr W W Potter, of Buffalo, New York, said that the terms uterine massage and Crede's method were sometimes employed as synonyms Suprapubic pressure was not Credé's method Credé, in 1853, said that your fingers must be forced behind the *corpus uteri*, the thumb over the anterior wall, and the placenta must be expressed just as the stone of a cherry is pinched out He did not believe in traction on the cord, but when the traction is slight no harm usually results He called attention to numerous sequelæ of abortion, and to the importance of effecting early evacuation of the *cavum uteri*

Dr John Morris, of Baltimore, advised the early removal of the placenta He never allowed the placenta to remain longer than twenty minutes after the birth of the child He distinguished between abortions the result of natural processes, and those induced by medicines and instruments In induced abortions, it is necessary to practice rigid antisepsis, and the prognosis is less favorable In so called "natural" abortion antiseptics are seldom required, and intrauterine irrigation is certainly not indicated He never gave ergot before the uterine cavity was emptied except in cases of "bleeders"

Dr French, of Minneapolis, desired to enter a protest against the indiscriminate use of intrauterine irrigation He had recently observed a fatal termination of a case in which the uterine cavity had been irrigated He now swabs out the *cavum uteri* when indicated with a mixture of iodoform, carbolic acid, and glycerine He had seen bad results follow vaginal irrigation with a corrosive sublimate solution, (1 2000) It was necessary to employ bichloride of mercury with extreme caution—if at all

CORNEAL ULCERS[1]

BY J W THOMPSON, M D ,

OF ST PAUL MINN

I shall occupy as little time as possible with that material relating to corneal ulcers which you can find and read at your leisure in any standard work on diseases of the eye Such works are numerous, and I dare say each one of you possesses one or more of them in your library, and that many of you are quite as conversant with the subject matter of them as I am They all relate nearly the same story, excepting little differences here and there of minor importance From them you have learned that ulceration of the cornea is the result of disturbed nutrition, and that this may be produced 1st, by a vitiated or improper state of the blood, 2d, by an irregular and deficient supply of the blood, 3d, by a disturbance or a loss of the nervous influence, and 4th, by an unnatural state of the cornea itself

It is especially rare, however, in practice to meet with cases that illustrate exclusively any of these pathological conditions except the one resulting from a disturbance or a loss of the nervous influence I have seen very meagre mention of this being assigned singly as a cause of the ulceration of the cornea in any of the numerous and well written text-books on the subject of ophthalmic surgery This may explain the fact that the nervous origin of corneal ulcers has been too frequently overlooked even by excellent observers But I think when the attention has been once directed to it, the symptoms are very plain, peculiar and characteristic, and will scarcely ever elude the attention of even a superficial observer The extent, occupying as I have seen it in a very few instances, the anterior surface of the globe and the conjunctival sac, the dusky, purplish appearance of the conjunctiva, the marked absence of the secretion, the dry and leathery appearance of the entire surface of the cornea, the absence of photophobia even when exposed to very bright light, the almost or quite complete anæsthesia of the cornea and the conjunctiva, and the entire absence of pain, form a picture the impression of which will scarcely be forgotten It is useless for me to speculate as to the exact nature and locality of the pathological conditions that give rise to this lesion of the eye It is a fact pretty conclusively demonstrated by experimental physiology, that the removal of the superior cervical sympathetic ganglion produces disturbance of the nutrition of the eye, and especially of the cornea But whether it be through the direct influence of the sympathetic or whether it be through the loss of the action of this nerve on the fifth or the trifacial, has not been very clearly determined It is, however, a well established fact that a division of the fifth does produce a very decided disturbance of the nutrition of the cornea, and the entire conjunctival sac

---

[1] Read before the Chippewa Valley Medical and Surgical Association at Eau Claire, Wis May 11 1886

In the case that I will relate I was unable to trace the origin of the nervous disturbance beyond the fifth, or tri-facial, since the case had been under progress for several days before my advice was sought I have selected this case out of the few that I have had an opportunity of seeing, because it is typical and furnishes a more pure and uncomplicated illustration of nervous disturbance in the production of corneal ulceration than any other that ever came under my observation The patient was a blacksmith by occupation, about 50 years of age For a period of nearly thirty years he had been a very industrious laborer, and all this time he had scarcely known a day of illness prior to the affliction for which he sought my advice He related that about a fortnight since, after a disturbed and restless sleep, he awakened in the morning with a pain in the left temple and side of the face, and slight dizziness He went to his shop, however, and continued to work uninterruptedly through the entire day The pain during the day became more tolerant at times, and he thought it to be only an ordinary attack of neuralgia, and that it would pass away under the influence of some domestic remedies which he would employ in the evening The next morning there was, in addition to the pain, a prickling sensation, and the dizziness was somewhat increased He felt some alarm about his condition, and sought the advice of his family physician, who gave the case a pretty thorough examination, and concluded that if it was neuralgia it was a very extraordinary case

In short, his symptoms continued to grow more alarming, and he soon began to observe some circumcorneal injection of the left eye, which was at first somewhat sensitive to the light This, with some slight increase, remained several days To follow his description, as the dizziness increased the pain diminished, and the face drew to the right side The facial paralysis was complete both as to motion and sensation The vision of the left eye began to be hazy The haziness increased rapidly, and when he consulted me he was scarcely able, with this eye, to determine the location of the window in my office The ocular tunic was quite vascular, with a considerable amount of chemosis about the cornea The entire conjunctiva presented a dry, glossy, purplish appearance The cornea was dry, leathery and nearly opaque In the centre there was a superficial ulcer with sharp, well defined edges There was entire absence of pain, and the anæsthesia was so complete that the finger could be rubbed all around in the conjunctival sac and over the cornea without producing any discomfort There was complete anæsthesia of all the parts supplied by the cutaneous nerves of the ophthalmic division of the fifth Of course, the affection of the eye for which he especially consulted me was quite beyond the resources of any known means of relief The destruction of vision in this eye became complete in a few days The paralysis, shortly after I saw the case, suddenly extended to other parts of the body, and soon terminated fatally An autopsy could not be obtained, and therefore the nature and origin of the brain lesion was left somewhat a subject of speculation

In connection with ulcers of the cornea I wish to call the attention of the profession to the use of a certain astringent, not for the purpose of extolling it but rather for the purpose of condemning it, and my experience with it teaches me that I cannot condemn it in terms too severely It is an astringent too that is recommended promiscuously in every form of conjunctivitis by all the modern works on diseases of the eye that I have been able to consult It is an old remedy and perhaps one of the most reliable astringents in the materia medica There is, perhaps, not a writer on this subject who has not spoken of it in terms of praise in conjunctivitis I have treated a great many cases of conjunctivitis, and it was a very common practice for me to combine this astringent with other astringents I regarded it as one of the safest and most reliable remedies that could be applied to an inflamed conjunctiva. Had it not been for a custom that I long since adopted in my ophthalmic practice of keeping a pretty complete record of my cases, I should, perhaps, have been employing the same old astringent to day with all the evil results it is capable of producing In all cases of conjunctivitis it is a very common custom to inspect the cornea closely before prescribing an astringent I was many times chagrined that within twenty four or forty eight hours after I had prescribed an astringent for a simple conjunctivitis, to find in the periphery of the cornea one or more minute ulcers It did not seem possible that they could have escaped my detection the day before There seemed to be something wrong, and I determined if possible to learn the cause I consulted my records very carefully and discovered that no case of ulceration had occurred in any of my cases of conjunctivitis where a simple astringent had been employed without alum, and that in every case where ulceration followed, alum had been prescribed singly or in combination with some of the other sulphates This seemed evidently the key-note to the ulceration I at once procured the fresh cornea of a hog's eye, cut it into small pieces and immersed them in a solution of alum of various strengths, and in every instance, at the end of twenty four or thirty-six hours, I found all the cementum of the cornea dissolved and nothing but the stroma and the anterior and the posterior elastic lamina remaining I have verified this a number of times

I have long since discarded alum, and ulcerations of the cornea in conjunctivitis have ceased to annoy me In those cases in which alum had been used without producing ulceration, the anterior elastic lamina had been intact, but if there had existed a minute break in the covering and the alum had had a free access to the proper substance of the cornea, it had invariably formed an ulcer Every valuable text-book on ophthalmology that I have been able to consult, recommends alum in high terms not only in simple conjunctivitis, but also in purulent and gonorrhœal This statement in regard to the action of alum may seem a little incredible to some, but I only ask them to subject it to a fair, impartial test, and I have no hesitancy in saying that their infidelity will be cured, and alum will no longer find a place in their ophthalmic therapeutics[1]

Herpes of the cornea frequently degenerates into chronic ulcers When this occurs in a child it is a very common practice to charge it to the account of scrofula or a scrofulous taint, and if the child should be a healthy subject, it is said to be due to a latent scrofulous predisposition The fact is, herpes that so frequently degenerates into small corneal ulcers is, as a rule, "not the localization of a blood disease," but rather the scrofulous appearances are the result of the herpes and ulceration The enlargement of the concatenated glands of the neck are, in a majority of cases, nothing more nor less than a reflection from the ulceration, just as a "felon on the finger may produce an enlargement of the axillary glands" These little cavities or ulcers formed from the degeneration of the herpes, under a proper treatment, fill up with transparent cornea, and every trace of them may be lost Sometimes the newly formed corneal tissue is cloudy at first, but subsequently clears and becomes entirely transparent Occasionally, however, I have seen them fill with a kind of chalky material that becomes a fixture and remains through life

Pathology teaches that in the healing of corneal ulcers new cells must be formed to take the place of those that have been detached and destroyed It has been somewhat conclusively shown that the new cells are derived from a finely granular blastema which changes into protoplasm, and that in this protoplasm new cells arise by a process of free cell formation "Again, Alexander Rollett maintains that this corneal protoplasm is contractile He arrives at this conclusion by experiments upon the fresh cornea of a frog He submitted it to the action of electrical currents Before the passage of the current the corneal tissue seems to be homogeneous, or with only a few radiated corneal corpuscles scattered through it Immediately after the excitation, elongated and sinuous, fusiform, elliptical, and round, clear figures make their appearance These are nothing but the optical expression of longitudinal, oblique or transverse sections of the communicating system of lacunæ traversing the cornea, the dilated nodal points of which are occupied by the nucleated, central portion of the radiating and contractile corneal corpuscles The contours of this canalicular system are rendered visible by the electrical current, because it occasions the retraction of the corneal corpuscles from the walls of the cavities in which they are contained In all such cases the nucleated masses of protoplasm may be seen surrounded by a transparent area, and with small spikes projecting from its surface, which are the retracted arms The appearances described vanish if the shock is not repeated They can, however, be made to appear again if the current is retransmitted"

309 Wabasha St , cor 3d, St Paul, Minn

MEDICAL PROGRESS

Electrolysis in the Treatment of Stricture—At the meeting of the Royal Medical and Chirurgical Society on May 25, Dr W E Steavenson and Mr W Bruce Clarke read a paper on this subject The more extensive use made of electrolysis in surgery and gynæcology abroad, and especially its successful employment in the treatment of stricture of the urethra, had induced the authors to undertake a series of observations to test the accuracy of the reports which had reached this country Their results bore out in every particular the results of success they had received from America Electricity, on account of its power of splitting up compounds into their chemical elements, could be used as a substitute for ordinary caustics to the human body It could be used with especial advantage to parts difficult of access, such as the male urethra and the uterine cervical canal, and it could also be applied to these and other regions where the application of other caustics was attended with a certain amount of danger Its effects could be limited to the points touched by the electrode The caustic effect could be arrested, or not commenced until the applicator, in the form of the electrode, was *in situ*, and the duration and extent of the caustic action were entirely under the control of the will of the operator The treatment of stricture of the urethra by this method was the most simple, and perhaps the most striking in its results, and had, therefore, been selected as the first on which to collect and report observations In this paper, the details were given of six cases of stricture of the urethra treated by electrolysis, the *modus operandi* was explained, the steps of the operation were given, and the advantages of this method of procedure were summed up There was usually no bleeding If hæmorrhage did occur, it was accidental, and usually showed that too strong a current had been used, no anæsthetic was required If pain or discomfort were produced, it was trifling The patient could, in the case of slight strictures, pursue his ordinary occupation during the period of treatment No antiseptics were required, as the process itself was aseptic In the majority of cases, there was no contraction or return of the stricture Eschars produced by caustic alkalies were said to heal with less contraction than wounds produced in any other, and electrolysis with the negative pole of a battery was a means of applying the same destructive action as was caused by the caustic alkalies to parts difficult of access in a way which was impossible by any other method Probably, other chemical decompositions and combinations took place at the negative pole besides those characteristic of the caustic alkalies, but they had not, up to the present time, been thoroughly made out

---

[1] Those who may have observed this peculiar action of alum on the cornea will confer a favor on the author by communicating the fact either by letter or otherwise

Mr Berkeley Hill was much interested by the paper, but was sorry to say that he could not find the conclusions of the authors quite satisfactory The cases had been related, after the manner of the American writers on this subject, without enough detail as to the size, nature, and position of the stricture One case had suffered from stricture, more or less for twenty years, he had often been relieved for a time by ordinary dilatation, and then had slowly relapsed The relief given by Dr Steavenson and Mr Bruce Clarke dated only from about eight months ago, and he expected that his discomforts would return, at any rate, at present, there was no proof of a cure It was universally admitted that, by patient pressure, a larger catheter could be passed, but he thought the authors had hardly made due allowance for this in their account of the increased size of the electrical bougies passed, which might perhaps be due to patience as much as electricity He had himself carefully considered the American cases that Dr Newman had published, and had followed his plan in treating one case of his own There was stricture two inches and a half from the meatus, probably behind an old urethral abscess, he could see clearly with an endoscope, which he was sorry the authors had not used He passed a needle, which formed one pole of the electric circuit, into the scar-tissue, and could see, with the endoscope, that nothing more happened than the occasional liberation of a bubble The patient felt no pain at all, except on making and breaking the current, he measured the currents strength by the patient's feelings After fifteen minutes application of the current, he found the stricture enlarged from 19 to 20 of the French scale After further treatment, in the same manner, it gradually contracted from 20 to 16, and as cure semed very unlikely by such a process, he resorted to other methods, and found no difficulty in widening it

Mr F Swinford Edwards had treated a case, with the help of Dr Steavenson He had first seen the patient two and a half years ago, when he found three strictures, two penile and one subpubic, of size No 12 (French), these he gradually dilated to No 25 For two years, the patient was lost sight of, and then returned with three strictures, distant ½ inch, 4 inches, and 5½ inches from the meatus, admitting only No 4 (French) Dr Steavenson applied a No 3 electrode and current of from 5 to 8 milliamperes, this did not pass, but the flow of urine was improved, and a few days later, a bougie, No 10, could be passed, and, after a few weeks under electrical treat ment, a bougie No 26 steel or No 28 pewter, could be admitted Whether it was to be called strictly a cure or not, it was certainly satisfactory in enabling the patient to get about and to do his work, and his case was a bad one, which would otherwise have needed treatment with an Otis's dilating urethrotome He hoped the treatment would be further investigated in hospital cases

Mr G Buckston Browne thoroughly agreed that it would be a very good thing if the practised hands of the seniors in the profession could be brought to try this method, for there was hardly any point in which more experience was needed than in estimating and accurately diagnosing stricture He was inclined himself to attribute the results embodied in the paper to the dilatation, not to the electricity, else why was it found advisable to use gradually larger and larger electrodes? Even pressure, without passage of a catheter, often did much to facilitate the passage of urine He had considered Dr Newman's cases with some care, and could not help calling attention to one remarkable point in them, that they were, every one of them, successful

Dr Steavenson was not familiar with the endoscope which Mr Berkeley had shown In Mr Hill's cases, he understood there had been puncture, and he certainly was not surprised, that contraction had followed They had used bougies, of gradually increasing size, to keep in contact with the walls of the urethra

Mr Bruce Clarke said he had been quite prepared to meet the two chief objections that had been urged, that the cases were not really of organic stricture, and that they were not really cured As to cure, he was bound to admit that the operations had been performed last August, and not treated since, they were under observation, and had not relapsed, only time could prove their ultimate cure As to the point that they were spasmodic strictures, he could not admit it, in one of the cases, there had been extravasation of urine, at first, nothing could be introduced, but after electrical treatment, he could pass No 11 (English), and that was a success as great as any after a cutting operation

The British Medical Journal, also says editorially Interest in the subject was first aroused by one of the daring attempts of American surgery, made by Dr R Newman, of New York, who published, about eighteen months ago, *Tabular Statistics of 100 Cases of Urethral Stricture treated by Electrolysis, without Relapse* It would have appealed, perhaps, even more strongly to those who believe in the fallibility of human nature, if there had been one or two relapses The fashion of operating admits of many small variations, but the essential points are, that one pole of the battery shall be of metal, and in contact with the surface of the stricture, and the other widely spread out by means of a pad over a considerable surface of the body, the back or elsewhere, and that between these poles a current of considerable strength should be passed It is found most successful and least uncomfortable that the negative pole should be in contact with the urethra, the positive, with the body A current may be passed which is strong enough to act upon the stricture without giving any discomfort, except, perhaps, at the moments of making and breaking What the exact action of the current upon the cicatricial tissue may be, we are hardly in a position to say, though the actual watching of the process by means of an endoscope, as practised once by Mr Berkeley Hill, may throw more light upon it It is covered, at present, by the word "electrolysis," of which, when applied to fibrous tissues, we must admit that the limits are somewhat indistinct At any rate, it is alleged that not only does the resistance of the stricture give way, but that more or less of the tissue which forms it is turned into a slimy mass of broken down epithelium, and so disappears, *without leaving a contracting cicatrix* The *à priori* impression is certainly strong that, where tissue has disappeared, there must be a cicatrix, and that, if there is a cicatrix, it must contract sooner or later Those who have practised electrolysis will gain a much more attentive hearing and a more zealous following when they can show a longer maintenance of good results than the eight months which have elapsed since Mr Bruce Clark's operations When the malady is chronic, it naturally needs a long time to judge of the cure, but, at the same time, the habits of scars, due to different causes, are known to vary greatly in contraction, and it is possible enough that there may be less contraction after electrical action than any other, even than those from caustic alkalies And, further, we are not yet experienced enough to assert how completely similar or dissimilar to an ordinary cicatrix this process of electrolysis may be That it deserves trial from the older and most skilled hands, there would seem to us little doubt, and we can imagine it most convenient that the electrical necessaries should be managed by the younger students of that somewhat difficult class of instruments

BERI-BERI —An industrous investigation of some of the circulatory conditions that obtain in the Japanese "kakké" or beri-beri has been undertaken by DR WALLACE TAYLOR, with the production of some valuable results In none of the cases was there organic disease of the heart or arteries, and no functional derangement other than that attributed to the influence of the "kakké" Sphygmographic tracings revealed a very sudden and high upstroke, with precipitous descent from the apex of the percussion wave and marked dicrotism The first deviation of the circulatory system in kakké from the normal is one of cardiac excitement There is also diminished tension, due to loss of arterial tone The chief causes of danger in the acute disease are found in the impaired condition of the heart and enfeebled circulation The extent, however, to which the heart and vaso-motor system are affected in the disease is liable to relatively large changes Dr Taylor considers that all the conditions of the heart and arteries can be explained by the action of the *materies morbi* of kakké upon certain portions of the cerebro spinal nerves and sympathetic system Age exercises considerable influence over the occurrence of the disease, which is most common between 16 and 28 years of age One attack of kakké appears to render the patient more liable to subsequent affection Women are much less likely to be affected than men Though the female sex in general enjoy a marked immunity, yet in the puerperal state they are very liable to take the disease It is but seldom that traces of albumen are found in the urine Partial paralysis of the muscular walls of the bladder is occasionally to be met with No mention is made of the multiple neuritis, of which so much has lately been written in England —*Lancet*, May 8, 1886

PARALYSIS OF LARYNGEAL MUSCLES —The generalization so strongly upheld by DR FELIX SEMON, that the abductor muscles of the larynx are more prone to paralysis than the adductors does not carry us a great way, but it is very useful as a step to further knowledge, A general cause acting on the recurrent laryngeal nerves appears always to paralyze or weaken the abductor muscles before or more than the adductor M Charazac records a case in the *Revue Mensuelle de Laryngologie* of cystic goitre associated with unilateral paralysis of the adductor muscles of the larynx consecutive to compression of the right recurrent laryngeal nerve During expiration the larynx appeared to be perfectly healthy, the vocal cords left the middle line in a natural manner, so that the glottis presented its normal triangular outline But during phonation the left vocal cord closed up to the mesial line in good form, but the right did not approach its fellow We think M Charazac lays too much stress on his single observation, supposing that to have been a true one, and not to be explained by other causes than the one to which it is attributed So far the generalization to which we above referred seems to have been confirmed and strengthened by numerous and carefully observed cases —*Lancet*, May 22, 1886

FALSE JOINT FROM A FRACTURE IN INFANCY —M BERGER recently showed a very interesting specimen at a meeting of the Sociéte de Chirurgie of Paris It consisted of the lower limb of a man 57 years of age, who had received a fracture of both bones of the leg when only nine months old This was followed by the formation of a false joint which prevented the man from walking The upper fragments of the tibia, and fibula were rounded off, and fitted into cup-like depressions on the lower fragments The adjacent surfaces were eburnated and coated with dense granulation tissue (not cartilage), and were held together by a capsular ligament continuous with the periosteum and lined by a true synovial membrane The knee and ankle were not ankylosed, as is often the case in such conditions The whole limb was undeveloped, as the following measurements on the two sides show Length of foot 18 centim as compared with 24 centim , length of patella 5 0 centim , instead of 6 0 centim , length of femur 36 centim , as against 39 centim The muscles were not degenerated, the nerves to the naked eye were healthy, but the skin over the toes was the seat of anæsthesia and local asphyxia. The question raised by M Berger was, whether these developmental changes were the results of the "false joint," or whether they and it were both due to one obscure trophic affection —*Lancet*, May 8, 1886

THE
Journal of the American Medical Association
PUBLISHED WEEKLY

THE EDITOR OF THIS JOURNAL would be glad to receive any items of general interest in regard to local events or matters that it is desirable to call to the attention of the profession Letters written for publication or containing items of information should be accompanied by the writer's full name and address, although not necessarily to be published All communications in regard to editorial work should be addressed to the Editor

THE BLOOD PLAQUES AND COAGULATION

In the last number of THE JOURNAL we attempted to give some idea of the blood-plaque, and showed that while there is very strong evidence that it is an independent element of the blood, there are also strong reasons for believing that it is what Hayem terms an hæmotoblast, or young red corpuscle But which of the theories be held matters but little in considering the relation of the plaque to the process of coagulation This however, is best prefaced by some account of the histology of the formation of fibrin, and its relation to the histological elements of the blood, including the blood plaques

In the study of the formation of fibrin under the microscope it has long been noticed that the fibrin filaments spread out as rather distinct rays from the minute aggregations known as Schultze's granular masses This was noticed by Schultze, and by Ranvier in 1873, who regarded them as centres of coagulation, and also by Riess, Hayem, Leube, Bizzozero and others Ranvier, Davidson, Bizzozero and Halla think that there is a distinct and direct connection between the fibrin-threads and the granular masses but Schultze thinks that the threads do not proceed from the masses, but pass over or through them Heyl, having observed that in Bizzozero's fluid the number of granular masses increases as the leucocytes decrease, and that both the granular masses and leucocytes stain with methyl violet, has drawn the unwarranted conclusion that, on the assumption that the leucocytes break down during coagulation, the granular masses are derived from the leucocytes This view has received the support of Hlava and Riess, but is denied emphatically by Osler and Laker, and Lowit, after a careful study of the coagulation of lymph under the microscope, has found nothing that can be regarded as leucocyte detritus The generally accepted view as to the granular masses, then, is that they are formed by the plaques

In the very careful study made by Kemp he found that the formation of the granular masses by the plaques may be seen in the following manner The finger is pricked and a good-sized drop of blood is squeezed out This is taken immediately upon a cover-slip, and then as quickly as possible most of it is washed off by a jet of a 75 per cent NaCl solution from a wash bottle The cover-slip is now placed on a slide, and transferred to the microscopic stage as quickly as possible The plaques have the property of sticking to the slip, while the other elements are easily washed away by the jet, so that upon examination the whole field will be seen to be filled with plaques, some of them isolated, but most of them grouped in masses consisting of from two or three to a dozen or more They are now not pale and homogeneous, with a symmetrical outline, but appear glistening and granular, and their contour, instead of being regularly oval or circular, has become jagged These changes are the more marked the longer the time which has elapsed before the preparation is observed, and they may be seen to take place step by step while the observer watches the preparation The plaques continue to undergo changes in form, until finally when they are grouped together only a granular mass is found, and the individual plaques can no longer be distinguished clearly "*Pari passu* with these changes processes are seen which run out from the granular masses, and when coagulation sets in these processes are nearly always found to be continuous with threads of fibrin The threads of fibrin are sometimes deposited as long needle-shaped crystalloids which are often seen lying free in the field, and not connected with the granular masses, but the greater number are formed most thickly around these masses, from which they often radiate as centres"

Kemp has found that when the blood-plasma is very much diluted but little fibrin is formed "Under these circumstances the field is comparatively clear, and it can then be seen that no fibrin proceeds from the leucocytes, but all comes from the plaques, or is deposited freely in the field" Hayem and Schimmelbusch have pointed out that fibrin may be formed elsewhere than around the plaques, and this view has been confirmed by Osler, though Bizzozero has stated that fibrin is deposited around the plaques and nowhere else Osler says in his third lecture that it may be noticed that fibrin appears quite independently of the plaques, particularly if healthy blood be examined in which plaques are not very numerous. When there is an abundant formation of fibrin the network of threads is seen all over the field, and every spot is full of fibrin, but when the fibrin is not abundant it will almost always be seen that the fibrin is thickest in the vicinity of the masses of plaques. "Even in preparations where the fibrin is sparingly formed, the threads are deposited elsewhere than around the granular masses, and occasionally, though rarely, I have found granular masses around which the fibrin did not appear to lie more thickly than in the clear field. The fact that nearly always the fibrin is deposited most thickly around the granular masses, even radiating from them as centres, while interesting and significant, is not conclusive proof that the plaques are connected with coagulation, for the same adhesive property of the plaques which makes them adhere to each other, may also cause the threads of fibrin to stick fast as they separate out from the medium around them. This seems all the more probable when we consider that the fibrin as well as the plaques is sticky and adheres to the glass" (Kemp). The fact that in preparations in which the clot is scanty the fibrin is deposited more thickly in the vicinity of the masses of plaques may possibly be due to the plaques giving up something which causes or hastens coagulation, and that in dilute solutions this substance is more abundant in the vicinity of the granular masses than elsewhere.

Laker has taken the ground that the fibrin-threads are folds of a membrane which he calls the primary fibrin membrane, a view almost identical with that taken by Virchow in 1856. Kemp concludes that what Laker describes as a membrane is a layer of the homogeneous substance described by Virchow, Rindfleisch and Hermann, which is essentially of the same composition as fibrin, and from which the fibrin threads are formed by a process very closely resembling crystallization, if not identical with it. Hermann thinks that the threads are formed by a process which closely resembles crystallization, and Schimmelbusch insists most positively that the formation of fibrin-threads is a true crystallization process, nor does he believe that there is a previous stage, either homogeneous or granular. Hayem, though not believing in the fibrinous character of the plaques, compares the formation of fibrin to a sort of crystallization starting from small crystals already formed. Kemp says: The definite form which the fibrin threads take, especially the typical needle shaped form of the threads when deposited isolated in scanty clot, speaks strongly in favor of a crystallization, while the subsequent toughening and contraction of the threads show a clear resemblance to the coagulation of certain proteids, notably myosin. In fact, it appears that we have in blood an interesting process which may be regarded as intermediate, in a certain sense, between a true crystallization on the one hand, and the coagulation of certain proteids, as myosin, etc., on the other. Hence Kemp thinks it evident that there is no histological connection between the plaques and fibrin, so that if the former are involved at all in coagulation the connection must be a chemical one, in other words, the plaques must give up something to the plasma at the same time that they break down. But the strongest evidence of a connection between the plaques and coagulation is derived from facts pointed out by Hayem, Bizzozero, Lavdovsky, Halla and Ferraro that fibrin is formed *pari passu* with the breaking down of the plaques, and that reagents or conditions which retard the breaking down of the plaques, retard to *precisely the same extent* the formation of fibrin, and reagents which *preserve the plaques prevent the formation of fibrin altogether*. Kemp's observations, so far as completed, confirm these facts in every respect.

The question now arises, what part do the plaques play in the process of coagulation? Hayem and Bizzozero think that their part is to furnish something essential to coagulation, and they agree that *ferment* is in all probability the agent in question. Now, in some experiments Kemp noticed that blood flowing through a dirty tube coagulated more quickly than in flowing through a clean glass tube, and he thinks that this would seem to show that in passing through the dirty tube the blood took up something which brought about coagulation before the plaques broke down, but which is also formed later by the plaques when they break down. And from what we know of coagulation at the present time, he says, it seems probable that the agent in fibrin-formation that would be more likely to act in this manner is the *ferment*. Osler has examined the relation of the blood-plaque to coagulation experimentally, and his results are very interesting. If an ordinary ligature, partly teased out, be passed through the femoral vein of a dog and allowed to remain for five or six minutes, or less, the threads become coated with the plaques, and the same coating of plaques may be obtained by whipping freshly drawn blood with a bunch of threads, as in Bizzozero's experiment. The threads are then carefully washed in a saline solution, by which the red corpuscles are removed. If the threads be then dipped into a coagulable solution clotting occurs

But Rauschenbach criticizes this experiment by saying that the threads may have absorbed ferment which was not washed away, and that the coagulable fluid used by Bizzozero is only a test for free ferment Kemp thinks that the first objection is valid, but Osler replies to it by saying that the chief elements in the clot are plaques, and the greater the number of the plaques the denser the coagulum To the second Kemp replies that by granting it we exclude the leucocytes adhering to the threads from a share in the formation of the ferment, if any is formed by what does adhere to the threads It then remains to explain why the time of coagulation should depend upon the number of plaques, and the experiment remains of value as offering strong support to the theory that the ferment may be derived from the plaques

But there is further and more conclusive evidence of the participation of the plaques in the process of coagulation, as afforded by the experimental production of thrombi So far as completed Kemp's work in this direction tends to confirm the results of Osler, Bizzozero, Hayem, Ferraro and Lubnitzky, who find that the white thrombus is not composed of leucocytes but of plaques, that is due to an agglomeration of plaques around a lesion in the vascular wall, or a foreign body introduced into the vessel The plaques are the elements which first settle on the edge of the wounded vessel, and form the basis of the clot, as shown by Eberth, though he still holds to the idea that the leucocytes play an important part in the formation of white thrombi Osler contends that they are composed chiefly of plaques, and that their further development results from the disintegration of the plaques, that a granular or stroma-fibrin and a fibrillar or plasma-fibrin must be recognized, the former being identical with Weigert's coagulation necrosis

The conclusions drawn by Kemp regarding the relation of plaques to coagulation are 1 When the blood is drawn the plaques break down almost immediately This is not true of any other element of the blood 2 The breaking down of the plaques is intimately connected, in times at least, with the clotting of the blood 3 The connection between the breaking down of the plaques and the coagulation of the blood is not histological, but chemical—*i e*, the plaques appear to give up a soluble substance which is active in coagulation 4 The active agent in question is most probably *fibrin-ferment* 5 Fibrin is deposited histologically independent of any of the cellular elements of the blood 6 When the clot is very scant fibrin is deposited as long, needle shaped, crystal-like bodies

"METAPHYSICIANS," "FAITH HEALERS," AND THE ILLINOIS PRACTICE ACT

The Illinois Practice Act is a law, coming under the police power of the State, and is maintained on the theory that the law is enacted for the preservation of the public health from the experiments of quacks and unqualified persons, and, says Attorney General McCartney, of Illinois, it must be construed as an absolute prohibition against the practice of medicine in this State, except under the conditions specified in the Act These conditions are that the person practising, if he practises under a diploma from a medical college—shall have a certificate from the Board of Health of the State that his diploma is genuine, or if he is not practising under a diploma, that he has been examined and found duly qualified by the State Board of Health, or that he is a commissioned surgeon of the United States Army or Navy, or that he had been practising medicine ten years in the State of Illinois prior to the first day of July, 1877, or that he was a student prescribing under the supervision of preceptors, or was performing gratuitous services in a case of emergency These are the conditions, and these alone, under which a person may "profess publicly to be a physician and to prescribe for the sick, or to append to his name the letters of M D"

Now what is it to practise medicine? Is it necessary that the person practising shall administer drugs, or that he shall perform a surgical operation? Would any court in the land limit the term to this definition? Does not "practising medicine" mean that the person practising professes to cure disease, or to assist in the cure of disease or bodily ailments? We may easily suppose the case (for such a one is on record) in which a distinguished consulting physician continues in practice for several years without prescribing a dose of medicine once in two years, or longer This man is certainly practising medicine And inasmuch as the "metaphysicians," "faith-healers" profess to cure disease and bodily ailments, and in some cases append the letters M D to their names, though signifying on their signs that they are "metaphysicians" or "faith-healers," are they not indictable under the Illinois Practice Act for practising medicine without licenses? At least one of these people has the letters M D appended to his name on his sign in Chicago From long custom the public understands that those letters mean Doctor of Medicine, though the person misappropriating them may say that they mean "Money Down," "Milk Diet," or "Medicine Disgusts"

The Secretary of the Illinois State Board of Health, in response to a question as to the legality of these that it may be noticed that fibrin appears quite independently of the plaques, particularly if healthy blood be examined in which plaques are not very numerous. When there is an abundant formation of fibrin the network of threads is seen all over the field, and every spot is full of fibrin, but when the fibrin is not abundant it will almost always be seen that the fibrin is thickest in the vicinity of the masses of plaques. "Even in preparations where the fibrin is sparingly formed, the threads are deposited elsewhere than around the granular masses, and occasionally, though rarely, I have found granular masses around which the fibrin did not appear to lie more thickly than in the clear field. The fact that nearly always the fibrin is deposited most thickly around the granular masses, even radiating from them as centres, while interesting and significant, is not conclusive proof that the plaques are connected with coagulation, for the same adhesive property of the plaques which makes them adhere to each other, may also cause the threads of fibrin to stick fast as they separate out from the medium around them. This seems all the more probable when we consider that the fibrin as well as the plaques is sticky and adheres to the glass" (Kemp). The fact that in preparations in which the clot is scanty the fibrin is deposited more thickly in the vicinity of the masses of plaques may possibly be due to the plaques giving up something which causes or hastens coagulation, and that in dilute solutions this substance is more abundant in the vicinity of the granular masses than elsewhere.

Laker has taken the ground that the fibrin threads are folds of a membrane which he calls the primary fibrin membrane, a view almost identical with that taken by Virchow in 1856. Kemp concludes that what Laker describes as a membrane is a layer of the homogeneous substance described by Virchow, Rindfleisch and Hermann, which is essentially of the same composition as fibrin, and from which the fibrin threads are formed by a process very closely resembling crystallization, if not identical with it. Hermann thinks that the threads are formed by a process which closely resembles crystallization, and Schimmelbusch insists most positively that the formation of fibrin-threads is a true crystallization process, nor does he believe that there is a previous stage, either homogeneous or granular. Hayem, though not believing in the fibrinous character of the plaques, compares the formation of fibrin to a sort of crystallization starting from small crystals already formed. Kemp says The definite form which the fibrin threads take, especially the typical needle shaped form of the threads when deposited isolated in scanty clot, speaks strongly in favor of a crystallization, while the subsequent toughening and contraction of the threads show a clear resemblance to the coagulation of certain proteids, notably myosin. In fact, it appears that we have in blood an interesting process which may be regarded as intermediate, in a certain sense, between a true crystallization on the one hand, and the coagulation of certain proteids, as myosin, etc, on the other. Hence Kemp thinks it evident that there is no histological connection between the plaques and fibrin, so that if the former are involved at all in coagulation the connection must be a chemical one, in other words, the plaques must give up something to the plasma at the same time that they break down. But the strongest evidence of a connection between the plaques and coagulation is derived from facts pointed out by Hayem, Bizzozero, Lavdovsky, Halla and Ferraro that fibrin is formed *pari passu* with the breaking down of the plaques, and that reagents or conditions which retard the breaking down of the plaques, retard to *precisely the same extent* the formation of fibrin, and reagents which *preserve the plaques prevent the formation of fibrin altogether*. Kemp's observations, so far as completed, confirm these facts in every respect.

The question now arises, what part do the plaques play in the process of coagulation? Hayem and Bizzozero think that their part is to furnish something essential to coagulation, and they agree that *ferment* is in all probability the agent in question. Now, in some experiments Kemp noticed that blood flowing through a dirty tube coagulated more quickly than in flowing through a clean glass tube, and he thinks that this would seem to show that in passing through the dirty tube the blood took up something which brought about coagulation before the plaques broke down, but which is also formed later by the plaques when they break down. And from what we know of coagulation at the present time, he says, it seems probable that the agent in fibrin formation that would be more likely to act in this manner is the *ferment*. Osler has examined the relation of the blood-plaque to coagulation experimentally, and his results are very interesting. If an ordinary ligature, partly teased out, be passed through the femoral vein of a dog and allowed to remain for five or six minutes, or less, the threads become coated with the plaques, and the same coating of plaques may be obtained by whipping freshly drawn blood with a bunch of threads, as in Bizzozero's experiment. The threads are then carefully washed in a saline solution, by which the red corpuscles are removed. If the threads be then dipped into a coagulable solution clotting occurs

But Rauschenbach criticizes this experiment by saying that the threads may have absorbed ferment which was not washed away, and that the coagulable fluid used by Bizzozero is only a test for free ferment Kemp thinks that the first objection is valid, but Osler replies to it by saying that the chief elements in the clot are plaques, and the greater the number of the plaques the denser the coagulum To the second Kemp replies that by granting it we exclude the leucocytes adhering to the threads from a share in the formation of the ferment, if any is formed by what does adhere to the threads It then remains to explain why the time of coagulation should depend upon the number of plaques, and the experiment remains of value as offering strong support to the theory that the ferment may be derived from the plaques

But there is further and more conclusive evidence of the participation of the plaques in the process of coagulation, as afforded by the experimental production of thrombi So far as completed Kemp's work in this direction tends to confirm the results of Osler, Bizzozero, Hayem, Ferraro and Lubnitzky, who find that the white thrombus is not composed of leucocytes but of plaques, that is due to an agglomeration of plaques around a lesion in the vascular wall, or a foreign body introduced into the vessel The plaques are the elements which first settle on the edge of the wounded vessel, and form the basis of the clot, as shown by Eberth, though he still holds to the idea that the leucocytes play an important part in the formation of white thrombi Osler contends that they are composed chiefly of plaques, and that their further development results from the disintegration of the plaques, that a granular or stroma-fibrin and a fibrillar or plasma fibrin must be recognized, the former being identical with Weigert's coagulation necrosis

The conclusions drawn by Kemp regarding the relation of plaques to coagulation are 1 When the blood is drawn the plaques break down almost immediately This is not true of any other element of the blood 2 The breaking down of the plaques is intimately connected, in times at least, with the clotting of the blood 3 The connection between the breaking down of the plaques and the coagulation of the blood is not histological, but chemical—*i e*, the plaques appear to give up a soluble substance which is active in coagulation 4 The active agent in question is most probably *fibrin-ferment* 5 Fibrin is deposited histologically independent of any of the cellular elements of the blood 6 When the clot is very scant fibrin is deposited as long, needle shaped, crystal-like bodies

"METAPHYSICIANS," "FAITH HEALERS," AND THE ILLINOIS PRACTICE ACT

The Illinois Practice Act is a law, coming under the police power of the State, and is maintained on the theory that the law is enacted for the preservation of the public health from the experiments of quacks and unqualified persons, and, says Attorney General McCartney, of Illinois, it must be construed as an absolute prohibition against the practice of medicine in this State, except under the conditions specified in the Act These conditions are that the person practising, if he practises under a diploma from a medical college—shall have a certificate from the Board of Health of the State that his diploma is genuine, or if he is not practising under a diploma, that he has been examined and found duly qualified by the State Board of Health, or that he is a commissioned surgeon of the United States Army or Navy, or that he had been practising medicine ten years in the State of Illinois prior to the first day of July, 1877, or that he was a student prescribing under the supervision of preceptors, or was performing gratuitous services in a case of emergency These are the conditions, and these alone, under which a person may "profess publicly to be a physician and to prescribe for the sick, or to append to his name the letters of M D"

Now what is it to practise medicine? Is it necessary that the person practising shall administer drugs, or that he shall perform a surgical operation? Would any court in the land limit the term to this definition? Does not "practising medicine" mean that the person practising professes to cure disease, or to assist in the cure of disease or bodily ailments? We may easily suppose the case (for such a one is on record) in which a distinguished consulting physician continues in practice for several years without prescribing a dose of medicine once in two years, or longer This man is certainly practising medicine And inasmuch as the "metaphysicians," "faith-healers" profess to cure disease and bodily ailments, and in some cases append the letters M D to their names, though signifying on their signs that they are "metaphysicians" or "faith-healers," are they not indictable under the Illinois Practice Act for practising medicine without licenses? At least one of these people has the letters M D appended to his name on his sign in Chicago From long custom the public understands that those letters mean Doctor of Medicine, though the person misappropriating them may say that they mean "Money Down," "Milk Diet," or "Medicine Disgusts"

The Secretary of the Illinois State Board of Health, in response to a question as to the legality of these people practising, says that he doubts if they could be prosecuted, but that he thinks that they could not collect fees should the person receiving the "treatment" decline to pay It seems, however, that the only ground upon which a court could refuse to enter judgment for the plaintiff in such a case would be that the plaintiff was practising medicine without a license, and therefore could not collect fees by law It is barely possible that a court might refuse to give judgment on account of "want of consideration," but this is only barely possible, and the plaintiff could almost certainly carry the case up on error But should the decision be as first suggested, the question at once arises If payment may be refused on account of illegal practice, why cannot the plaintiff be indicted for this illegal practice?

As evidence of the correctness of our definition of "practising medicine," we may cite the case of Bibber vs Simpson (59 Me , 181), in which suit was instituted for $51 for services rendered the defendants intestate, at his special request, by the plaintiff as a clairvoyant It appeared from the plaintiff's testimony that she professed to be a clairvoyant, that when asked to examine the patient she saw the disease and felt as the patient did, that sittings or séances were of different durations, from one-quarter to one-half of an hour each, that she did not pretend to understand anatomy or medicine, that she was requested by the intestate to visit him and render him professional services, and did so as by the account, that she helped him, but he died from taking cold, acquainted him with the prices, and he agreed to pay them, but never did so Appleton, C J , in deciding the case, said "The services rendered are medical in their character True, the plaintiff does not call herself a physician, but she visits her sick patients, examines their condition, determines the nature of the disease and prescribes the remedies deemed by her most appropriate Whether the plaintiff calls herself a medical clairvoyant, or a clairvoyant physician, or a clear-seeing physician, matters little, assuredly, such services as the plaintiff claims to have rendered, purport to be, and are to be deemed, medical "

Not only must the services rendered by these parties be deemed medical, but it must be held that the parties rendering these services publicly profess to be physicians, since a physician is one who claims to heal the sick And, says Attorney General McCartney, if it should be charged in an indictment or complaint that A B , on etc , etc , practised medicine without then and there possessing the qualifications prescribed in the certain act of the General Assembly of the State of Illinois, entitled "An Act to Regulate the Practice of Medicine in the State of Illinois," approved May 29, 1877, and without then and there having complied with the provisions of that act, and under this charge the prosecution should prove beyond a reasonable doubt that the defendent A B did, within eighteen months prior to the finding of the indictment, prescribe for the sick while publicly professing to be a physician, or that he did append to his name the letters "M D ," a conviction must necessarily follow, unless he should produce his certificate of the State Board of Health, his commission as surgeon in the United States Army or Navy, or prove himself to have so acted under one of the other conditions prescribed in the statute

RABIES —A farmer from Roumania, who had been bitten by a mad dog, was placed under Pasteur's treatment in Paris Notwithstanding, the disease developed in due time and proved fatal This makes the *eighth* death from hydrophobia after having been subject to a pretty fair test by inoculations by Pasteur himself The Roumanian was reported to have been bitten only thirteen days before coming under treatment by Pasteur

CHOLERA —Late advices represent cholera as prevailing with considerable activity in Venice, and two deaths from the same disease had taken place at Florence, Italy

SOCIETY PROCEEDINGS

AMERICAN LARYNGOLOGICAL ASSOCIATION

Eighth Annual Meeting, held in the Hall of the College of Physicians, of Philadelphia, May 27, 28 and 29, 1886

(Continued from page 667)

DR F I KNIGHT, of Boston, read a paper on

LARYNGEAL VERTIGO

A number of cases of what is called laryngeal vertigo have been reported by various authors The distinctive feature of these cases is that attacks of coughing are followed by giddiness and momentary loss of consciousness This latter symptom was present in all but two cases While it is probable that attacks of dizziness after coughing are not rare, yet but little attention has been paid to the subject The writer had been able to find fourteen published cases To these he adds two coming under his own observation The first case was that of a man aged 42 years, who had a chronic bronchitis of one year's duration He had had rheumatism when 15 years of age, and on one occasion had suffered with insom nia No morbid condition of the heart was detected The chest was filled with sonorous and sibilant râles Under the use of iodide of potassium there was gradual improvement After a day of worry and fatigue, he had a cough followed by loss of consciousness There was no evidence of spasm of the glottis and no convulsive movements He never had another attack of loss of consciousness

The second case was that of a lady 47 years of age, who had previously been the subject of attacks of dizziness, the result of indigestion She had suffered with winter cough for a number of years During one attack of coughing she lost consciousness During this time there was congestion of the face

The following points were obtained from a study of the reported cases All the cases with the exception of one have been in males The average at which the attack has occurred has been 47½ years The cough which induced the attack was slight in six cases, spasmodic in two, and severe in three Momentary loss of consciousness occurred in fourteen cases One case fell, but declared that he had not lost consciousness Dizziness is mentioned in eleven cases In four cases there seems to have been decided evidence of laryngeal spasm In one this was doubtful In four cases there was marked congestion of the head and face In two the patients were pale Convulsive movements of the limbs occurred in three cases In one the movements affected the face and head, and in another the face In these cases there was no biting of the tongue, no frothing of the mouth, and no involuntary micturition The speaker objected to the term laryngeal vertigo There probably is no real vertigo in these cases in the sense of the vertigo seen in aural vertigo There is simply giddiness or lightness of the head These cases can not be considered to be instances of petit mal

The cause of the attacks is disturbance of the cerebral circulation, perhaps due to the compression of the large blood vessels of the chest and perhaps the heart Even without this, the effect of rapid breathing is well known This causes marked cerebral disturbance

Dr D Bryson Delavan, of New York, read a paper on

BUCCAL TUBERCULOSIS

He had seen six cases of this affection In the reports of twenty-four cases of tuberculosis of the tongue, in all but one the subjects were males In twelve cases the lesion was anterior, in seven upon the side in one at the base of the tongue, and in four the situation was not stated The disease was primary in nine cases and secondary in seven cases In the remaining cases it was not stated whether the disease was primary or secondary The longest duration of a case of primary tuberculosis was two and one half years, the shortest ten weeks The age of the oldest person affected was 70 years, and of the youngest, not under 12

The first case coming under the speaker's observation was H , aged 35, a laborer His family history and previous history was good The man was remarkably robust Six weeks before coming under observation, he experienced pain at the base of the tongue This pain became excessive, and at the end of two weeks he was obliged to give up work On examination a fissured and ulcerated surface was found at the base of the tongue on the right side This lesion was indurated In the centre was a large ulcer with large flabby granulations On the right side, externally under the angle of the jaw was a hard tumor about the size of a chestnut There was slight fetor of the breath The diagnosis was uncertain, the pain was so severe as to prevent sleep An application of a 4 per cent solution of cocaine checked the pain for five hours The patient's condition became so serious that he was removed to the New York Hospital, where under the idea that the disease was epitheliomatous, the complete removal of the tongue was made The patient recovered rapidly from the operation and there was marked improvement in the general condition It has been impossible to find any evidence of disease of the lungs or other internal organs On microscopic examination all the parts present abundant tuberculous material A point of interest in this case, is that this is the first case on record in which such an operation has been followed by an apparent cure Of course sufficient time has not elapsed, to speak positively as to the ultimate result The operation was done in the latter part of December, 1885

In a second case of tubercle of the tongue, the patient, P O , age 27, gave no history of hereditary tuberculosis He began to run down two years ago, and developed chronic laryngitis When examined, he presented evidence of advanced tubercular disease The larynx was ulcerated There was also a lesion on the right tonsil and one on the left The pain on swallowing was severe Iodoform gave but little relief Temporary ease was given by cocaine An application of lactic acid was made to the right tonsil, and two days later it was much improved This was repeated and the improvement continued for two weeks, when the patient began to run down and died The bacillus tuberculosis was not found, but the man had evident pulmonary tuberculosis

The third case was that of a man, aged 43 Family history good No history of specific disease He was well until ten months ago, when his strength began to fail and cough came on Two months ago, the throat began to grow sore, and within the last two weeks this has increased Careful examination of the chest failed to reveal any evidence of disease Examination of the fauces showed ulceration extending out along the upper border of the uvula Later the signs of pulmonary involvement became evident Applications of lactic acid gave only temporary benefit In this case, the disease has extended along the gum

Three other cases of somewhat similar character were reported

Dr E L Shurley, of Detroit In these cases of so called primary tuberculosis mistakes of diagnosis are sometimes made He is not sure that the bacillus can be regarded as an absolute evidence that the disease is tubercle in one case, which he consid ered to be a case of tubercle of the larynx, and in which the bacillus tuberculosis was found, the patient recovered and is still living five or six years later

DR J O ROE, of Rochester I have had two well marked cases of primary tubercle of the pharynx The first case was that of a lady 35 years of age Six months before coming under observation she suffered great pain in the throat A well marked lesion was found above the border of the epiglottis and at the base of the tongue This improved under local treatment Subsequently the ulceration returned, the patient ran down in health and died The larynx was entirely free from ulceration The second case was a gentleman 40 years of age, who had tuberculosis ulceration of the larynx developed Under the persistent application of iodide of amyl continued for some time the patient recovered, and is still well, weighing 225 pounds

---

FRIDAY, MAY 28 SECOND DAY MORNING SESSION

At 10 o'clock the executive session was held, and the following business was transacted

The following were elected

OFFICERS FOR THE ENSUING YEAR

President—Dr E Fletcher Ingals, Chicago

1st Vice-President—Dr E Carroll Morgan, Washington

2d Vice-President—Dr J N Mackenzie, Baltimore

Secretary and Treasurer—Dr D Bryson, Delavan, New York

Additional Member of the Council—Dr F H Hooper, Boston

The following were elected

ACTIVE MEMBERS

Dr Benjamin F Westbrook, of Brooklyn, Dr Frank Donaldson, Jr, Baltimore, Dr Alexander W MacCoy, Philadelphia, and Dr J C Mulhall, St Louis

Prof Ramon de la Sota y Lastra, of Seville, Spain, was elected a *Corresponding Fellow*

A proposition in reference to the formation of a

CONGRESS OF AMERICAN PHYSICIANS AND SURGEONS

was received The proposition was approved, and the following committee, taken from the ex-Presidents of the Society, was appointed to confer with committees from other Societies Dr J Solis Cohen, Philadelphia, Dr G M Lefferts, New York, Dr F I Knight, Boston, Dr F H Bosworth, New York, and Dr E L Shurley, Detroit

It was decided to hold the next meeting in New York, the time to be determined by the Council

DR WILLIAM H DALY, of Pittsburgh, read a paper on

THE SIMPLEST AND MOST EFFICIENT TREATMENT OF DIPHTHERIA

His object was to describe the calomel treatment This is an old treatment It is mentioned in the writings of Rev Sydney Smith About 1779 Sydney Smith's daughter, when six months old, was taken sick with a violent attack of croup Dr Hamilton, of Edinburgh, was sent for, but not being able to come sent directions to "give the child two grains of calomel every hour, and to persevere He had never known this to fail" This was done and the child recovered

The credit of practicing and recommending this treatment in modern times belongs to Dr William C Ritter, of Pittsburg Of the different forms of mercury, calomel is the best The drug is to be given in doses of two to five grains every, one, two, or three hours It may be given dry and washed down with a little ice water, or it may be given in water This is to be continued until the stools become frequent and contain in them gelatinous masses of a bright green color, resembling chopped spinach Then the interval is to be lengthened and the drug continued so as to keep up this condition of catharsis, the patient having two or three stools each day It is better to lengthen the interval than to diminish the dose In this way there is less liability to induce ptyalism Very little depression follows these large and frequently repeated doses Ptyalism does not often occur Under this treatment the membrane exfoliates and re-forms, if at all, with less readiness The fever diminishes The diet is to be of a light, nutritious character

DR E L SHURLEY, of Detroit, agreed that the internal administration of calomel is one of the most efficient remedies for croupous inflammation, but in regard to its efficiency in the treatment of diphtheria, he could not agree The difference between croupous inflammation and diphtheria is considerable He knew of no cases of diphtheria relieved by the calomel treatment

DR F DONALDSON, of Baltimore, wished that Dr Daly had given us some statistics and reported some cases He had seen the calomel treatment frequently tried, but without success He saw Trousseau treat cases of diphtheria in that way, but he finally abandoned it

DR BEVERLY ROBINSON, of New York, said there was scarcely a remedy which had not, at some time, been recommended as a specific for diphtheria Calomel has been thoroughly used, and finally given up because it did not accomplish what was proposed He was convinced that epidemics of diphtheria, as of other infectious diseases, differ very much in virulency, and a remedy which is successful in one epidemic will entirely fail in another He believed that in treatment it is safer to follow what has been considered by the accurate men of our profession, in large numbers, the most reliable treatment for a disease of this character There is a general consensus of opinion that the proper line of treatment is disinfection of the throat and air passages, with the use of smaller or larger doses of the tincture of iron, combined or not with chlorate of potassium

DR F H BOSWORTH, of New York, said diphtheria is a blood poison, which often kills by its toxic effect, but in a greater majority of cases it kills by leading to the development of croup The affection of the larynx is not diphtheria, but a sequent disease While he thought that mercury had no effect upon diphtheria, he believed that it had a specific effect in arresting the disease in the larynx called croup He believes that mercury is the remedy to be administered in croup

Dr. Daly was not surprised that this method of treatment had not been received with favor He did not receive it favorably when it was presented to him He did not recommend calomel as a specific He simply said that he had a greater proportion of successes under this plan of treatment than under any other which he had tried

Dr E Carroll Morgan, of Washington, read a paper on

THE QUESTION OF HÆMORRHAGE AFTER UVULOTOMY, WITH THE DESCRIPTION OF AN INSTRUMENT FOR ITS ARREST

The speaker described the following case A man aged 28 years, whose uvulu had been excised five days previously by another operator, came to him with the statement that the bleeding came on four hours after the operation, and had continued at intervals since then, a large quantity of blood having been lost Various means had been tried to stop the bleeding, without success The parts were covered with a coagulum of the persulphate of iron This was removed and the parts cleansed The bleeding points were then seen The uvulu evidently had been greatly hypertrophied The scissors had been used in the operation There was no evidence of the hæmorrhagic diathesis in this patient, or in any members of the family The parts being cleansed, the stump was seized with dressing forceps and the hæmorrhage was controlled The galvano cautery was applied and the bleeding stopped In nine hours it recurred The cautery was again used and the stump dusted with the persulphate of iron The following morning a copious hæmorrhage took place, not less than a drachm a minute, by actual measurement, being lost A careful examination was then made to detect any other source of hæmorrhage, but none could be found Chromic acid was then used and the hæmorrhage stopped At three o'clock the same day copious bleeding recommenced Galvano-cautery was again employed There was not room for the application of a ligature Torsion was tried without success A small clamp used in retaining shirt sleeves in position was then taken, the spring weakened, and the teeth filed down, was then applied A string was attached to this and brought out of the mouth This checked the bleeding and was allowed to remain for several hours It was then removed and the bleeding did not recur A search of the literature of the subject failed to show any instance in which such a procedure had been before adopted In this case he thought that this device had saved the patient's life

A careful study of the subject has enabled him to find seventeen other cases in which the hæmorrhage after this operation had been profuse Death has never resulted directly from the hæmorrhage after uvulotomy Where the bleeding is persistent it is always arterial in character

The speaker, in conclusion, said that a fatal hæmorrhage had never followed uvulotomy A persistent alarming hæmorrhage is only encountered in the rarest instances A moderate bleeding, stopping spontaneously or by the use of the mildest applications, occasionally happens A loss of a few drops of blood at the time of operating, followed by a slight oozing, is a common occurrence

The most reliable surgical measures for controlling uvular hæmorrhage are, ligature, compression by a clamp or forceps, and the use of the actual cautery The most reliable styptics are, in the order named, solid nitrate of silver, persulphate of iron, gallic acid, tannic acid, alum, the local use of ice, and vinegar The most reliable systemic remedies are opium, acetate of lead, sulphuric acid, and ergot The speaker recommended that in operating, the object should be to restore the uvula as nearly as possible to its normal size, and that the entire uvulu should not be removed

Afternoon Session

Dr Thomas R French, of Brooklyn, read a paper on

THE LARYNGEAL IMAGE AS SEEN IN PHOTOGRAPHS TAKEN DURING THE PRODUCTION OF TONES IN THE SINGING VOICE

The speaker had made numerous investigations in this subject, and his observations failed to confirm the statements of most authorities in regard to the position of the vocal cords during the production of different notes in the singing voice Different individuals evidently use different mechanisms in the production of different tones The general result of his investigations seemed to indicate that in the production of low notes the vocal cords are separated to a greater extent posteriorly than anteriorly In the production of the middle tones, the vocal cords are parallel, and in the production of high notes the opening is widest in front The paper was illustrated by numerous photographs thrown upon the screen

The following papers were then read by title *Clinical Notes on Prolapse of the Laryngeal Ventricles,* by Dr Geo W Major, of Montreal *Three Cases of Thyrotomy, Recovery in Each Case, with Good Voice,* by Dr Clinton Wagner, of New York *Alarming Hæmorrhage after Tonsillar Excision, Arrested by Torsion of the Artery,* by the same author

Dr Wm C Jarvis, of New York, described

A NOVEL PROCEDURE FOR THE REMOVAL OF SUBGLOTTIS LARYNGEAL GROWTHS

The following case was described

J C, aged 35 years, consulted me on March 22, 1882, for the relief of a difficulty of speech and of breathing The trouble with the voice was noticed two years before, the difficulty in speech appeared one year before coming under observation The laryngoscope showed a mass of papillomatous tissue occupying the cavity of the larynx The vocal cords and ventricular bands were not involved The attempt was made to seize the growth during phonation with the Mackenzie forceps, only a few pieces were removed The écraseur was then tried, but it was found impossible to use this instrument on account of the wire being seized by the spasmodic contraction of the vocal bands and displaced. Chromic acid applications were then tried, but although the growth was touched, it was found impossible to limit the application to the diseased structures. The patient then disappeared and did not return for a year. His condition was then much worse, and the difficulty of breathing greatly increased.

It was then determined to try the following plan, and if this failed, to remove the growth through an opening in the wind-pipe. Forceps similar to the Mackenzie instrument, but heavier, was secured. Through the tips of the blades holes were drilled, and through these was passed a piece of No. 00 piano wire, which was conducted through a second opening at the angle of the blades and out to the handles, where it terminated in a loop into which the extremity of the index finger could be placed. When the blades were separated this wire formed a cross-bar uniting their extremities. When the blades were closed the loop of wire could be drawn up by the finger. The operation was performed without an anæsthetic. The tongue was depressed and with the aid of the mirror the forceps was introduced into the cavity of the larynx. The mirror was then removed and the forceps carried down to the glottis, through which the tip of the instrument was forced with considerable trouble, on account of the spasm. The instrument was carried into the trachea sufficiently far to be sure that it was below the attachment of the growth. The blades were then separated, and pressing against the anterior wall of the larynx, the instrument was gradually raised until the wire was caught. The blades were then closed and clamped, the loop of wire drawn in and the forceps removed, bringing with it a growth. The laryngoscope showed a second growth, which was removed in the same way. Breathing was at once rendered easy and the speech became natural. The patient said that the presence of the forceps caused no pain, although uncomfortable. This is the only case on record of the removal of a sub-glottis tumor without anæsthetization, and without an opening into the larynx.

Dr. T. Amory DeBlois, of Boston, read a paper on

CASES OF LARYNGEAL ŒDEMA.

The author gave brief details of fourteen cases of laryngeal œdema coming under his observation. All of these cases recovered, six under the use of astringents, and eight after scarification.

Dr. Frank Donaldson suggested that in these cases intubation of the larynx, after the O'Dwyer method, might be applicable.

Dr. E. Carroll Morgan said his experience with this condition had been limited, and the cases had been mild. He usually employed active purgation, with vesiculation over the larynx and various local measures.

Dr. W. C. Jarvis some time ago used, in a case of marked œdema, the fluid extract of jaborandi. In forty-eight hours the œdema had greatly diminished. He had since seen reported several cases in which pilocarpin was used with advantage. He had never seen good results from scarification.

A paper by Dr. Charles H. Knight, of New York, describing *A Case of Perichondritis of the Larynx*, was read by title.

Dr. Edgar Holden, of Newark, reported

A CASE OF GUMMATOUS DISEASE OF THE LARYNX, WITH SPONTANEOUS RE-OPENING OF THE LARYNX AFTER THYROID LARYNGOTOMY.

L. D., aged 35, presented himself, May 20, 1885, with dyspnœa and aphonia. Examination showed a cicatrix on the epiglottis, and the left side of the larynx presented a rounded mass of dull appearance. He denied syphilitic infection. After a careful consideration of the case, the probabilities were thought to favor syphilis, and he was given iodide of potassium in large doses. There was improvement for a short time, but he soon became intolerant to the drug. Thyroid laryngotomy was considered necessary and was performed. The tumor was removed with the écraseur; no ulceration was visible. Tracheotomy was then performed, and the upper incision closed with sutures. The patient did well and the tube was removed on the tenth day. The external wound healed. He insisted on returning to his home, where the surroundings were very unfavorable and his health deteriorated. On the fortieth day after the healing of the wound, the laryngeal incision was torn open by a severe cough. He refused to return to the hospital. Examination of the larynx showed no disease. Under the surroundings it was impossible to get the wound to heal. His health continued to run down, and six months and fourteen days after the operation the patient died of exhaustion. The patient had lived five months with an opening in the larynx.

Dr. U. G. Hitchcock, of New York, read a paper on

GUMMATOUS INFILTRATION OF THE BASE OF THE TONGUE,

giving the details of four cases coming under his observation. In none of these cases was the fibrous septum the exclusive seat of the disease. In three cases, the deposit did not approach this structure. In these cases the degree of dysphagia was in direct proportion to the proximity of the deposit to the base of the tongue.

Saturday, May 29, Third Day—Morning Session.

A paper on *A Case of Hysterical Sneezing, Apparently Cured by Applications to the Nasal Passages of the Continuous Battery Current*, by **Dr. S. Solis Cohen**, of Philadelphia, was read by title.

Dr. John N. Mackenzie, of Baltimore, read

A CONTRIBUTION TO THE PATHOLOGY AND TREATMENT OF THE RESPIRATORY VASO-MOTOR NEUROSES.

The naso-bronchial tract is frequently the seat of periodical vascular disturbance in which explosions of nerve force play a conspicuous part. These probably depend upon some form of sympathetic or vaso-motor irritation. In the production of such conditions two elements enter: a depraved state of the nerve centres and an abnormal excitability of certain portions of the naso bronchial tract In regard to the hyperæsthetic condition of the nasal mucous membrane, the hyperæsthesia characteristic of the paroxysm is like the vaso-motor phenomena which accompany it, purely secondary, and occurs as a result of central irritation or paresis This may pass away with the subsidence of the other symptoms or be more or less constant But in either case, there are certain areas in which the hyperæsthesia is more pronounced The lower, posterior parts are the portions of the tracts usually affected In hay fever we are dealing with a neurosis In this connection, he called attention to a neurosis of the aural cavity which was closely allied to vaso-motor coryza and also to a similar condition of the conjunctiva These cases are a further evidence of the sympathetic nature of these affections With reference to asthma in connection with nasal disease it was stated that the ancients had frequently noted the expulsion of mucus from the nostril accompanying or following an attack of asthma The older writers were evidently familiar with hay fever, but they confounded it with the bronchial asthma of the present day Asthma is looked upon as a disease *per se*, but, like many other disturbances of respiration, it has no particular lesion and is common to many pathological states It, like cough, is most commonly symptomatic of some dis order of the respiratory tract An interesting feature in a certain proportion of cases is the association of urticaria with coryza This is a familiar observation The speaker then considered the relations between the skin and the respiratory tract He regarded the skin as having a function similar to that of the lungs, on the principles which he explained he based the treatment of hay fever, or periodical vaso motor neurosis of the respiratory tract From sixty to eighty cases had been treated after this plan In the greater number of cases the nasal passages were the seat of the vascular disturbance Next in frequency came the pharynx Occasionally it was localized in the laryngeal cavity In whatever portion the vaso motor neurosis is situated, the general principles are the same The treatment of one of these affections is essentially the treatment of the others Hay fever and asthma may be classed as symptoms owing their origin to the same cause

In the treatment of hay fever the chief indications are to remove any existing local respiratory disease, to so alter the nutrition of the nerve centres that they may not respond so easily to irritation, and to care fully search for pathological conditions and adopt ap propriate treatment for their removal when found

These chronic neuroses require chronic treatment The peculiarity of the sympathetic is with the patient all the time, by night and by day, and at any moment may give evidence of its presence by a paroxysm Any treatment which is practised simply during the attack or immediately before is simply palliative In reference to the use of cocaine, he had found that it increased the irritability of these structures, and its application to the erectile tissue may ultimately weaken the cell walls He, however, did not ques tion the excellent virtues of this remedy in certain acute affections In hay fever he had failed to find improvement after its use For a short time amelioration was produced, but in the course of an hour the symptoms recurred His custom is to treat hay fever as any other chronic disease of the nervous system He insisted upon a prolonged tonic course of treatment during the intervals This may at first fail, but if persisted in, the time will come when, if there is no incurable lesion, the paroxysms will diminish in severity and frequency The great mistake is made in the suspension of the treatment upon the termination of the attack Among the remedies for the constitutional management of this class of cases he recommended phosphide of zinc, quinine and nux vomica These may be given in combination in the following proportions

℞ Zinci phosphide gr 1 16
Quiniæ sulphat gr 2
Ext nucis vomicæ gr ¼
M Et ft pil No 1
Sig To be taken before meals

After meals he directs that from 3 to 5 drops of liquor arsenici et hydrargeri iodidi be taken in a wine glassful of water A similar line of treatment had been employed for several years by the speaker in simple inflammatory conditions of the nose and throat with good results He had also employed bromide of potassium with advantage A constant current of from ten to fifteen cells, with one pole over the nape of the neck and the other over the region of the superior cervical ganglia or in the nasal passage has in a few cases been beneficial In one case improvement followed the obliteration of vessels on the posterior wall of the pharynx

In regard to topical applications to the existing nasal conditions, these accomplish one result only They close the door to irritation of the nerve centres In many cases this is of itself sufficient There are other cases in which such a course will fail In these neuroses, we cannot expect to thoroughly eradicate the disease until the sympathetic nerve irritation is overcome

DR WILLIAM H DALY The iodide of sodium has given him better results than any other single remedy He gives it in small doses long continued The upper air passages should be carefully examined, and upon the slightest suspicion of local disease, the condition should be remedied If this is done, he believes that the disappointments will be few The constitutional treatment should, he thinks, be secondary to the local treatment

DR E CARROLL MORGAN The galvano cautery has been highly recommended as a successful remedy for hay fever, but his experience with it has not been so satisfactory as that of some other operators In considering these cases of hay fever, he has been struck with the apparent immunity from this affection experienced by those suffering with anosmia He has never seen essential anosmia in a subject of hay fever He would ask the experience of the Fellows in regard to the efficacy of the galvano cautery treatment as a preventative or a cure for hay fever

DR C E SAJOUS, of Philadelphia In the early part of his experience with the galvano cautery, he had a number of favorable cases Last year he met with a number of unsatisfactory cases What it depended on he does not know, but the results were not by any means as good as those of the preceding year It certainly was not from want of attention on his part Although all the cases were benefited, he thinks he did not obtain absolute relief in more than 45 per cent Some of the cases treated two years ago, and which escaped the attack the following year, had a recurrence last year This is a matter of great importance, because in his work, he advanced the opinion that these cases were absolutely cured Some of the cases have entirely escaped One case treated in 1881 with glacial acetic acid has had no recurrence

Dr Carl Seiler, of Philadelphia The failures of the treatment of hay fever may, he thinks, be explained by the supposition thrown out in the paper read The Schneiderian membrane is not the only source of irritation of the vaso motor nerves The source of irritation may be situated in the pharynx or in the larynx If the case does not yield to treatment of the nasal membrane we should look further Two years ago a case of hay fever presented itself to him Glacial acetic acid was applied, and the following summer he was free from hay fever, but suffered with asthma Examination showed a large posterior hypertrophy, this was removed, and since then, he has had neither hay fever or asthma

Dr Samuel Johnston, of Baltimore, read a paper entitled

A CASE OF NASO-PHARYNGEAL GROWTH

A child was brought to him on account of difficulty in breathing through the nostril Examination showed that there was a tumor filling up the posterior part of the right nostril After a short preliminary treatment, the attempt was made to remove the growth with the écraseur A spray of a 4 per cent solution of cocaine was employed A cord was first passed through the nostril and brought out of the mouth, so that if necessary, the nostril could be plugged without delay The wire of the écraseur was applied without difficulty When the growth had been cut through about two thirds, the shaft of the instrument broke, leaving the wire and about three fourths of an inch of the instrument attached to the growth An attempt was made to apply a second écraseur, but this failed After trying to remove the portion of instrument broken off, it was decided to wait a short time and allow the growth to slough off Four days later the attempt to apply an écraseur was again made and succeeded without difficulty The tumor measured one and one-half inches in diameter and was fibroid in character

Dr C C Rice, of New York, read a paper entitled

WHAT CASES OF NASAL CATARRH REQUIRE SURGICAL TREATMENT?

Almost every nasal chamber will exhibit irregularities and abnormalities of some kind The introduction of more improved methods of determining the locality of inflammation has led to a more frequent resort to surgical measures With the galvano cautery almost any effect, from a slight stimulation to destruction of tissue, can be obtained Those who condemn this instrument should state what use of it they object to Not every case of anterior hypertrophy should be operated upon The erectile tissue in this situation serves a valuable physiological function in swelling up and excluding irritating particles from the lungs In determining whether or not an operation is required, the sensations of the patient should be taken into consideration, with the results of the examination If after the use of a four per cent solution of cocaine, sufficient hypertrophy to interfere with breathing is still apparent, it should be removed

Dr F H Bosworth said the speaker had referred to the erectile tissue of the nose as possessing a physiological function He considered that this tissue is not a true erectile tissue It assumes the erect position only as a morbid condition It is simply an enlarged conglomerate mass of blood vessels There is no physiological function observed by its swelling up The speaker also states that all persons will present abnormalities of the nose It is a mistake to suppose that we have morbid conditions in every nose The healthy nasal cavities present a typical appearance

Dr J N Mackenzie said the microscope shows that the erectile tissue of the nose corresponds with the erectile tissue in other portions of the body He believed that these bodies serve the physiological purpose of excluding irritating bodies from the lower respiratory tract Experiments with horses driven through a cloud of dust have shown that while the anterior portion of the nose was filled with dust none passed into the larynx

The President thought the question of the erectile tissue of the nose should be treated on a broader basis In man the nasal chambers are exceedingly degenerate There is no animal in which the nose is so small in comparison with the rest of the face, as in man It is well known that structures which are passing through a process of degeneration are exceedingly variable So it is with the human nasal chambers Remembering this fact, we come to another of great interest, that all animals with short faces, as the rabbit and cat, have on the nasal septum, erectile bodies He had always held that the object of these bodies was obstructive, and that by swelling up they protected the portions behind If that is the case, he could not see why we cannot claim that erectile tissue exists in man It is his opinion that erectile tissue does exist, and is protective and obstructive

The following papers were read by title *Inflammation of the Antrum*, by Dr Beverly Robinson, of New York *Additional Notes on a Case of Erysipelas of the Larynx*, by Dr Wm Porter, of St Louis

A vote of thanks was then tendered the Philadelphia College of Physicians, the Union League Club, the University Club, and the managers of the Pennsylvania Hospital, for courtesies received, and the Association then adjourned

DOMESTIC CORRESPONDENCE

LETTER FROM NEW YORK

(FROM OUR OWN CORRESPONDENT)

The Future Influence of Surgery and Surgical Resources upon Obstetrics—Amendment to the Constitution of the Academy—A Pasteur Institute

At the meeting of the Academy of Medicine held on June 3, Dr C C Lee, one of the surgeons to the Woman's Hospital, read a paper on "The Future Influence of Surgery and Surgical Resources upon Obstetrics" It was, to be sure, almost exclusively devoted to the past, but the idea was, that since surgery had already had such a marked effect upon midwifery, it was reasonable to suppose that still greater triumphs were in store for it in this department There was nothing, he said at the outset, more impressive to those interested in the subject of obstetrical procedure than the rapid inroads made within the last four years by surgery into a domain which had been hitherto regarded as one purely medical

He first took a glance at the history of the art of midwifery from the earliest times, giving the ancient Egyptians full credit for the very considerable progress which they made in it, and then, gradually coming down to more recent periods, he took up the subject of the Cæsarean section and gave an account of its history, its dangers, and the method of its performance, after which he spoke of the four modifications of the operation suggested respectively by Francke, of Cologne, Sanger, of Leipsic, and Kehrer and Cohnstein, of Heidelberg Kehrer's method is described as consisting of a transverse incision through the anterior convex surface of the uterus at the line of the *os internum*, of deep sutures to secure immediate contact of the peritoneal borders, and of strict antiseptic precautions during the operation, combined with subsequent drainage of the abdominal cavity In order to cover the line of incision with peritoneum he directs that the latter be separated from the underlying muscle for nearly a half inch from the borders of the wound Dr Lee gave a detailed description of this procedure, as well as of Sanger's "subperitoneal muscular resection," and its modification by Leopold, and of the method proposed by Cohnstein, to turn the uterus completely out of the abdomen, and open it from behind, which, so far as he knows, has never as yet been attempted in actual practice

In order to show that the great danger in connection with the Cæsarean section arises from the delay commonly made in resorting to the operation, he quoted the opinion of Dr Robert Harris, of Philadelphia, whom he pronounced not only the highest authority on Cæsarean section, but the greatest medical statistician that this country has ever produced He then went on to speak of the substitutes which had been devised to take the place of this operation, first describing Porro's operation, which involves the removal, after the performance of the Cæsarean section, of both uterus and ovaries, and its modification by Muller, who recommends that the uterus, after the enlargement of the abdominal wound, shall be tilted laterally, and withdrawn outside the abdomen previous to section

Dr Lee spoke in high terms of the other substitute for Cæsarean section, laparo elytrotomy, as suggested and successfully practised by Dr T Gaillard Thomas Although this procedure was proposed as long ago as 1806 by Jorg, who, however, contemplated cutting through the peritoneum, and again in 1820, by Ritgen, and in 1822 by Physick, of Philadelphia, Dr Thomas was unaware of these facts at the time he worked out the problem for himself by a number of operations on the cadaver Dr Lee thought that he was fairly entitled to the credit of the operation, and that if he had accomplished nothing else, this achievement alone would serve to hand down his name to posterity as one of the great masters of obstetric surgery By this method the dangers of opening into the perineum and wounding the uterus are avoided by an incision of the abdominal parietes along the upper edge of Poupart's ligament, lifting the peritoneum, dissecting down to the vagina, dividing the latter transversely, and then, having reached the cervix, extracting the child through the passage thus artificially created Although the number of cases in which laparo elytrotomy had been performed was as yet comparatively small, the proportion of successes thus far had been much greater than had been met with either in Cæsarean section or the Porro or Porro–Muller operation During his subject, Dr Lee quoted a number of statistics, which were almost entirely taken from Dr Harris's recent article in the International Encyclopædia of Surgery

He next took up the matter of extra-uterine pregnancy, and showed what excellent results had been accomplished by the use of electricity in the earlier months, as first successfully employed by Dr J G Allen, of Philadelphia Having spoken also of the results obtained by elytrotomy and laparotomy in the later months of ectopic gestation, he went on to treat of lacerations of the cervix uteri, and condemned the primary operation in such cases Personally, he said, he had never been successful in securing union by this procedure, and he knew of but one surgeon who claimed to get good results from it In a large number of cases which are left to nature no subsequent operation was required

With regard to lacerations of the perineum, however, the case was very different Here the advantages of immediate closure were so immense that he regarded it as a matter of great importance, and he said that he would now as soon think of leaving a parturient with an undelivered child in the uterus as to neglect to sew up a torn perineum The omission to do this was the source of much suffering and misery which might otherwise have been avoided Notwithstanding the fact that operative surgery had already accomplished so much in the field of obstetrics, he felt confident that, judging from the triumphs of the last few years, the results noted would be still more satisfactory in the future

Dr Wm M Polk remarked that for a considerable period after he commenced the practice of medicine, he ranked himself as strictly a physician In the course of time he became an obstetrician, but he entered upon his work in this department with the conviction that it was simply a branch of the physician's art This feeling was to a great extent due to the training which he had received, and especially to the teachings of Professor Fordyce Barker After a short time, however, he began to appreciate the fact that there were certain points in obstetric practice involving surgical methods, which if, at the present stage of scientific progress in the profession, a man were to neglect, he would soon be driven to the wall It was only recently, indeed, that obstetricians had become alive to the fact that the domain of their art was in reality one of vast scope In the English hospitals, more than in this country, they have had to fight their way surgically against the mere physicians, and also to contend against the active opposition of those recognized as general surgeons But the same had been true to a considerable extent here also, and he was happy to say that the obstetrician, notwithstanding the indifference manifested on the one hand, and the active opposition on the other, had now won for himself an enviable position By way of illustration he need only point to the matter of abdominal section

' At one time vesico-vaginal fistula was almost as much a reproach to the profession as cancer, but at present large numbers of women were perfectly relieved who formerly would have been left to drag out lives of misery and suffering But the pendulum, once started, was apt to swing a little too far, and it was perhaps true that to day the obstetric surgeon was not infrequently a little too free with the use of his knife As to lacerations of the cervix resulting from parturition, he had seen many serious cases (the rent sometimes extending to the vaginal roof), recover perfectly under ordinary treatment, without resorting to operative measures, and his views on this point were quite in accord with those expressed by Dr Lee Surgeons complained that the abdominal cavity was opened too often at the present day It might be, but that was simply a side issue Before the obstetricians of to day, Dr Polk said in conclusion, lay the grandest problem that could possibly engage their attention, viz that in connection with the Cæsarean section He did not doubt that within the next ten years it would be possible to entirely eliminate from practice that most repulsive of all obstetrical procedures, the destruction of the life of the fœtus by craniotomy When this had been accomplished there would have been achieved the greatest triumph ever won in surgery, and the honor of it would belong to the obstetrician

Dr Fordyce Barker, in making some remarks on the primary operation in laceration of the perineum, said that he was not inclined to accept any new proposition until time and experience had determined its real merits, and for a long time he had held his opinion on this subject in abeyance Some years ago, at a meeting of the American Gynecological Society, a distinguished obstetrical authority had made the statement that any physician who did not close by primary operation a rupture of the perineum occurring in his practice was guilty of a neglect of duty He did not express any positive opinion in regard to the matter at that time, but he hesitated to accept this dictum as correct, and at the present time he was still less inclined to acquiesce in its sentiment He then made the announcement that in no case that he had ever attended in his private practice had a secondary operation been performed, and this was simply for the reason that it had never been required He did not mean to say that he had never had any perineal lacerations, but only that none of them are of such a character as to demand a secondary operation The uterus retained its position perfectly in every instance, and no other bad result occurred from the rupture He could say, furthermore, that up to the past winter, in no private case of his had a primary operation ever been performed

Dr Barker then referred to a peculiar epidemic which had occurred in this city during the six months ending May 1 There were no unfavorable symptoms until about the sixth day after labor, when an explosion would suddenly occur in the system, the temperature rapidly running up to 104, 105 or 106° In consultation he had seen forty such cases, but only one case had occurred in his own practice As a rule, the symptoms all disappeared within three days, and out of the forty he was called to see only twenty more than once There was, however, one fatal case It was a significant fact, he thought, that in five out of the forty cases the primary operation for lacerated perineum had been performed, but in only one of them did union take place In the case occurring in his own practice there was a bad laceration, as the labor was a very difficult one, but the result of the primary operation was unsuccessful

In two cases that he knew of, in which immediate closure of a ruptured perineum was effected, there was profuse uterine hæmorrhage, as a result of shock After referring to other cases, he said that his mature opinion was, that while there were, no doubt, cases in which the condition of the patient was so favorable that primary union was likely to result from an immediate operation, yet as a rule it was safer to avoid the operation, and trust to absolute cleanliness and watchful care of the patient If there was any tendency to septic trouble, he believed that the sewing up of the perineum would be likely to be attended with unpleasant consequences on account of the interference which was thus caused to free drainage

Dr Barker then went on to speak of the marked influence which the gynecologist has had upon the surgery of the present time, and in this connection referred to the last paper which Dr Marion Sims had read before the Academy, in advocacy of laparotomy in traumatic lesions of the abdomen, when the late Dr James R Wood, in a forcible address, had argued against this procedure, on the ground that while the gynecologist could carefully prepare his patient for the operation, the general surgeon would be called upon to operate suddenly, and under the most disadvantageous circumstances

Dr Malcolm McLean said that he felt compelled to advocate the desirability of the primary operation in lacerations of the perineum He had found that in those cases in which he sewed up the laceration with soft silk sutures, the result was more satisfactory than in those which were left to nature He did not believe in using silver wire sutures, as they were apt to displace the parts, but silk sutures, deeply and carefully placed, were generally efficient and satisfactory, while they had the advantage, at all events, of not doing any mischief, even if they did not accomplish the desired result However, this procedure served a good purpose by its moral effect, in backing up the accoucheur in case union did not take place, for in these days when so much was expected of one from a surgical point of view, a reflection was apt to be cast upon the medical attendant if there resulted a permanent laceration in which there had been no attempt made to secure union by operative measures In the main, however, he had found this simple operation of decided practical advantage

Dr Polk then stated that he entirely acquiesced in the opinion expressed by Dr McLean He would admit, however, that there were exceptions, in which the conditions described by Dr Barker contraindicated the primary operation There were many cases in which the accoucheur had had a bad operation, or labor had been unduly prolonged, where the existing condition of shock would be likely to be followed by hæmorrhage, and here we are justified in declining to operate We should always be sure that the patient had not already been subjected to the risk of shock before we made any attempt to repair the laceration It was now some time since he had abandoned the use of wire sutures in either primary or the secondary operation It was natural that the latter should have been preferred to all others before the days of antiseptic surgery, but silk properly prepared, and soaked in a bichloride solution, was altogether better than the metallic suture, which was always a cause of great pain and annoyance to the patient

In closing the discussion, Dr Lee said that he differed from Dr Barker in regard to the question of primary operation in perineal lacerations It might be that he had not been able to place his patients under the same favorable conditions for spontaneous recovery which the latter had, but, at all events, he had not been fortunate enough to obtain the same satisfactory results when such cases were left to nature He then referred to the practice observed in the lying in Department of the New York Foundling Asylum, in which the patients were nearly all primaparæ In this institution it was the uniform rule in every case, whether the patient was attended by the house surgeon or one of the visiting physicians, that immediately after labor the condition of the perineum should be carefully ascertained, and if it was found to be decidedly torn, to close the laceration at once Of course he did not wish to be understood as advocating an operation when there was merely an abrasion, or a tearing of the fourchette, such as was almost universally the case with primaparæ He did not believe, either, in operating when there was profound shock present from loss of blood, or other cause, but he had very rarely met with such a condition in his practice

The plan which he adopted was simply to continue the chloroform under the moderate use of which the child had been born, and to make an examination of the perineum, when, if a decided rupture was found, the chloroform was still kept up, and the laceration repaired by means of silk sutures Like Dr Polk, he had not in some time employed silver wire sutures in either primary or secondary operations If the posterior wall of the vagina was involved in laceration, he usually put in two or three catgut sutures at this point The whole operation was a very simple one, but he always performed it under chloroform, and he had never seen shock caused by it In his practice at the Woman's Hospital he had seen so many bad results, which might have been avoided, which were the direct consequence of ruptures of the perineum which were allowed to go without operative interference at the time of their occurrence, that he was firmly convinced as to the great utility of the primary operation

At this meeting the Academy passed the amendment to its constitution which has before been referred to, which gives it once more the undisputable right to discipline its Fellows "for cause "

A meeting was recently held at the house of Dr Alexander B Mott, for the purpose of organizing a Pasteur institute in this city, for the treatment of persons bitten by rabid dogs It was estimated that about $5000 would be required for the first year's expenses, and it was accordingly decided to issue an appeal to the public for subscriptions, as it is proposed to have the inoculations entirely free Dr Valentine Mott has recently returned to this city from Paris with a rabbit inoculated by Pasteur, and it is stated that this is the first time that the latter has permitted his virus to go out of his own hands, which certainly is very complimentary to Dr Mott It would seem that this movement is a little premature at the present time, but if the success of Pasteur's process is finally demonstrated, of course it is only a question of time when such institutes will be established in many large cities in various parts of the world The officers of the proposed institute are as follows President, Dr Alexander B Mott, Vice-Presidents, Drs Alexander F Liantard and Louis Deplasse, Recording Secretary, Dr Charles Villa, Corresponding Secretary, Dr Valentine Mott

ILLINOIS COLLEGE OF PHARMACY

To the Editor of the Journal

Dear Sir —Being a strong advocate of advanced medical education, and hence by necessity of properly educated pharmacists, it is with a feeling of regret that in the May 22 number of The Journal, I notice, in an announcement of a new pharmaceutical college, what is, in its essence, an attack on the best interests of pharmacy, and hence of medicine, in Illinois It was said by Prof Oldberg, (*Pharmacist*, June, 1885) that, "it requires a very considerable outlay of money and large classes to maintain an efficient college of pharmacy, and the multiplication of schools without visible means of support is to be condemned There are already more colleges and schools of pharmacy, than there is any demand for, and each new addition is a positive injury to the cause of sound education "

Judged by this standard the establishment of a new college of pharmacy, on the grounds alleged in the editorial, was indefensible The only grounds on which the establishment of a new college of pharmacy could be justified from an ethical standpoint, would be that the old college was lowering its standard of graduation and education, whereas the opposite was the case, and was demonstrably the cause of the secession which led to the establishment of the new college None of the gentlemen mentioned as the prospective faculty can be considered pharmacists In the establishment of a college of pharmacy the scientific and not the commercial aspect deserves the first consideration In creating a new college of pharmacy Prof Oldberg and his colleagues have (*to use his own words*), therefore, positively injured the cause of sound pharmaceutical education

Very truly,
FRED M SCHMIDT, Ph G
Secretary Chicago College of Pharmacy

DANGERS OF KISSING

TO THE EDITOR OF THE JOURNAL

Dear Sir —The paper recently published in your journal on "The Dangers of Kissing" has apparently attracted the attention of the medical profession Private communications and clippings have encouraged me in an attempt to pursue the study further Consequently, I hereby request the reports of cases of disease having been communicated by kissing, for use in another paper Very truly, etc ,

BOOK REVIEWS

DIAGNOSIS AND SURGICAL TREATMENT OF ABDOMINAL TUMORS By SIR SPENCER WELLS, BART , etc Sm 8vo , pp 216 Illustrated Philadelphia P Blakiston, Son & Co 1885 Chicago W T Keener

Though this volume might be called a fourth edition of a book published in 1865, it is necessarily in very many respects a new work In scarcely any department of medicine have two decades made more marked changes than in the treatment of abdominal tumors Twenty-five years ago when a physician undertook the treatment of an abdominal tumor he began a journey in the dark Ovariotomy sometimes succeeded, in which case the surgeon was considered lucky, but it as often failed, and was very generally discredited

The first edition of this book might have been called a plea for ovariotomy, to day it is no longer necessary to enter any plea at all for the operation After the publication of the second, in 1872, Mr Spencer Wells thought that with a record of 500 cases he might with propriety go into the diagnosis of ovarian disease and the details of ovariotomy The third book, in 1882, included uterine pathology and surgery, which had been grafted upon that of the ovary The present book goes still farther, and presents the most advanced knowledge of one of the greatest of specialists It is divided into two parts, the first devoted to "Ovarian and Allied Tumors," and the second to "Uterine and other Abdominal Tumors " Every one knows who Sir Spencer Wells is, and what he has done The volume under consideration is condensed and clearly written, and has a good index

MISCELLANEOUS

THE BOWDOIN MEDICAL ALUMNI ASSOCIATION will hold its third annual meeting in Memorial Hall, Brunswick, at 12 M , June 23

ELECTROLYSIS FOR STRICTURE OF THE URETHRA It is said that a special department for the treatment of stricture by electrolysis is now being organized at St Peter's Hospital for Urinary Diseases, in London

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY, FROM JUNE 5 1886, TO JUNE 11 1886

Col J H Baxter, Chief Medical Purveyor, ordered to proceed to New York City on public business, and on the completion thereof to return to his station (S O 128, A G O , June 3, 1886)

Lieut Col Charles Page, Surgeon, granted leave of absence for one month, with permission to apply for ten days' extension (S O 55, Dept Mo , June 1, 1886)

Major Blencowe E Fryer, Surgeon, sick leave of absence still further extended six months on surgeon's certificate of disability (S O 131, A G O , June 7, 1886)

Major Henry R Tilton, Surgeon, ordered for duty as Post Surgeon, Presidio of San Francisco, Cal (S O 38, Dept Cal , June 1, 1886)

Capt G W Adair, Asst Surgeon, granted leave of absence for two months to take effect when his services can be spared (S O 128, A G O , June 3, 1886)

Capt W F Carter, Asst Surgeon, ordered for duty (temporary) at Ft Concho, Texas

Par 2, S O 55, Dept Texas, c s , granting Asst Surgeon Carter leave of absence for one month, is revoked (S O 64, Dept Texas, June 1, 1886)

First Lieut B S Black, Asst Surgeon, ordered for duty at Ft Stockton, Tex (S O 64, Dept Texas, June 1, 1886)

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U S MARINE HOSPITAL SERVICE FOR THE THREE WEEKS ENDED JUNE 14 1886

Mead, F W , P A Surgeon, granted leave of absence for twenty days June 9, 1886

Guitéras, John, P A Surgeon, granted leave of absence for thirty days June 14, 1886

Watkins, R B , Asst Surgeon, granted leave of absence for thirty days June 4, 1886

Pettus, W J , Asst Surgeon, to proceed to Charleston, S C , for temporary duty June 11, 1886

CORRIGENDA

In THE JOURNAL for May 29 p 605 the name of C W Day is given as the member of the committee on State Medicine from Louisiana It should have been Richard H Day of Baton Rouge, La In the same journal on page 600 the title of Dr A R Robinson is given as Lecturer ' when it should have been Professor of Dermatology and Syphilis

ADDRESS

IN OPHTHALMOLOGY, OTOLOGY, AND LARYNGOLOGY

Delivered at the Thirty-Seventh Annual Meeting of the American Medical Association on Tuesday, May 5, 1886

BY EUGENE SMITH, M D ,

OF DETROIT MICH , CHAIRMAN OF THE SECTION

In obedience to the established rule, providing that the Chairman of each Section shall read an address on the advances and discoveries of the past year in the branches of science included in his Section, I offer the following

A retrospect for the past year will bring to our attention but little that is new No startling discoveries have been made, no brilliant inventions heralded to the ophthalmological, otological or laryngological world, but our specialists have been far from stationary Solid advances have been made in improving upon known methods of treatment, and confirming the value of known remedies

It is now about two years since hydrochlorate of cocaine was given to the medical profession as a local anæsthetic of mucous membranes It immediately marked a new era in ophthalmological surgery, and prolonged experience has not lessened one iota of the enthusiasm which was excited by its marvelous effects

On September 11, 1883, there was published in THE JOURNAL an article on "Jequirity in the Treatment of Trachoma," of which I was the author Much has been written since that time, and, as is generally the case with new remedies, it has been exalted as a specific, and decried as a dangerous good for nothing That it has appeared to be both, I do not doubt, but to the man who has met with unusual success with it, and had succeeded by its use in getting rid of severe cases of trachoma and sequellæ, which had for months resisted all forms of treatment, in other lands as well as his own, something, more than mere detraction of its merits by some, good men though they be, will be necessary to cause its removal from the armamentarium of the ophthalmologist My own experience with it, in hospital and private practice, enables me to endorse all that has been said in its praise Owing to the peculiar susceptibility of some patients it seems best in cases wherein dense pannus does not exist to feel the way, as it were, by noting first the effect of a 1 per cent solution before resorting to a 3 per cent which seems to be the strongest solution necessary

The method of "Blepharoplasty without a Pedicle," suggested by Dr Wolfe, of Glasgow, some years since, has had several proofs the past year of its preference to older methods, several successful cases having been recorded in this country

Transplantation of the conjunctiva of the rabbit to man in suitable cases of symblepharon, also I believe, suggested by Wolfe, of Glasgow, must take its place among the recognized operations

I have had the pleasure of reporting a successful case of this character to the Section

The question of the genesis of sympathetic ophthalmia has been very thoroughly discussed and experimented upon The bulk of evidence tends to prove that inflammation of the fellow eye is produced through the track of the optic nerve and chiasma, and not only through the optic sheaths but also by the optic nerve itself

Many reports have been made the past year favorable to the artificial ripening of cataract by Forster's method of kneading the lens after iridectomy or paracentesis of the cornea Some diversity of opinion exists as to whether it offers any advantages over the old method of puncture of the lens capsule

Suppuration of the cornea after an extraction of cataract has become an exceptional occurrence, as has also grave iritis Can this be due to better methods of operating, to choice of cases for operation, to a better preparation of doubtful cases previous to operation, or to antisepsis? To whatever cause it may be attributed, knowing the serious results that are liable to be produced by septic matter, it is our imperative duty to exclude such agents as far as possible, and the antiseptic system, when used should be used in addition to, *not as a substitute for*, preventive precautionary attention

Antisepsis has been carried so far as to wash out the anterior chamber by means of a syringe and mercurial solution, after extraction of cataract, and in cases of hypopion keratitis A dressing of iodoform, used by dusting on the wound, after extraction is another method in use to prevent suppuration of the cornea. Still another is the use of antiseptic discs of gelatine which are placed on the cornea to cover the wound, prevent infection and promote coaptation and healing They adhere to the cornea and dissolve in ten or twelve hours, at the end of which time union of the wound has generally taken place

As cleanliness is the principal object sought with antiseptic lotions, many ophthalmic surgeons discard their use believing they get as good results by having instruments and dressings clean

Cocaine has taken its place in the treatment of painful affections of the ear, and in many cases is found very efficacious Two per cent or 4 per cent solutions are the ones usually employed Disagreeable symptoms—faintness and dizziness—have followed its use in several cases

Many interesting reports of cases of ear disease have been made during the past year, perhaps none among them are of more interest to members of this Association than those referring to deafness following mumps No doubt many cases are overlooked, and probably many cases of unilateral deafness, the direct cause of which is unknown, date their origin from an attack of mumps Cases are on record where the deafness occurred two or three days before the attack of parotitis, but generally the aural trouble occurs several days after The ear trouble is usually ushered in with rushing, hissing noise accompanied by more or less pain in the ear Later vertigo, nausea and vomiting set in These cases are generally considered irremediable, though recovery generally takes place

The pathological changes probably consist in an exudation into the labyrinth with subsequent atrophy —changes resembling those occurring in the testicle in attacks of mumps A Dreyfuss, (in the *Gazette Hebdomadaire*), thinks that in these cases we have to deal with a localization (metastasis) of the morbid products independent of the usual limits of parotitis Not only the lymphatic salivary and seminal glands, but the organs of special sense are affected in mumps

The dry treatment of suppurative otitis media, which has been so strongly advocated by some aurists is found to be admirable in some cases and not at all appropriate in others

The department of laryngology has steadily progressed during the year Not only has the physiology of the upper air passages been greatly elucidated, but the knowledge of the pathology and therapeutics of this region has been very much enlarged Among the important results of all this study and observation may be mentioned the discovery of the causal relations of the nasal chambers and larynx to pulmonary diseases and nervous affections Notably, certain forms of asthma, chorea, and epilepsy, and their relief through the agency of skillful local treatment

In the domain of therapeutics, laryngology has not been behind the other departments of medical science, as attested by the extensive application and brilliant achievements of the galvano cautery and wire snare for the removal of adventitious tissue, neoplasms, etc , and of cocaine and other drugs, through the medium of sponges, inhalations, etc

Many ingenious devices and instruments have also been produced for the more perfect application of medicaments through inhalation to the respiratory passages, with a marked success over former times, and as the work is still actively going on in this direction, we may look forward to the attainment of still greater results in the near future

During this year the practice of intubation of the larynx has been revived, and practised with results—according to recorded cases—which are truly marvelous, and which bid fair to, in a great measure, supplant tracheotomy for the relief of many cases of tracheal diphtheria and allied conditions For this the profession is indebted chiefly to Dr O'Dwyer, of New York

There have been several cases of excision of the larynx during the year, with little better than usual termination Great improvement has been made in photographing the laryngeal image

Particularly gratifying to the profession is the fact that in the marked progress of laryngology during the year, American laryngologists have done their full share

It is my conviction that the mission of our Sections has been largely misunderstood by the profession at large, and by the members who identify themselves with a particular Section Let me speak of my own Section, and possibly my remarks may have some bearing on others The Section is entirely given over to specialists, who, preparing papers which they know are to be heard by specialists, are apt to be technical, and the papers of interest only to such as are exclusively engaged in treating diseases of the eye, ear, or throat The general practitioner, and the bulk of this great Association, is such, not being very well posted in the technicalities of either of the branches of our Section, when he does wander into our apartments finds the proceedings so uninteresting and hard to understand that he seldom tries it the second time

Now it is a well known fact that the busy general physician in small cities and towns can not always avail himself of the counsel and assistance of a specialist, and he is obliged to treat many cases against his wishes While the improvements in the special treatment of cases usually given over to the specialist are many times so frequent that a busy practitioner cannot keep pace with them How can this state of things be obviated? I mean this condition of some of the Sections which seems to keep the mass of practitioners away from them? I would suggest that our rules be changed so as to have read before the general assembly one or more papers each day from the various Sections, said papers to be not over twenty minutes long, and upon a subject of general interest, for example, ophthalmia neonatorum, earache in children, diphtheria, the subject and reader to be chosen by the Section The papers can be discussed in the general meeting, or discussion of the subject may be relegated to the Section Some such course as this would do away with the reading of papers in a certain Section which rightfully belongs to some other, as has repeatedly happened

In conclusion, Mr President and members of the American Medical Association, let me say regarding the literature of ophthalmology, otology and laryngology, if by any chance our relations of amity should be severed from all other nations, American authors would supply the text books required by its students in the pursuance of these studies, as well as all others pertaining to the science of medicine

THE INTRA-UTERINE STEM IN THE TREATMENT OF FLEXIONS[1]

BY A REEVES JACKSON, A M , M D ,

PROFESSOR OF GYNECOLOGY IN THE COLLEGE OF PHYSICIANS AND SURGEONS OF CHICAGO ETC

As medical practitioners we all come, sooner or later, to attach more importance to the results of our individual experiences in practical matters than we do to those of others, that is to say, as we exercise more and more our powers of observation we are likely to feel a constantly increasing degree of confidence in their accuracy This may not seem modest or wise, and may even be an obstacle in the way of progress in the acquisition of knowledge But these considerations are not to the point, and I shall not discuss them I only desire to announce the fact And, knowing this, I shall not expect that the facts which I have to offer for consideration, or the arguments based upon them, will have so much influence upon others as they have upon myself

I began to treat uterine flexions with the stem pessary in the year 1870 Prior to that time the only methods I had employed were gradual dilatation and incisions The results obtained were not satisfactory Some of the cases treated by dilatation were benefited for a time, but those which were of long standing, and presumably accompanied by much textural alteration, almost invariably relapsed, unless pregnancy subsequently occurred In two of the cases in which I incised the cervix the operation was followed by pelvic inflammation, and in one of them the woman barely escaped with her life I felt the need of, and sought for a safer and more successful method I had received the impression that the treatment by intra uterine stems was more hazardous than either of the others, and although I could not understand why this should be so, I accepted the teaching, and commenced their use with great misgiving At first I did not rely upon the stem wholly, but preceded its use with moderate dilatation, or with incision In two of the cases in which this mixed method was employed pelvic cellulitis resulted—one of them terminating in abscess In not a single instance in which the stem alone has been used has recognizable inflammation occurred, although it has seemed imminent in two or three

Within the past few years observations have been published (Vedeler, Herman,) showing that ante flexion of the uterus is a frequent and normal condition, that it bears no causative relation to the symptoms usually ascribed to it, and that, hence, flexions, as such, do not demand treatment at all

While it may be admitted that all cases of uterine flexion are not accompanied by dysmenorrhœa or sterility, and that both these conditions are frequently attributable to other causes even when co existent with flexion, yet it is equally true that in very many instances there does exist a relationship of cause and effect between the flexion and the symptoms named In these, certainly, the flexion must be looked upon as a mischievous pathological factor, and one which ought to be corrected And I know—so far as I can say I know anything—that very many of them are amenable to successful treatment

I have never attempted to treat any case of uterine flexion which was not accompanied by dysmenorrhœa, and the removal of this symptom was the principal, and sometimes the only, object in view—although co existing barrenness frequently constituted an additional incentive to the patient to undergo efforts at cure

I have used several forms of stem pessary, but as most of them have been abandoned for various reasons, I need not consume time by mentioning them in detail More than any other I have used, and still use, the Chambers bifurcated vulcanite instrument, and this has been the most satisfactory A radical defect, however, of the instrument as commonly used is the divergence of the branches *below* the internal os uteri This produces an undue degree of stretching of the parts, resulting sometimes in irritation and expulsive pains I have frequently secured the retention of the instrument by approximating the branches, and using it as a single stem when it could not be borne with the branches separated In all cases the stem ought to be practically single below the internal os Above this point a slight bulging may be given to the blades near their tips, thus preserving the self retaining feature of the instrument

The details of the method which I employ latterly are as follows After ascertaining the existence and direction of a flexion I endeavor to pass a flexible olive tipped bougie through the bent portion and, if possible, quite to the fundus The depth of the uterine canal is carefully noted I then select a pliable stem having the same diameter as that of the bougie, and one third of an inch shorter than the ascertained depth of the uterus The os uteri being then exposed by means of a speculum, the stem, either seized with dressing forceps or mounted upon the end of a piece of pointed wire, is passed entirely into the uterus A large flattened tampon of absorbent cotton, moistened with slightly alumized glycerine, is then pressed firmly against the bulb of the stem, and allowed to remain one or two days It is then removed and replaced by a fresh one It may be necessary to reapply the tampon three or four times before the tendency of the stem to slip out of place disappears

If the os uteri be found pointing high up, either forwards or backwards, it may be impossible to introduce the pessary through a valvular speculum In such a case the patient should be placed in the semiprone position of Sims, or, as I prefer, in that of Simon, on the back, with the buttocks projecting beyond the edge of the table, or bed With perineum retracted, the cervix may be drawn towards the vulva with hook forceps, and the stem introduced as above described These cases present rather more difficulty at this stage of the treatment, but, as a compensation, the stem very rarely leaves its place

These flexible stems are made by cutting the distal end from the ordinary bougies used for stricture of the male urethra A shoulder or bulb is provided by rolling upon the stem a section of rubber tubing

---

[1] Read before the Chicago Medical Society June 7 1886

After the yielding stem has remained for a period varying from one to three weeks, according to the degree of tolerance manifested by the uterus, it is removed, and a thicker one put in its place This, likewise, is permitted to remain a week or two, and is then replaced by a Chambers stem, which, after the preliminary treatment described, rarely produces irritation I never expect much, if any, change of shape to occur in the uterus in consequence of the use of the flexible stem, and yet in several instances I have been surprised to discover that a very considerable alteration had taken place within a few weeks, or even a few days, after beginning its use Moreover, in a few cases I have not been obliged to resort to a rigid instrument at all, the acuteness of the flexion having been converted into a slight curvature by the use of the pliable instrument alone Usually, however, not only have I found it necessary to use an inflexible, or nearly inflexible, pessary, but to persevere in its use for periods varying from three months to a year This is not done continuously, however I always remove the pessary at the end of three or four months Of course, the uterus is found straight at this time The patient is permitted to go without the stem for at least a week, at the end of which time I make an examination to ascertain the condition of the uterus If it be found still of proper shape the pessary is not re-introduced I do not feel at all certain, however, that the apparent cure after so brief a period will be permanent, and, if practicable, I like to make another examination after the further lapse of two or three weeks In case the examination reveal a return of the distortion, even in slight degree, the stem is replaced and the patient directed to wear it for another period of two or three months, when the effect of the treatment is again tested

The feature of this treatment which I hold to be necessary to its safety and success, is its slow and gradual conduct, and the non observance of this necessity has been, I believe, the cause of dangerous results and a failure to cure A moment's consideration ought to assure us that an amount of force necessary to suddenly straighten a chronically flexed uterus would be as great as would be needed to bend a straight one, and could not be safely applied to the exterior of the organ, were that possible, much less to its delicately organized interior Any method of treatment which contemplates the very rapid restoration of a flexed uterus, is faulty in principle and dangerous in practice The distorted viscus must be coaxed, as it were, into proper shape, and then permitted to grow into normal symmetry

The drawbacks to this method of treating uterine flexions are fourfold 1 Difficulty of retaining the instrument in position 2 Pain 3 Hæmorrhage 4 Pelvic inflammation The three latter are common to all other modes of treatment

1 *Difficulty of Retention* —In nearly all cases there is a tendency on the part of the uterus to expel the foreign body, and this tendency is in direct proportion to the degree of irritation produced by its pressure—modified, however, by the relative sensitiveness or excitability of the uterus In some cases an intra uterine stem will give rise to most intense expulsive efforts at riddance, while in others its presence will be apparently unheeded, but even in some of the worst of these tolerance becomes established after a few days of rest in bed, and use of the tampon.

Occasionally, even when the uterus appears quite tolerant of the presence of its tenant, the latter will slip out almost as quickly as it is introduced I have not found any entirely satisfactory method of preventing this The best, so far, has been the use of a vaginal pessary which maintains the uterus in a position of a strong ante- or retroversion, and thus brings the bulb of the stem to rest against the vaginal wall

2 *Pain* —In my experience, pain in any considerable degree has not been a frequent or formidable symptom When it is manifested I rarely do anything to lessen it beyond enjoining strict rest in bed Regarding it as an indicator of the amount of local disturbance the stem may be causing, I prefer to not abolish it by the use of opiates, and thus mask possible inflammatory mischief Commonly, pain which early follows the insertion of the stem subsides after a day or two If it persists longer, or becomes worse, I at once remove the instrument for a few days and then re-introduce it It may sometimes be necessary to thus remove and replace it several times before it can be finally left

3 *Hæmorrhage* —This is a frequent consequence of the use of the stem I have known a few cases in which it was produced almost immediately after the introduction of the instrument and continued as long as the latter remained In most instances, however, we need not expect more than a slight flow, lasting a few days, and perhaps an earlier appearance of the next menstrual epoch, with, possibly, an increased amount of discharge during the first two or three periods following the beginning of the treatment

4 *Pelvic Inflammation* —As already stated, this has not occurred in my experience as a result of the use of the stem pessary But the fact has not lulled me into an unwarranted security against its liability to appear, and I find myself always looking for it

The following table comprises the details of sixty four cases of flexion of the uterus treated with the intra uterine stem, and shows the ages and social condition of the patients, the number of children borne by them, the direction of the flexion, and the result of the treatment, so far as known

TABLE OF SIXTY-FOUR CASES OF FLEXION OF THE UTERUS TREATED BY THE INTRA UTERINE STEM

No	Age	Social Condition	Direction of Flexion	Children	Result	Remarks
1	39	Married	Retroflexion	6	Unknown	
2	27		Anteflexion		"	
3	29		Retroflexion	3		
4	30		Anteflexion		Cure	Pregnancy followed child at term

63	24		Anteflexion			
64	20	Single	"			

From the foregoing table it will be observed that of the sixty four cases, forty-two occurred in married and twenty two in single women Of the former, eight had borne children, the other thirty-four were sterile Of the latter eight subsequently were fruitful Of the entire number a cure of the flexion followed in forty, four were improved and relieved of dysmenorrhœa, which before had been constant In twenty the result was unknown The ages of the patients ranged from 19 to 39 years The uterus was anteflexed in fifty, and retroflexed in fourteen

I believe the principle of the intra uterine stem in the treatment of flexions to be correct, and it need not be dangerous—at least no more dangerous than any other effective method I further believe that by its use a larger number of cases of uterine flexion can be cured than by any other means at present in vogue The conditions necessary for safety and success are watchfulness, patience, and slow progress

MEDICAL PROGRESS.

PHYSIOLOGICAL EFFECTS OF MASSAGE —DR F GOPADZE has published a series of observations undertaken with a view to determine the effect of massage on the transformation of the nitrogenous principles of food He has investigated the history of the subject, and finds traces of it in a Chinese work 3000 B C Dr Gopadze finds that though there has been a general tendency amongst authors to assume that massage increases the assimilative power, no exact observations on the subject have hitherto been published He therefore obtained the co operation of four medical students, who for three consecutive weeks became inmates of Professor Manassein's clinic, and lived on certain articles of food—bread, milk, soup, veal, and roast beef, the quantities injested being accurately noted The nitrogen in all the samples of food, and in the fæces and urine excreted, was determined by the Kjeldahl-Borodin process Massage was practised for from twenty to twenty five minutes once a day two or three hours after food The operations were commenced by *effleurage*, beginning from the extremities and working towards the centre This was followed by *massage a friction*, *pétrissage*, *tapotement*, a second *effleurage* of each part concluding the whole The temperature was subsequently taken, and in some cases sphygmographic tracings In all four cases the appetite was decidedly increased, not only during the week in which massage had been practised, but after it had been stopped, thus, one of the subjects took an average daily quantity of 24 95 grammes of nitrogen during the first week, 30 97 during the second or week of massage, and 29 57 during the third week Similarly the amount of nitrogenous transformation was augumented during the continuance of massage in all four cases The augumentation persisted in two of the cases, but in the other two the transformation was less during the third than during the first week In case 1 the nitrogenous transformation was increased 3 per cent during the second week and 1 per cent during the third In case 2 it was increased 1 per cent during the second week, but diminished 11 per cent during the third In case 3 it was increased 3 per cent during the second week, but diminished 10 per cent during the third In case 4 it was increased 4 per cent in the second week, and 3 per cent in the third The quantity of nitrogen assimilated increased in all four cases, independently of the amount of food ingested During massage two of the subjects gained slightly in weight, the other two losing weight, but during the week following the one in which massage was practised all four gained The axillary temperature decreased for about half an hour after the operation to an extent varying from 0 1° to 0 5° C after which it began to rise, attaining its original figure, or from 0 1° to 0 3° below it, about an hour after the end of the *seance* The respirations became more frequent, and were of a deeper character The effect on the pulse varied with the character of the massage When this was carried on lightly, the pulse became more frequent, but when the manipulation the male urethra A shoulder or bulb is provided by rolling upon the stem a section of rubber tubing

After the yielding stem has remained for a period varying from one to three weeks, according to the degree of tolerance manifested by the uterus, it is removed, and a thicker one put in its place This, likewise, is permitted to remain a week or two, and is then replaced by a Chambers stem, which, after the preliminary treatment described, rarely produces irritation I never expect much, if any, change of shape to occur in the uterus in consequence of the use of the flexible stem, and yet in several instances I have been surprised to discover that a very considerable alteration had taken place within a few weeks, or even a few days, after beginning its use Moreover, in a few cases I have not been obliged to resort to a rigid instrument at all, the acuteness of the flexion having been converted into a slight curvature by the use of the pliable instrument alone Usually, however, not only have I found it necessary to use an inflexible, or nearly inflexible, pessary, but to persevere in its use for periods varying from three months to a year This is not done continuously, however I always remove the pessary at the end of three or four months Of course, the uterus is found straight at this time The patient is permitted to go without the stem for at least a week, at the end of which time I make an examination to ascertain the condition of the uterus If it be found still of proper shape the pessary is not re-introduced I do not feel at all certain, however, that the apparent cure after so brief a period will be permanent, and, if practicable, I like to make another examination after the further lapse of two or three weeks In case the examination reveal a return of the distortion, even in slight degree, the stem is replaced and the patient directed to wear it for another period of two or three months, when the effect of the treatment is again tested

The feature of this treatment which I hold to be necessary to its safety and success, is its slow and gradual conduct, and the non observance of this necessity has been, I believe, the cause of dangerous results and a failure to cure A moment's consideration ought to assure us that an amount of force necessary to suddenly straighten a chronically flexed uterus would be as great as would be needed to bend a straight one, and could not be safely applied to the exterior of the organ, were that possible, much less to its delicately organized interior Any method of treatment which contemplates the very rapid restoration of a flexed uterus, is faulty in principle and dangerous in practice The distorted viscus must be coaxed, as it were, into proper shape, and then permitted to grow into normal symmetry

The drawbacks to this method of treating uterine flexions are fourfold 1 Difficulty of retaining the instrument in position 2 Pain 3 Hæmorrhage 4 Pelvic inflammation The three latter are common to all other modes of treatment

1 *Difficulty of Retention* —In nearly all cases there is a tendency on the part of the uterus to expel the foreign body, and this tendency is in direct proportion to the degree of irritation produced by its pressure—modified, however, by the relative sensitiveness or excitability of the uterus In some cases an intra uterine stem will give rise to most intense expulsive efforts at riddance, while in others its presence will be apparently unheeded, but even in some of the worst of these tolerance becomes established after a few days of rest in bed, and use of the tampon.

Occasionally, even when the uterus appears quite tolerant of the presence of its tenant, the latter will slip out almost as quickly as it is introduced I have not found any entirely satisfactory method of preventing this The best, so far, has been the use of a vaginal pessary which maintains the uterus in a position of a strong ante- or retroversion, and thus brings the bulb of the stem to rest against the vaginal wall

2 *Pain* —In my experience, pain in any considerable degree has not been a frequent or formidable symptom When it is manifested I rarely do anything to lessen it beyond enjoining strict rest in bed Regarding it as an indicator of the amount of local disturbance the stem may be causing, I prefer to not abolish it by the use of opiates, and thus mask possible inflammatory mischief Commonly, pain which early follows the insertion of the stem subsides after a day or two If it persists longer, or becomes worse, I at once remove the instrument for a few days and then re introduce it It may sometimes be necessary to thus remove and replace it several times before it can be finally left

3 *Hæmorrhage* —This is a frequent consequence of the use of the stem I have known a few cases in which it was produced almost immediately after the introduction of the instrument and continued as long as the latter remained In most instances, however, we need not expect more than a slight flow, lasting a few days, and perhaps an earlier appearance of the next menstrual epoch, with, possibly, an increased amount of discharge during the first two or three periods following the beginning of the treatment

4 *Pelvic Inflammation* —As already stated, this has not occurred in my experience as a result of the use of the stem pessary But the fact has not lulled me into an unwarranted security against its liability to appear, and I find myself always looking for it

The following table comprises the details of sixty four cases of flexion of the uterus treated with the intra uterine stem, and shows the ages and social condition of the patients, the number of children borne by them, the direction of the flexion, and the result of the treatment, so far as known

TABLE OF SIXTY-FOUR CASES OF FLEXION OF THE UTERUS TREATED BY THE INTRA UTERINE STEM

61	20	Single			Cure	
62	28	Married	Retroflexion			
63	24		Anteflexion			
64	20	Single				

From the foregoing table it will be observed that of the sixty-four cases, forty-two occurred in married and twenty two in single women Of the former, eight had borne children, the other thirty-four were sterile Of the latter eight subsequently were fruitful Of the entire number a cure of the flexion followed in forty, four were improved and relieved of dysmenorrhœa, which before had been constant In twenty the result was unknown The ages of the patients ranged from 19 to 39 years The uterus was anteflexed in fifty, and retroflexed in fourteen

I believe the principle of the intra uterine stem in the treatment of flexions to be correct, and it need not be dangerous—at least no more dangerous than any other effective method I further believe that by its use a larger number of cases of uterine flexion can be cured than by any other means at present in vogue The conditions necessary for safety and success are watchfulness, patience, and slow progress

MEDICAL PROGRESS.

Physiological Effects of Massage —Dr F Gopadze has published a series of observations undertaken with a view to determine the effect of massage on the transformation of the nitrogenous principles of food He has investigated the history of the subject, and finds traces of it in a Chinese work 3000 B C Dr Gopadze finds that though there has been a general tendency amongst authors to assume that massage increases the assimilative power, no exact observations on the subject have hitherto been published He therefore obtained the co operation of four medical students, who for three consecutive weeks became inmates of Professor Manassein's clinic, and lived on certain articles of food—bread, milk, soup, veal, and roast beef, the quantities injested being accurately noted The nitrogen in all the samples of food, and in the fæces and urine excreted, was determined by the Kjeldahl-Borodin process Massage was practised for from twenty to twenty five minutes once a day two or three hours after food The operations were commenced by *effleurage*, beginning from the extremities and working towards the centre This was followed by *massage a friction*, *pétrissage*, *tapotement*, a second *effleurage* of each part concluding the whole The temperature was subsequently taken, and in some cases sphygmographic tracings In all four cases the appetite was decidedly increased not only during the week in which massage had been practised, but after it had been stopped, thus, one of the subjects took an average daily quantity of 24 95 grammes of nitrogen during the first week, 30 97 during the second or week of massage, and 29 57 during the third week Similarly the amount of nitrogenous transformation was augumented during the continuance of massage in all four cases The augumentation persisted in two of the cases, but in the other two the transformation was less during the third than during the first week In case 1 the nitrogenous transformation was increased 3 per cent during the second week and 1 per cent during the third In case 2 it was increased 1 per cent during the second week, but diminished 11 per cent during the third In case 3 it was increased 3 per cent during the second week, but diminished 10 per cent during the third In case 4 it was increased 4 per cent in the second week, and 3 per cent in the third The quantity of nitrogen assimilated increased in all four cases, independently of the amount of food ingested During massage two of the subjects gained slightly in weight, the other two losing weight, but during the week following the one in which massage was practised all four gained The axillary temperature decreased for about half an hour after the operation to an extent varying from 0 1° to 0 5° C after which it began to rise, attaining its original figure, or from 0 1° to 0 3° below it, about an hour after the end of the *seance* The respirations became more frequent, and were of a deeper character The effect on the pulse varied with the character of the massage When this was carried on lightly, the pulse became more frequent, but when the manipulation was more forcible, the pulse became slower The effects in both cases persisted for an hour or more after the termination of the operation In conclusion, the author suggests that massage should prove useful in chronic gastro intestinal catarrh, in chronic constipation due to an atonic condition of the intestines, also in various cases where there is a lack of tone in the abdominal muscles He also thinks that the practice of massage should be a subject of instruction not only in the Military Medical Academy of St Petersburg, but in all the medical faculties of the empire and in the institutions for training "feldshers"—a semi educated class of men who act as hospital sergeants, and after retiring from the army are put in charge of village communities where there is no medical man —*Lancet*, May 22, 1886

THE RADICAL CURE OF VARICOCELE —To the large number of operations which have been devised for the cure of varicocele yet another has been added by M RICHET, of the Hôtel Dieu It is described in *Revue de Chirurgie* for April by Mr Picqué who is disposed to laud it The vas deferens is first separated from the bundle of veins to be obliterated and held out of the way by a thread of copper wire passed through the scrotum in an armed needle The veins and the fold of scrotum over them are then grasped by the blades of forceps heated to a red heat, such as M Richet uses for the destruction of hæmorrhoids A wound of some size is left, and cicatrization is obtained in about three weeks M Picqué argues that excision of the veins is the best of all the many operations for varicocele, but that it should only be undertaken by those who are quite familiar with the aseptic treatment of wounds In cases where the surgeon is not confident of his ability to keep the wound aseptic he recommends Richet's operation We cannot join in such advice Richet's operation appears, from the description given of it, to be a very rude method of obtaining a result more easily, more quickly, and better obtained by other means —*Lancet*, May 8, 1886

TENDON-GRAFTING —A boy, aged 14, cut himself in the hand and divided both flexor tendons of the middle finger Thirteen months later he came under M PEYROT's care There was then complete inability to extend the last two joints of the finger An operation was undertaken It was impossible to approximate the divided ends of the tendons, so a piece of a young dog's tendon was interposed between them Unfortunately the wound suppurated, but cicatrization took place and partial success was attained The finger could be semi flexed, and was constantly held partly flexed and therefore less exposed to injury than before, but the tendon was adherent to the scar There seems to be no doubt that the engrafted tendon is really united to the boy's tendon —*Lancet*, May 8, 1886

MORPHINE SUBCUTANEOUSLY IN INFANTILE CONVULSIONS —DR C S SCOFIELD, of Boston, reports the case of a child eighteen months of age, previously healthy, whom he had been called to see on account of eclampsia The child had been in convulsions for two hours and had been given emetics, hot baths, and mustard to the feet, without any benefit The writer at once administered ⅛ grain of sulphate of morphine hypodermatically which was repeated at the end of twenty minutes—no effect having been produced by the first dose This was also followed by no improvement, and a third injection was administered twenty minutes later This was effectual in controlling the convulsions, and by the expiration of an hour from the time of administration of the first dose the child was sleeping quietly When seen the following morning the child had taken food as usual, and was apparently as well as ever —*Medical Record*, May 29, 1885

KOCH'S BACILLI IN ADDISON'S DISEASE —DR GOLDENBLUM, of Dorpat gives in the *Vrach*, (No 11, 1886) an account of a case of Addison's disease occurring in a young man, in which the suprarenal capsules, which were cheesy, contained Koch's bacilli The other organs of the body, including the lungs, which were emphysematous, were also examined, but no bacilli were found The suprarenal capsules were immersed in alcohol and sections made, which were stained by Ehrlich's method A previous case of Addison's disease in which Koch's bacilli were found in the suprarenal capsules was reported in the *Vrach* (No 1, 1886), but in that case the diagnosis was somewhat less clear the body not being distinctly bronzed, though a greyish discoloration was noted, there was also tuberculosis in the lung, which did not exist in Dr Goldenblum's case — *Lancet*, April 24, 1886

HOW TO DETECT ACETONE IN URINE —It is stated by MONS P CHAUTARD that the presence of acetone in urine or pathological liquids may be readily detected by adding a drop of an aqueous solution of magenta decolorized by sulphurous acid to the suspected liquid, when, if acetone is present, a violet color is produced, the intensity of which is proportional to the amount present In dilute solutions the coloration does not appear until after four or five minutes, if the amount of acetone is very minute, the urine or other liquid may be distilled, the first portion that comes over being examined In this way a very minute proportion of acetone may be detected —*Lancet*, May 15, 1886

A LOTION FOR PITYRIASIS CAPITIS —VIGIER (*Gaz Hebdom de Med et de Chir* , April 2, 1886) recommends the following lotion for pityriasis of the scalp and to arrest incipient baldness

Alcohol		3 ounces
Spirit of camphor,	each	75 grains
Rum,		
Tincture of cantharides,		
Glycerin,		
Essence of sandal wood,	each	5 drops
Essence of wintergreen,		
Essence of roses,		
Essence of laurel		
Hydrochlorate of pilocarpine		7½ grains

Dissolve the pilocarpine in the alcohol, and add the other ingredients To be lightly rubbed on the scalp once a day

—*New York Medical Journal*, May 1, 1886

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No 65 RANDOLPH STREET
CHICAGO, ILLINOIS

SATURDAY, JUNE 26, 1886

CLOSE OF VOLUME VI

The present number of THE JOURNAL closes the sixth volume, and the third year of the publication of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION When the first number was issued in July, 1883, the mail list contained less than 2,500 names of members and subscribers, and now it contains about 4,500 The steady increase in the list of its readers, and corresponding increase of revenue, has enabled us to employ more editorial and other assistance, and to give THE JOURNAL a character for neatness, promptness of issue, and value of contents second to no other medical journal in this country Now is a good time for our friends to send in names of new subscribers or of members of the Association by application, as the next number will commence Volume VII Every dollar added to the income will be faithfully applied in such manner as to add to the interest and value of THE JOURNAL for the coming year

WIRING AND GALVANIZATION IN ANEURISM

The results of the treatment of aneurism by electrolysis or the introduction of foreign bodies, such as wire, horse-hair and catgut, have not been very encouraging thus far Ciniselli has recorded 37 cases of aortic aneurism treated by electrolysis, with 6 cures, but his statistics differ so widely from all others that they seem doubtful L H Petit gives 114 cases of aneurism of the thoracic aorta, with 69 benefited, 38 deaths, and 45 failures, but it is found that of the 69 benefited the benefit lasted only a few months in 37, and it was not greater than might have been obtained by rest

Nor has greater success been obtained by the introduction of foreign bodies In a lecture on "A Case of Thoracic Aneurism treated by a Novel Method," MR RICHARD BARWELL says that foreign bodies have been introduced eight times, and in all without success, save in a case of brachial aneurism too small to furnish any data It seems doubtful from this whether Mr Barwell has seen the report of abdominal (aortic) aneurism on which Loreta operated on December 14, 1884, by the introduction of silvered copper wire On the twenty-sixth day after the operation the tumor was solid, reduced fully one-half and the patient was going about This case, whether the patient died subsequently or not from the aneurism, may certainly be said to furnish data However this may be Mr Barwell thinks that electropuncture, when carried out so as to avoid irritation on sloughing of the sac—or so as not to be injurious —fails for the following reasons The cases in which it is used are of necessity large aneurisms, with sacs capable of containing twenty, thirty, or more ounces of blood, and into this large space from one to four needles are inserted If these be connected with the positive pole, a hard but very small clot will be formed round each needle "It seems to me that the difficulty, the rarity of success, depends on the very slight influence that one, two, or three little nodules of coagulum can have on so large a mass of blood If, now, we consider the other method, we find in all probability an opposite defect—namely, the wire or other substance occupies a considerable space in the sac, and I think there is little, if any doubt that the blood will coagulate round substances thus introduced " In this case, however, the clot is very soft —a passive clot, as Broca called it, it is unstable, and there are clinical facts to show that such a clot may be dissolved, and there is a danger that some shreds of it may be carried away as emboli

Such considerations led Mr Barwell to think that if he could increase the area of galvanic action, or increase the hardness and stability of clots formed around foreign bodies, a successful method of dealing with these large aneurisms might be found, and it occurred to him that this might be effected by introducing steel wire into an aneurismal sac, and arranging the wire so that it would lie in wide coils, after which a carefully regulated galvanic current could be passed along the wire He reports a case treated in this manner in his lecture, which may be found in *The Lancet*, of June 5, 1886 When the treatment was determined upon the patient was in a very critical state "The lungs admitted but very little air, in places none at all, his cough was very painful and constant, the expectoration frankly purulent, the wave of blood in the extra-thoracic part appeared almost subcutaneous" The patient had then been under observation for six months A tube of ivory, sharpened as a hypodermic needle, was accepted as the most feasible arrangement for the introduction of the wire The skin was rendered insensible by the injection of cocaine, "a fold was pinched up and a little incision made from within outwards over the tumor, the ivory needle was then thrust in without difficulty and about ten feet of the finest steel wire passed into the sac The wire, having been first wound on a wooden cylinder half an inch in diameter and being of the best steel, must, after being paid through the needle, coil itself up again in the sac"

The galvanic arrangement, which was under the care of Dr Murray, was as follows The wire was connected with the positive pole of an eight celled Garnet's battery, and the negative pole was applied to the upper dorsal region a little to the left of the middle line, a piece of amadou, about a foot square, saturated with hot water, being interposed between the electrode and the skin In the circuit were included a galvanoscope and a Gaiffe's voltameter As the resistance in a voltameter was so great that the strength of the current did not exceed four milliamperes, twenty cells of a Coxeter's "practitioner's voltaic battery" were added to the Garnet battery, which increased the strength of the current to nine or ten milliampères, and this was obtained during the operation, which lasted an hour and ten minutes Some redness of the skin was caused at the negative pole, but no indications of irritation at the place of puncture "For twelve hours signs of consolidation were absent, or nearly so, but at the end of the period the pulsation seemed considerably more distant and the tumor much harder, and this change rapidly increased The lungs began to unload themselves of their accumulated pus and muco-pus, expectoration, very difficult previously, became easy and somewhat copious, showing decrease of pressure on the bronchi" But on the fourth day of the operation a new tumor appeared to the right of the sternum and rapidly increased, the patient became weaker, and died a week after the operation, partly from exhaustion, and partly from rupture of the second sac

The post mortem examination showed that the operation was performed too late, and the existence of the second sac, which could not be reached by the wire, showed that under any possible circumstances the case must have ended fatally But it also showed that there is a future for this method of treating large aneurisms The first sac contained large wide coils of steel wire, each of which was surrounded by a pretty thick coat of firm colorless fibrin, strongly adherent to it at many places—"that is to say, wherever the metal was in contact, or within a moderate distance of the wall, the wire was bound to the sac by this fibrin, thus greatly increasing its strength and resistance Mr Barwell thinks that he is not too dogmatic in saying that if a galvanic current and coils of wire are to be of service in these cases, they will only be so used in combination

MEMORIAL MEETING TO DR BALDWIN —A very full and interesting meeting of the Montgomery Medical and Surgical Society, Alabama, was held on June 9, 1886, in memory of the late Dr W O Baldwin, of that city Very appropriate and interesting addresses reviewing and commendatory of the character and professional work of Dr Baldwin were made by Drs J S Weatherly, R F Michel, J B Gaston, W G Bibb, and R S Williams Letters were also read from many eminent members of the profession from all parts of the country

NINTH INTERNATIONAL MEDICAL CONGRESS

For the information of our readers, and especially to facilitate correspondence, we give the following sub committees elected by the Local Committee of Arrangements at Washington, D C

1 *Committee on Congressional Legislation* —Drs A Y P Garnett, J H Baxter, Ralph Walsh, J M Toner, —— Townsend, N S Lincoln, and C M Hammett

2 *Committee on Finance* —Drs G L Magruder, J W Bulkley, J W Bayne, J T Young, T C Smith, C V N Callan, and Z T Sowers

3 *Committee on Printing* —Drs J B Hamilton, Thomas Antisell, Ralph Walsh, W T Hord, D P Woolhaupton, and H D Fry

4 *Committee on Reception* —Drs J M Toner, I C Rosse, Louis Mackall, S O Richey, Fairfax Irwin, B O Skinner, and H B Loring

5 *Committee on Entertainment* —Drs N S Lincoln, W O Baldwin, J R Hagner, W W Godding, G W Acker, D C Patterson, and C M Hammett

6 *Committee on Transportation* —Drs J W H Lovejoy, W H Taylor, R Reyburn, Sr, Armistead Peter, Geo W Stoner, and E M Schaefer

7 *Committee on Place of Meeting for Congress and Sections* —Drs D C Patterson, Chas Smart, W H Hawkes, J F Hartigan, J O Stanton, Lachlan Tyler, and C W Franzoni

The General Officers of the Local Committee of Arrangements are A Y P Garnett, M D , Chairman, J M Toner, M D , Vice Chairman, C H A Kleinschmidt, M D , Secretary, D C Patterson, M D , Treasurer

It will be seen that the Army, Navy and Marine Hospital Service are well represented on the Local Committee, while the remaining members include a large part of the most active and influential members of the profession in Washington So early and efficient an organization of the Local Committee of Arrangements affords an additional assurance that every needed arrangement will be made in Washington for the comfort of members and the complete success of the Congress

THE TITLE OF SECTION XV of the Ninth International Medical Congress has been changed, at the suggestion of its President, Dr Gihon, from "Collective Investigation, Nomenclature, Vital Statistics, and Climatology," to "*Medical Climatology and Demography*"

SOCIETY PROCEEDINGS

CHICAGO MEDICAL SOCIETY

Stated Meeting, June 7, 1886

THE PRESIDENT, E J DOERING, M D ,
IN THE CHAIR

DR A REEVES JACKSON read a paper entitled

THE INTRA UTERINE STEM IN THE TREATMENT OF FLEXIONS

(See page 703)

DR DANIEL T NELSON, in opening the discussion, said that he was glad to have heard the paper, and thought it was a most valuable one The cautions that it gives are certainly those that all of us should remember, to wit the length of the instrument used compared with the length of the uterus, the slow and gradual dilatation of the uterus before using the inflexible stem, and removing it on the occurrence of bad symptoms In recent years I have not been in the habit of using the stem pessary as much as my friend Dr Jackson, but I think that with his present instructions, I shall try it again Not that I have not tried gradual dilatation, and the gradual, slow, careful straightening of the uterus, but I have not by this particular means caused the pessary to be retained as constantly as he has The vulcanite pessary, and the various other forms, including the Wright's or Chambers s modification, I have used, and with many of the difficulties the doctor has narrated But with his modification it seems to me very likely we can use them with better success The irritation produced by them has been a great drawback, and in recent years it has been my habit rather to use the form of pessary recommended by one of our members, Dr W H Byford, the slippery elm bougie It produces a gradual dilatation of the uterus, and often produces remarkable results in the treatment of the flexions, and I have had no bad results from its use One point that the doctor did not emphasize sufficiently is that the instrument should not be retained long if it produces pain, but it should be removed and the patient put in bed I should have preferred to have him give directions for the patient to remove the instrument if the pain continued for a long time, for if it does the instrument ought to be removed, and if he should happen to be out of the city and the patient should be unwilling for any one else to see her, serious disease might commence before he returned and removed the instrument For this reason it is, and always has been, my plan to have the instrument so arranged, by a string or something of that sort, that the patient can remove it herself We should remember that the instrument should be less than the uterus by a third of an inch, that the uterus is to be put into its proper shape, in a splint, as it were, and then expected to grow right—that it is not cured when it is straightened—if it has been displaced for a considerable time there has been an atrophy of the uterine tissue on one side, and it may take weeks, or perhaps months, to alter the nutrition' of the different parts of the organ, and until that change has taken place it is not likely that the patient is permanently cured, unless pregnancy has taken place, and altered the nutrition of the parts As to pelvic inflammation, the author has been more fortunate than most of us in the use of stem instruments One point I wish to add, viz that when there is any possibility of gonorrhœal poison lurking in the genital passages of the female, greater care should be taken in the use of such instruments, or operative procedure of any sort, for that matter I feel, when there is reason to suspect that this poison has once been implanted, that I hardly dare to introduce sound, pessary, or other instrument in the interior of the uterus, and believe that such an instrument should be used with the greatest caution in these cases

DR E C DUDLEY said The marvelous freedom from dangerous inflammation in treating uterine flexure by forcible dilatation and by the intra-uterine stem, furnishes a striking illustration of the fact that the human uterus will sometimes endure an immense amount of abuse My own preference is generally for the former method, as advocated by Goodell, Ellinger, and others My experience has only tended to confirm me in the impression that forcible dilatation is reasonably satisfactory in its results, and that the results are reasonably permanent I would seldom advocate the use of intra uterine stem pessaries for retroflexion unless the flexure were of the so called congenital variety, and therefore associated with atrophy of the uterus, a condition which is very rare The essayist has, perhaps for reasons of brevity, omitted to make the distinction between physiological and pathological anteflexion This distinction within a few years has been quite clearly defined by

Schultze, Fritsch, and others, and their teachings are now recognized as correct by many of the leading gynecologists throughout the world In the light of their investigations the old diagram of Kolrausch, which for more than twenty years has generally formed the basis for the illustrations of the normal position of the uterus, is now quite generally discarded The uterus has no absolutely fixed position, but it has a certain normal range of movements The angle between the body and the cervix may vary according to the varying quantity of material in the rectum and bladder, from zero to at least 45°, Fritsch says 90°, and his observation is possibly within the physiological limits When the bladder is full the uterus becomes straight and the angle of flexure disappears When empty the angle may measure from 45° to 90°, and yet not be pathological It is moreover probable that a flexure of much less than 45° when the bladder is empty, should be considered pathological Furthermore, anteflexion, even within the defined limits, is always pathological if there be immobility at the angle of flexure, indeed, a displacement exists whenever the organ is restrained from its normal movements In a word, anteflexion is pathological if the mobility at the angle of flexure be increased or decreased beyond the physiological limits, or absent Want of a clear understanding of these simple facts has led to the invention of innumerable pessaries for straightening the anteflexed uterus, and they have been persistently employed, to the detriment of the patient, in cases of perfectly physiological anteflexion Suppose a case The uterus is shown by digital examination to be so low in the pelvis that when the bladder is empty its entire anterior wall is easily touched The physiological flexure, which may be from 45° to 90°, is then perfectly apparent to the examining finger—the symptoms of vesical irritation are attributed to the flexure, and an anteflexion pessary is accordingly introduced which produces pressure upon the anterior wall of the uterus The symptoms disappear, and the conclusion is erroneously formed that the relief was dependent upon the straightening of the uterus, when in reality the pessary has, perhaps, produced no such effect, but has merely lifted the uterus to its health level, and thereby relieved the symptoms, which were due not to flexure but to descent The same manner of treatment has often been followed by relief from similar symptoms attributed to anteversion, when in reality the pessary, by lifting the cervix to a higher level, has exaggerated rather than reduced the anteversion For this reason all vaginal pessaries especially designed for anterior displacements are in no respect superior to the ordinary Hodge pessary, indeed, they are objectionable, because in overcoming the descent they press upon the uterine wall and thereby cause irritation of the organ Anteflexion is only a symptom which may result from any one of a variety of widely different causes, such as adhesions, uterine fibroid, parametritis posterior, or failure of the puerile uterus to develop at puberty It would indeed be irrational to attempt the relief of a symptom due to such diverse causes by any single plan of treatment The essayist would not attempt to do this, but he has neglected to specify the particular flexures for the relief of which he deems the stem applicable Inasmuch as many of these flexures are dependent upon uterine or peri-uterine inflammation, and inasmuch as there is reason to conclude that dysmenorrhœa and other evils are more the result of the inflammatory state than of the flexure itself, I would advise that the stem be reserved for cases which are not relieved after the inflammation has been removed by safer methods Such a plan would certainly restrict the use of the stem to a very small number of cases, because the symptoms for which it is to be employed would so often disappear upon the cure of the inflammation It is indeed probable that the dysmenorrhœa for which the author has employed the intra uterine stem may depend rather upon some faulty nutrition, or upon some disease of the uterus independent of the flexure, and that the stem therefor gives relief by some change which it produces in the nutrition of the organ If this be true, it would then follow that anteflexion *per se* really furnishes no positive indication either in itself or in its results, but that the same treatment would be equally effective under similar conditions without the co existing flexure Congenital anteflexion of the puerile uterus is undoubtedly a condition for which the stem may be considered one of the legitimate means of treatment Sterility, whether associated with pathological flexure or not, has been successfully treated by the stem Winckel says that the presence of the instrument may give a better development to the menstrual decidua and thereby make a better bed for the ovum One objection to the stem, strongly urged by Schultze, is that by its use the physiological flexure is overcome, and it therefore may be said to produce, rather than to relieve, displacement But we should not permit theoretical considerations to bias our judgment in face of the author's carefully observed results His contribution is certainly a valuable one, and shows that the instrument, at least in careful hands, is less dangerous than is ordinarily supposed The author's freedom from inflammatory results is doubtless due to his judicious preparation of each case by means of the olive tipped bougie Undoubtedly the observations of Dr Jackson and others must be considered as placing the intra uterine stem among the useful and approved resources in the treatment of these troublesome cases, but even at the risk of prolixity I again protest against the indiscriminate treatment of purely physiological anteflexion by any means soever

Dr H P Merriman said I have very little to add to what has been said The use of the various methods that have been proposed seem to me to aim at one given end, to change the nutrition of the uterus Forcible dilatation does that to a certain extent, it is temporary, however, in its action Incision produces an alterative effect and accomplishes its purposes It does not succeed a great many times, neither does the temporary action of dilatation The use of the stem pessary, on the other hand, succeeds because it is keeping up a continuous pressure upon the parts Now I am decidedly in favor of this treatment by stem pessary, it strikes me that it is the only rational method of treating these flexions, which are pathological After the cause of a flexion has been removed, that is, the inflammation of the uterus or the pressure of a tumor, or pressure of heavy clothing, or whatsoever causes it, the uterus does not always return to its natural state, and then we need to introduce some method for restoring it to its normal condition, and I do not know any more rational method than this one This paper strikes me as a very valuable one The valuable part of this treatment seems to me not to be so much in the use of this stiff stem, as the earlier treatment by the flexible stem, where, by continuous pressure upon the parts, we are able to accomplish the same effect as passing a sound in chronic cases of gleet, producing a healthy action in a diseased organ and thus producing absorption of a pathological exudate It strikes me that the doctor recognizes this condition for often before using the stiff Chambers' stem when he has been using these bougies, in a great many instances he has found the treatment has nearly cured the disease, and if it had been continued longer I believe a cure would have been effected The intra-uterine stem by continuous pressure induces an alterative action of the tissues, the absorption of exudates and a gradual return to the normal condition, of the uterus, and a natural tendency toward a straightening of the uterine canal as the uterus becomes healthy

Dr **Sarah H Stevenson** said I have listened to the paper with a great deal of interest, and also to the discussion My methods are different, I have used the stem pessary a great deal in former years, but for the past two years I have discarded it entirely as some of the results were unfortunate, although I think I have never had any serious results from the use of the stem I now use, and have for the past two years, the galvanic current entirely, and it is applicable to all cases, especially in those in which the stenosis is so great as not to admit the passage of the bougie I have never found a case in which I could not use this method with satisfactory results

Dr **H T Byford** said I quite agree with Dr Dudley in his trite but very true remark, "It is wonderful what an amount of abuse the uterus will stand, and I congratulate Dr Jackson that he has discarded incision and dilatation in treating flexions I also congratulate him upon his good success I believe the mortality from this treatment—the treatment by the intra uterine stem—has been estimated to be from ½ to 1 per cent by those who have investigated heretofore Whether it is so now I do not know The present per cent of inflammation of the cellular tissue varies from 2 to 5 per cent, as nearly as I can determine There are an immense number of cases in which the stem caused inflammation, which have never been published It seems to me that in considering this subject the reason for this treatment should be made more apparent There are some who use it as a splint or merely to straighten the uterus, others use it as a stimulant on account of its continuous pressure There is no doubt it stimulates and temporarily straightens the uterus, but it is well known that in time, in a large proportion of these cases, the uterus again becomes flexed The question arises, should we try to straighten the uterus? As Drs Dudley and Schultze have said, certain flexions are supposed to be physiological (which I don't believe), the uterus is supported in the neighborhood of the internal os, which may be said to have a fixed place in the pelvis The elasticity of the tissue will allow that part of the uterus to be pressed in nearly all directions, but it will come back The fundus may bend forward or backward and remain in such position for some time, and the uterus still be in a normal position During youth the child who sits too much, has a curved spine, etc, having a uterus pretty firmly fixed at the cervix, will often have the uterus pressed upon by the abdominal contents in the wrong direction The normal resistance of the uterus to flexure will be gradually overcome (the uterus may even become atrophied), and a flexion results which, when slight, may be called a physiological flexion, and may exist without causing trouble, but it is pathological The elasticity which the uterus of normally firm structure displays during the filling up and emptying of the rectum and bladder is hardly worthy of the name of flexure Any considerable permanent flexure occurring in this way must be the result of want of firmness in the structure of the uterus If we are going to use a supporter we should use it when the flexure is forming, not after it has been produced If we will use such treatment as will remove the improper pressure upon the uterus, viz by straightening up the spine, using exercise, etc, etc, a stem will be seldom necessary, because whatever flexion has already been produced will usually not cause unpleasant symptoms If it has gone to the degree of producing atrophy of the uterus we may need to use a stem pessary, but as a stimulant to the uterine tissue rather than a straightener of this organ I have seen uteri bent almost like a horseshoe become impregnated and return almost to their former degree of flexion The intra uterine stem, in view of its slight action as a support and powerful action as a stimulant, and its notoriously bad record, should be the last resort The frequency with which Winckel uses the stem is now about once in 218 cases, while formerly he used it about once in 50, and he is using it less all the time In my experience and the experience of a great many others, if we cure the acute or subacute inflammation of the uterus and then apply stimulating measures, we nearly always accomplish the cure of the flexion by safer means There are, of course, a few cases left in which the use of the uterine stem may be justifiable, but I think they are exceedingly rare If those present, following Winckel, use them only once in 218 times, but few of us will live long enough to do a great deal of harm

Dr **F Davis Fitch** said I think that a paper so commendatory of a measure as this, will perhaps lead many of the members of the profession to adopt it without proper precautions and without realizing the dangers which attend the use of the intra uterine stem I believe it is a very dangerous instrument to use I am an advocate, as you all know, of pessaries, but I do think the intra uterine stem a dangerous instrument, and that in less careful hands than Dr Jackson's serious results will often follow My own experience in the use of it has been limited for the reason that I became alarmed from the bad reports of cases by Dr Chambers himself, the inventor of this bifurcated instrument which Dr Jackson has exhibited If the same precautions are used that are advised by Dr Jackson, I think as a rule it might be entirely harmless—no, I should hardly be able to say entirely harmless, or entirely free from danger—but I think the precautions which he has adopted have been very ingenious and would in the majority of cases prevent serious results from the intra-uterine stem His use of the bougies preceding the use of the inelastic stem, accustoming the uterine mucous membrane, or the uterus itself, to the presence of a foreign body within its cavity, is very ingenious, and a thing I should never have thought of myself Although I have tried these pessaries occasionally my great difficulty has been to keep them in the uterus, I might open them in any direction I pleased, spread the blades as widely as I pleased, and they would slip out—they caused so much uterine contraction that they would be expelled from the uterine cavity into the vagina, and I have always been disappointed in the results from their use For several years while I was in active practice I had adopted the treatment of Peasley, for flexion and stenosis, whether caused by exudation or spasmodic contraction of the os internum, that is by the use of his uterotome dividing the stricture at the internal os, and then gradually dilate the canal until I could introduce a No 12 or 14 sound through the os internum This was introduced every second day from one week to two weeks until it ceased to be followed by pain, and by hæmorrhage after its introduction, showing that the os internum had been thoroughly dilated and the incision had healed sufficiently so that no blood followed the use of the sound After the sound was introduced I used a large glycerine tampon for the purpose of depletion and relief from irritation and to support the uterus, if it was an inversion it would hold the fundus up so as to assist in relieving the flexion to a certain extent at least, and preventing the occurrence of inflammation I have treated a great many cases in this way and with entire satisfaction, and never had a case of acute inflammation of any kind occur as the result I believe, however that a majority of cases of flexion are attended with versions more or less I don't believe that flexions occur so frequently as is generally supposed, unaccompanied with version, the uterus is tipped over more or less in connection with the flexion, and in connection with the treatment which I have suggested I have always corrected the version, and used the ordinary support or pessary to keep the uterus in its proper place, thereby relieving any contraction or pressure which would keep up the flexion I think the paper an admirable one, and the Doctor's precautions in the use of the instrument he has advised, commendable

Dr H C Feeder said I would like to ask for information In the report of these sixty cases of inversion and retroversion it has not been stated how many were accompanied by prolapsis, or what was the cause of flexion, whether in married women getting up too soon after confinement, or whether from acute inflammation The paper does not go into the facts and state whether the uterus is lightened and thereby goes back of itself to a normal position, nor does it inform us if this could be assisted by giving medicine internally Much depends upon the state of the patients at the time of treatment, whether they are in a healthy condition, or whether they have some specific blood disease in which medicine would assist in the treatment And if the medicine has an alterative effect, how much benefit is received from the medicine and how much from the pessary

Dr Jackson said, in concluding the discussion, that he felt that he ought to express his thanks for the courtesy with which his paper had been received It was only a thirteen minute paper, and there are a great many things in the domain of medicine that are not in it, and a great many questions might be asked on subjects growing out of and connected with it, which he could not answer if he were disposed to The intention of the paper is simply to demonstrate the efficacy of a single remedy in correcting a single deformity Questions as to whether the uterus was prolapsed, whether the patients had taken antibilious pills, or had cachexia, really do not enter into the consideration of the subject I supposed that was perfectly plain from the fact that no mention was made of anything beyond the mere condition of deformity I am very glad so many excellent ideas have been added to it The suggestion of Dr Nelson as to the patient being able to withdraw the pessary is excellent, and is never omitted I never introduce a pessary that I do not attach to it a silken cord by means of which the patient can withdraw it in case of necessity As a rule, every patient should be able to withdraw any instrument placed in the genital passages, the regular attendant may not be at hand when needed, there may be an aversion on the part of the patient to calling in another physician, and she should have the proper means at her disposal The remarks of Dr Dudley as regards the distinction that should be made between pathological and physiological conditions resulting in flexion, are quite proper, and I agree with him fully We all know that the conditions preceding and accompanying these bent conditions of the uterus are very various, and in many cases no stem, incision, or other means will have a beneficial effect, although they may for a time cause the uterus to be straight But the mere straightening is not always the main element of cure When the uterus has been chronically flexed there will be a thinning of the side towards the angle, showing local failure of nutrition, either as cause or effect of the bending Straightening, therefore, is one element of cure in a uterus where there is insufficient nutrition, and I do not believe that any other means exclusive of this cures flexion But it must not only be straightened, but its circulation must be fully restored, otherwise the organ will resume its bent condition We cannot put a splint on the outside of the uterus, and the intra uterine stem affords a means by which the uterus may be kept straight enough to allow of circulation on each side The method of treating flexions by forcible and extensive dilatation does more than dilate It straightens, also A bend may be just as acute in a large tube as in a small one, and mere stretching will not suffice, and its results usually not be permanent Gradual dilatation is much more promising, and next to the method by the stem I would prefer it I have only treated cases of flexion in which dysmenorrhœa was present, a symptom that interferes with the patient's health, and the dysmenorrhœa was usually cured or relieved I do not think this such wonderful success, only about two-thirds of the cases were cured, some were simply improved, and in some I do not know the result Yet I think there is no other method that will do quite as well The suggestions made in the discussion accounting for the safety and success of the treatment are, I think, correctly attributed to the preliminary measures —the slowness of the straightening and the promptness with which any tendency to harm could be met The object was to accustom the uterus to its tenant, so that by and by it would accommodate a larger one and in this way the uterus has been made to receive, and tolerate the presence of an inflexible instrument In one case a Chambers' stem was retained twenty months, and I think if the patient had not returned and told me she was wearing it it would be there yet It produced no unfavorable symptoms

Dr A R Small reported

A CASE OF PISTOL-SHOT WOUND

On May 2, 1886, he was called to see F R , aged 23, who, a few minutes previously, had received a shot from a No 32 pistol Patient was suffering from shock, difficult breathing, and excessive pain in the left leg below the knee The ball had struck the right eighth rib, about two inches external to the costal cartilage Sensation was lost in the right leg below the knee Motion was not impaired in the right leg, though the sensation was lost below the knee The left leg was hyperæsthetic below the knee, and motion slightly impaired A drainage tube was inserted about two inches into the wound, and the wound dressed antiseptically The patient complained of no pain except in left leg below the knee, where the pain was excessive Morphia was given hypodermically in sufficient doses to control the pain Nothing was allowed the patient the first twelve hours but ice, and occasionally water About 10 P M there was evidence of internal hæmorrhage, and the patient seemed to be sinking Milk was then given in small quantities frequently The morning of the 3d he had rallied somewhat

The urine was drawn by the catheter every eight hours, and contained blood There was no expulsive force to the bladder Respiration was normal after the first two hours

On the afternoon of the 3d patient became delirious, and continued so, with occasional lucid intervals, until death, which occurred at 4 20 P M of May 4th

Autopsy five hours after death Rigor mortis well marked Unfortunately, through a misunderstanding, the undertaker had preceded us and injected his preserving fluid, so that we were unable to determine exactly the amount of blood in the right pleural cavity It must have been quite large, however, as the right lung was entirely collapsed The ball made a clean round hole through the centre of the eighth rib on the right side, about two inches from the costal cartilage, passed through the lower side of the right pleural cavity, without injuring the lung, passed through the diaphragm, right lobe of the liver, and superior portion of right kidney, and through the intervertebral foramen between the eleventh and twelfth dorsal vertebræ, on the right side of the spine, and lodged against the posterior surface of the body of the eleventh dorsal vertebra, just within the spinal cord, where it was so firmly imbedded that it could not be removed without disarticulating the spine, which, for sufficient reasons, we did not do

Though we found the right lung collapsed, respiration had been normal except the first two hours after the injury

MISCELLANEOUS

Dr G C Savage, of Jackson, Tenn , has recently been elected Professor of Ophthalmology, Otology and Laryngology in the Universities of Nashville and Vanderbilt

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY FROM JUNE 12 1886 TO JUNE 18 1886

Major J S Billings, Surgeon, granted two months' leave of absence, with permission to go beyond sea, to take effect July 9, 1886 (S O 138, A G O , June 16, 1886)

Major Wm E Waters, Surgeon, ordered from Dept East to Dept Columbia

Capt Jas C Merrill, Asst Surgeon, ordered from Columbia Bks , Ohio, to Dept Columbia, to take effect upon the expiration of his present leave of absence

Capt Saml Q Robinson, Asst Surgeon, ordered from Dept Columbia to Dept Texas

First Lieut Wm O Owen, Jr , Asst Surgeon, ordered from Dept Columbia to Dept Texas (S O 133, A G O , June 18, 1886)

Capt J V Lauderdale, Asst Surgeon, ordered for duty as Post Surgeon at Fort Concho, Texas (S O 70, Dept Texas, June 12, 1886)

Capt Edward T Comegys, Asst Surgeon, ordered for duty as Post Surgeon, at Madison Bks , Sackett's Harbor, N Y (S O 60, Div Atlantic, June 15, 1886)

First Lieut C S Black, Asst Surgeon, ordered from Ft Stockton, Texas, to Ft Clark, Texas (S O 69, Dept Texas, June 11, 1886)

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U S NAVY DURING THE WEEK ENDING JUNE 10 1886

Swan, R , P A Surgeon, detached from "Brooklyn" and wait orders

Lovering, P A , Passed Asst Surgeon, detached from Navy Yard, New York, and ordered to "Brooklyn"

Arthur, George, P A Surgeon, ordered to Navy Yard, New York

Rush, C W , P A Surgeon, detached from the "Franklin" and ordered to the "Brooklyn"

Hawke, J A , Surgeon, detached from the "Wabash" and ordered to the "Essex" July 1

Smith, Howard, Surgeon, ordered to the "Wabash" stem a dangerous instrument, and that in less careful hands than Dr Jackson's serious results will often follow My own experience in the use of it has been limited for the reason that I became alarmed from the bad reports of cases by Dr Chambers himself, the inventor of this bifurcated instrument which Dr Jackson has exhibited If the same precautions are used that are advised by Dr Jackson, I think as a rule it might be entirely harmless—no, I should hardly be able to say entirely harmless, or entirely free from danger—but I think the precautions which he has adopted have been very ingenious and would in the majority of cases prevent serious results from the intra-uterine stem His use of the bougies preceding the use of the inelastic stem, accustoming the uterine mucous membrane, or the uterus itself, to the presence of a foreign body within its cavity, is very ingenious, and a thing I should never have thought of myself Although I have tried these pessaries occasionally my great difficulty has been to keep them in the uterus, I might open them in any direction I pleased, spread the blades as widely as I pleased, and they would slip out—they caused so much uterine contraction that they would be expelled from the uterine cavity into the vagina, and I have always been disappointed in the results from their use For several years while I was in active practice I had adopted the treatment of Peasley, for flexion and stenosis, whether caused by exudation or spasmodic contraction of the os internum, that is by the use of his uterotome dividing the stricture at the internal os, and then gradually dilate the canal until I could introduce a No 12 or 14 sound through the os internum This was introduced every second day from one week to two weeks until it ceased to be followed by pain, and by hæmorrhage after its introduction, showing that the os internum had been thoroughly dilated and the incision had healed sufficiently so that no blood followed the use of the sound After the sound was introduced I used a large glycerine tampon for the purpose of depletion and relief from irritation and to support the uterus, if it was an inversion it would hold the fundus up so as to assist in relieving the flexion to a certain extent at least, and preventing the occurrence of inflammation I have treated a great many cases in this way and with entire satisfaction, and never had a case of acute inflammation of any kind occur as the result I believe, however, that a majority of cases of flexion are attended with versions more or less I don't believe that flexions occur so frequently as is generally supposed, unaccompanied with version, the uterus is tipped over more or less in connection with the flexion, and in connection with the treatment which I have suggested I have always corrected the version, and used the ordinary support or pessary to keep the uterus in its proper place, thereby relieving any contraction or pressure which would keep up the flexion I think the paper an admirable one, and the Doctor's precautions in the use of the instrument he has advised, commendable

Dr H C Feeder said I would like to ask for information In the report of these sixty cases of inversion and retroversion it has not been stated how many were accompanied by prolapsis, or what was the cause of flexion, whether in married women getting up too soon after confinement, or whether from acute inflammation The paper does not go into the facts and state whether the uterus is lightened and thereby goes back of itself to a normal position, nor does it inform us if this could be assisted by giving medicine internally Much depends upon the state of the patients at the time of treatment, whether they are in a healthy condition, or whether they have some specific blood disease in which medicine would assist in the treatment And if the medicine has an alterative effect, how much benefit is received from the medicine and how much from the pessary

Dr Jackson said, in concluding the discussion, that he felt that he ought to express his thanks for the courtesy with which his paper had been received It was only a thirteen minute paper, and there are a great many things in the domain of medicine that are not in it, and a great many questions might be asked on subjects growing out of and connected with it, which he could not answer if he were disposed to The intention of the paper is simply to demonstrate the efficacy of a single remedy in correcting a single deformity Questions as to whether the uterus was prolapsed, whether the patients had taken antibil ous pills, or had cachexia, really do not enter into the consideration of the subject I supposed that was perfectly plain from the fact that no mention was made of anything beyond the mere condition of deformity I am very glad so many excellent ideas have been added to it The suggestion of Dr Nelson as to the patient being able to withdraw the pessary is excellent, and is never omitted I never introduce a pessary that I do not attach to it a silken cord by means of which the patient can withdraw it in case of necessity As a rule, every patient should be able to withdraw any instrument placed in the genital passages, the regular attendant may not be at hand when needed, there may be an aversion on the part of the patient to calling in another physician, and she should have the proper means at her disposal The remarks of Dr Dudley as regards the distinction that should be made between pathological and physiological conditions resulting in flexion, are quite proper, and I agree with him fully We all know that the conditions preceding and accompanying these bent conditions of the uterus are very various, and in many cases no stem, incision, or other means will have a beneficial effect, although they may for a time cause the uterus to be straight But the mere straightening is not always the main element of cure When the uterus has been chronically flexed there will be a thinning of the side towards the angle, showing local failure of nutrition, either as cause or effect of the bending Straightening, therefore, is one element of cure in a uterus where there is insufficient nutrition, and I do not believe that any other means exclusive of this cures flexion But it must not only be straightened, but its circulation must be fully restored, otherwise the organ will resume its bent condition We cannot put a splint on the outside of the uterus, and the intra uterine stem affords a means by which the uterus may be kept straight enough to allow of circulation on each side The method of treating flexions by forcible and extensive dilatation does more than dilate It straightens, also A bend may be just as acute in a large tube as in a small one, and mere stretching will not suffice, and its results usually not be permanent Gradual dilatation is much more promising, and next to the method by the stem I would prefer it I have only treated cases of flexion in which dysmenorrhœa was present, a symptom that interferes with the patient's health, and the dysmenorrhœa was usually cured or relieved I do not think this such wonderful success, only about two thirds of the cases were cured, some were simply improved, and in some I do not know the result Yet I think there is no other method that will do quite as well The suggestions made in the discussion accounting for the safety and success of the treatment are, I think, correctly attributed to the preliminary measures —the slowness of the straightening and the promptness with which any tendency to harm could be met The object was to accustom the uterus to its tenant, so that by and by it would accommodate a larger one and in this way the uterus has been made to receive, and tolerate the presence of an inflexible instrument In one case a Chambers' stem was retained twenty months, and I think if the patient had not returned and told me she was wearing it it would be there yet It produced no unfavorable symptoms

The urine was drawn by the catheter every eight hours, and contained blood There was no expulsive force to the bladder Respiration was normal after the first two hours

On the afternoon of the 3d patient became delirious, and continued so, with occasional lucid intervals, until death, which occurred at 4 20 P M of May 4th

Autopsy five hours after death Rigor mortis well marked Unfortunately, through a misunderstanding, the undertaker had preceded us and injected his preserving fluid, so that we were unable to determine exactly the amount of blood in the right pleural cavity It must have been quite large, however, as the right lung was entirely collapsed The ball made a clean round hole through the centre of the eighth rib on the right side, about two inches from the costal cartilage, passed through the lower side of the right pleural cavity, without injuring the lung, passed through the diaphragm, right lobe of the liver, and superior portion of right kidney, and through the intervertebral foramen between the eleventh and twelfth dorsal vertebræ, on the right side of the spine, and lodged against the posterior surface of the body of the eleventh dorsal vertebra, just within the spinal cord, where it was so firmly imbedded that it could not be removed without disarticulating the spine, which, for sufficient reasons, we did not do

Though we found the right lung collapsed, respiration had been normal except the first two hours after the injury

MISCELLANEOUS

Dr G C Savage, of Jackson, Tenn , has recently been elected Professor of Ophthalmology, Otology and Laryngology in the Universities of Nashville and Vanderbilt

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY FROM JUNE 12, 1886 TO JUNE 18 1886
